Extralimital. Breeds in W. Siberia in the valley of the Irtysh near Tara and in the Ob valley in the Barnaul region; in Transbaikalia (Arghun Valley) and in NW. and C. Mongolia. Complete breeding range not known. On migration and in winter to China, Japan, N. India, Burma, and the Indochinese countries. Borneo (Smythies).

MIGRATION. No data. The specimens obtained near Shillong, c. 1500 metres elevation, in early September and late April were presumably on passage.

GENERAL HABITS, FOOD, VOICE and CALLS. Apparently similar to the Godwits (389, 391) but no precise data.

BREEDING. Extralimital. Poorly known.

MUSEUM DIAGNOSIS. See under genus; for details of plumage, Baker loc. cit.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂♂	160-172	77-87	48-54	61-67 mm. (Baker)
♀♀	163-177			

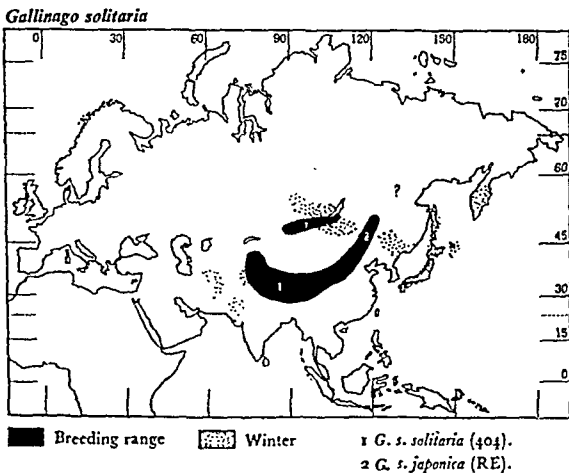

6 ♂♀ recently ringed at Chilka lake gave Wing (in flesh) 177-181 mm.; weight 127-147 gm. (SA).

COLOURS OF BARE PARTS. Iris dark brown. Bill black, paler and plumbeous at base. Legs and feet dark plumbeous or brownish black.

SIZE. Grey Quail +; larger than Fantail Snipe. Length (including bill) c. 31 cm. (12 in.).

FIELD CHARACTERS. A typical, concealingly coloured marsh bird — variegated brown, black, rufous, fulvous, and white — with a straight slender bill about 7 cm. (3 in.) long. Difficult to tell from other snipe (unless in the hand), but large size, paler coloration, solitary habit, and mountain habitat suggestive. See Key and Museum Diagnosis. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Found in summer throughout the Himalayas, between c. 2800 and 4600 m. elevation. Nowhere common but probably breeding locally: Ladakh, Kashmir and through Himachal Pradesh, Kumaon, Garhwal, Nepal, Sikkim, Bhutan to extreme NE. Assam; descending to lower levels and foothills in winter. Recorded in winter as rare visitor or erratic vagrant in the Assam hills south of Brahmaputra river, Manipur, northern W. Bengal, Banaras (U.P.), Chilka lake (Orissa). An old record

from Wynaad (Kerala-Mysore) is doubted by Whistler. Recorded also in West Pakistan (north Baluchistan Hills — Quetta etc., and Chitral) and E. Pakistan (Dinajpur, Rangpur, Chittagong Hill Tracts). Affects sprawling boggy mountain streams, often half frozen, interspersed with spongy grass hummocks and rhododendron, berberis and such-like scrub. Also wet scrub-bordered paddy stubbles among the hills (Assam).

Extralimital. 'Breeds in central Asia at high elevations from Tarbagatai, the Sayan and Khangai Mtns. south to the Tian Shans and Himalayas, east to Koko Nor and Upper Burma. Chiefly resident but descending to lower levels in winter' (Peters).

MIGRATION. No data.

GENERAL HABITS. Terrestrial; solitary; swamp-dwelling, usually at high elevations in the Himalayas. Two or three widely separated individuals occasionally flushed on the same bog. Flight somewhat slower and heavier than Common Snipe's but with the same zigzag twists and turns. Seldom flies far before resettling, even after being fired at.

FOOD. Worms, grubs, minute snails, etc.

VOICE and CALLS. A characteristic *scoop* or *pench*, uttered as the bird flushes; very like the Common Snipe's but deeper and harsher. No other calls recorded.

BREEDING. Extralimital and curiously little known. No authentic record of nest and eggs within our limits, but 'doubtless breeds' in the Puga Valley in Rupshu (Ladakh) vide Ludlow (JBNHS 27: 146).

MUSEUM DIAGNOSIS. Coloration paler than *nemoricola* (405); bill appreciably longer and less stout. Wing exceeds 150 mm.; outer edges of scapulars broadly white; middle upper tail-coverts unbarred pale olive-brown.

For description of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂♀	153-169	67-77	c. 28-38	55-63 mm.

Depth of bill at base 8-9 mm. (Baker)

Weight 5-8 oz. (c. 142-227 gm.). — Hume.

COLOURS OF BARE PARTS. Iris brown. Bill olive-brown, blackish on terminal third of upper mandible and half of lower. Legs and feet olive; claws horny brown.

405. Wood Snipe. *Gallinago nemoricola* Hodgson

Gallinago nemoricola 'Ej.' = Hodgson, 1836, Proc. Zool. Soc. London: 8 (Nepal)

Baker, FBI No. 2168, Vol. 6: 255

LOCAL NAMES. *Chāhā* (Hindi, for all snipe); *Bān chāhā* (Bengali); *Kāttu allān* (Tamil — Madurai).

SIZE. Grey Quail +; length (including bill) c. 31 cm. (12 in.).

FIELD CHARACTERS. Above, dark brown, concealingly patterned with black, rufous, and buff streaks. Below, breast fulvous barred with brown; rest of underparts, including abdomen, white closely barred with brown. Sexes alike.

Can usually be distinguished from the commoner Pintail and Fantail snipes (406, 409) by larger size, much darker coloration and comparatively slow flight with bill pointing downwards; also by its more wooded and hilly habitat.

STATUS, DISTRIBUTION and HABITAT. Throughout the Himalayas from Dalhousie in Himachal Pradesh (c. 76°E.) east through Nepal, Sikkim, and Bhutan to extreme NE. Assam. Rare west of Indus river; once at Mardan in Peshawar district, c. 72°E. (Barton, JBNHS 14: 606). In summer between c. 1300 and 3700 metres and possibly higher. A specimen taken in SE. Tibet on September 1 at c. 4300 m. (Ludlow, 1944, *Ibis*: 387). Below c. 1200 m. in the Himalayas status uncertain; may be resident in parts.

CURLEWS, SANDPIPERS, SNIPE, WOODCOCK 281

In winter at lower elevations in the Himalayas, and visitor to the peninsular and south Indian hill ranges: recorded in northern W. Bengal, Manipur, Orissa, Madhya Pradesh, Andhra, Maharashtra, Mysore, Madras, and Kerala; apparently occurring regularly in small numbers. Rare vagrant in Ceylon. Doubtless also occurs in Chittagong Hill Tracts, E. Pakistan. Affects swampy patches, pools and puddles amidst tall grass and scrub in hilly country — cover too thick for Common Snipe.

Extralimital. Eastward through Burma to the southern Shan States.

MIGRATION. No data.

GENERAL HABITS. An essentially montane species. Keeps singly, but two or three not infrequently flushed close to one another in swampy patches under waist-high grass and scrub. Flight slow and wavering, reminiscent of both Painted Snipe and Woodcock — well described as 'owlish' or 'bat-like' — also like the latter with bill pointing downwards. Flops into cover again like a rail after fifty or a hundred metres. Far easier shooting than Pintail or Fantail Snipe, but its smaller numbers, irregularly scattered over far-flung pockets of appropriate habitat, makes sizeable bags impossible.

FOOD. Worms, small aquatic insects and grubs. Tiny hard black seeds, probably accidentally taken, and gravel have been found in stomachs (Hume & Marshall).

VOICE AND CALLS. Often flushes silently; occasionally with a low croaking note like *tek-tek*. This together with the other field characters (above) should help to establish its identity.

BREEDING. Strangely enough no first-hand authentic record of nest and eggs available. Baker's Khasi egg collector brought him a single egg with skin of a female snared on the nest. They were taken on 11 June¹ 1908 in pine forest between 1700 and 1850 metres altitude. The egg is described as very like Common Snipe's but more grey-brown in tint. No further information in the last 60 odd years!

MUSEUM DIAGNOSIS. The barring on the underparts extending down to abdomen together with its general duskiness gives the bird a 'woodcocky' appearance. Distinguished from Woodcock by the longitudinal stripes on head (*contra* bold transverse bars) and attenuated outer tail-feathers. Buff borders to scapulars and large size differentiate it from Pintail and other snipes with attenuated outer rectrices. For details of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	133-141	61-67	c. 30-36	63-74 mm.
	(Baker)			
	Depth of bill at base c. 12-13 mm.			

Weight c. 5-7 oz. (c. 142-198 gm.). — Various authors.

COLOURS OF BARE PARTS. Iris dark brown. Bill horny brown tinged green, darker at tip, yellowish on basal two-thirds of lower mandible. Legs and feet dark plumbeous green.

¹ The Fauna gives the date as 16 June.

CURLEWS, SANDPIPERS, SNIPE, WOODCOCK 283

paddyfields with puddles here and there, scrub-dotted grazing grounds, and even lantana-covered hollows.

Extralimital. Breeds in E. Siberia west to the Yenisey, north to c. lat. 67°, south to E. Turkistan (?), N. Tibet, the upper Hoang-ho, Amurland, and Sakhalin. Winters in India, [Burma], Indochinese countries, S. China, Hainan, Formosa, the Greater Sunda Is., and Timor (Peters).

MIGRATION. No ringing data. First birds of the season normally begin to arrive about end August or early September, not only in the north (Assam, Bengal, Sind) but simultaneously also elsewhere in the Peninsula to the south, and in the Andamans and Ceylon. The majority have departed again by early April, a few lingering on into May. Arrival in different localities depends on phenological conditions, extralimital as well as local, subject to variation from year to year. Therefore the map of approximate dates of arrival given by Baker, 1921 (*Game Birds of India, Burma and Ceylon* 2: 97) must be taken only as diagrammatic.

GENERAL HABITS. Usually flushed singly; also in wisps of 3 and 4 in patches where food is plentiful, and in larger wisps, even flocks, early in the season when the birds have just arrived, and again preparatory to emigration. Can seldom be spotted as it crouches on the ground due to its astonishingly obliterative coloration. When disturbed rises abruptly, often from almost under foot, uttering the harsh characteristic note — *scope* or *pench* — and goes off at a tremendous pace in a series of angular zigzags. It is this lightning zigzag flight that provides the element of sport to snipe shooting, and disappointing bags to mediocre shots! Feeds in the squelchy mud, chiefly in the morning and evening and through the night. Is less active during the heat of the day, retiring into shade under grass tussocks or bushes bordering its feeding marsh — sometimes among thickets on higher ground well away. Very active on cool windy days. On such will often flush while still out of gunshot, mount high in the air and circle widely overhead flying at great speed with its peculiar angular rolling movements, calling from time to time, and soon drop or shoot down to earth again close to where it rose. Like all snipes, feeds by probing with its slender bill into soft mud. Under-ground prey located by means of the sensitized flexible tip which opens like forceps to seize the quarry.

FOOD. Chiefly worms, larvae and tiny molluscs.

VOICE AND CALLS. A harsh nasal *scope* or *pench* uttered as it flushes; also in flight every second or so in the initial spurt and with longer pauses when well under way. This call closely resembles the sucking sound of a sodden shoe, which is so deceptively alerting when walking up snipe on marshy ground!

BREEDING. Chiefly extralimital. Exceptional cases of breeding recorded in Assam and E. Pakistan three or four times (N. Cachar, Sylhet-Cachar border, Barail Range, Silchar) presumed by Baker to be of pricked birds disabled from migrating. Reports need confirmation. Nest and eggs similar to those of Fantail Snipe (409), q.v.

MUSEUM DIAGNOSIS. Tail-feathers 26 or 28, of which 8 or 9 outer ones on each side much attenuated and stiff ('pins'). Under wing-coverts and axillaries much more heavily and darkly barred than in *Gallinago gallinago* (409). For details of plumage see Baker, loc. cit.

406. Pintail Snipe. *Gallinago stenura* Bonaparte

Scelopax stenura Kuhl = Bonaparte, 1830, Ann. Stor. Nat. Bologna 4: 335 (Sunda Islands)

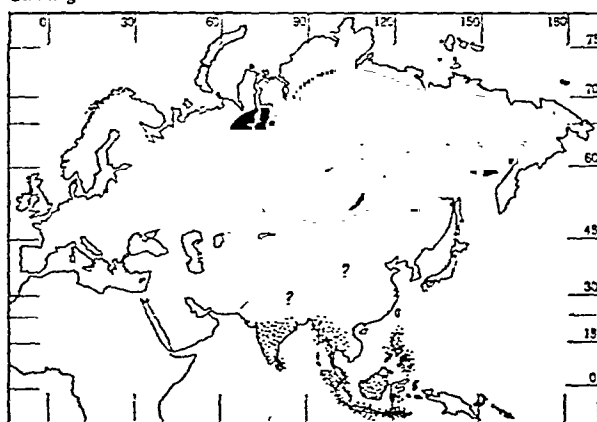

Baker, FBI No. 2173, Vol. 6: 263
Plate 41, fig. 15

LOCAL NAMES. Same as for Common or Fantail Snipe (409); *Kedakhocha* (Bengal).

SIZE. Grey Quail +; length (including bill) c. 27 cm. (10½ in.).

FIELD CHARACTERS. As of Fantail Snipe (409), q.v. Slightly darker, and heavier on the wing with a less zigzag flight, and often frequenting drier ground. But field identification difficult and unreliable except perhaps by very experienced snipe shooters. A consistent peculiarity observed while ringing snipe for migration study is that the Pintail nearly always 'squeals' when handled, whereas the Fantail hardly ever does so. Sexes alike; female slightly larger. See Key and Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Winter visitor to both Pakistans and all India, Nepal (Valley and (?) terai), Sikkim and Bhutan duars, Ceylon, Andaman, Nicobar and Maldivic islands; plains level to c. 2500 m. About equally abundant with Fantail Snipe in the eastern areas, viz. Assam, Bengal, East Pakistan, but overwhelmingly more so in South India, Andaman Is. and Ceylon. In the western and northwestern parts of the subcontinent the Fantail is relatively more numerous. Affects marshy

Gallinago stenura

■ Breeding range ····· Winter

edges of jheels, wet paddy stubbles (inland as well as those under tidal influence), seepage marshes from dammed reservoirs in the foothills, and the like, sharing these with Fantail Snipe. But oftener frequents harder ground than Fantail — damp rather than marshy, e.g. harvested

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂♂	125-134	57-61	29-31	c. 54-68 mm. (Baker)
♀♀	130-138	59-64		

Baker's tail measurements are erroneous. Specimens in the Bombay Natural History Society's collection, and others collected recently, give ♂ ♀ tarsus 32-36 (5 measured), tail 45-52 mm. (13 measured).

Weight c. 3 to 4½ oz. (c. 85-134 gm.). Average of 472 birds (♂ ♀) in South India 4 oz. (c. 113 gm.). — Stoney. 12 ♂ ♀ (winter, Bihar) 89-123 (av. 99.9) gm. — BNHS.

COLOURS OF BARE PARTS. Iris brown. Bill horny brown, pale greenish on gonyx and base of lower mandible. Legs and feet greyish green; claws dark brown.

MISCELLANEOUS. Statistics of relative abundance of Pintail and Fantail Snipe in the erstwhile Madras Presidency collected by Mr R. F. Stoney from shooting tables for 37 seasons (1898-9 to 1934-5) confirm the overwhelming preponderance of the Pintail in South India. During this entire period 15 330 Pintails were shot against 2312 Fantails. During the 10 seasons 1925-5 to 1934-5 3644 Pintails were shot at Cannanore, Malabar (now Kerala), against 856 Fantails (Phythian-Adams), while during 12 seasons (1923-4 to 1934-5) 526 Pintails were shot on the Nilgiri Plateau against only a single Fantail by the same sportsman.

Several instances of partial to almost complete albinism have been recorded in this as well as Fantail Snipe in India.

407. Swinhoe's Snipe. *Gallinago megala* Swinhoe

Gallinago megala Swinhoe, 1861, Ibis: 343 (Between Takoo and Peking, China)
Baker, FBI No. 2174, Vol. 6: 264

LOCAL NAMES. Same as for Common or Fantail Snipe (409).

SIZE. Grey Quail +; length (including bill) c. 29 cm. (c. 11 in.).

FIELD CHARACTERS. Indistinguishable from Pintail Snipe (406) except in the hand, for which see Key and Museum Diagnosis. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. A comparatively uncommon but regular winter visitor between September and March: recorded from Assam, Manipur, W. Bengal, Madras, Mysore, Kerala, Ceylon, Maldivic and Andaman Is., Bombay (JBNHS 67: 108). Possibly less rare than assumed, due to lack of careful vetting of bags of Pintail among which very liable to be overlooked. Affects the same habitats as Pintail.

Extralimital. Breeds in east-central Asia from southwestern Transbaikalia to Amurland, south to N. Mongolia, the upper Hwang ho and Usuri; Sakhalin (?). Migrates through E. China and Japan; winters in Burma, the Philippines, Borneo, Celebes, the Moluccas and N. Australia (Peters). For details see Vaurie, C., 1965, 2: 433. Recorded as very abundant in ricefields in the Philippines 'at certain seasons'.

MIGRATION. No data. Eastern and southern India apparently lie on the extreme western fringe of its winter range.

GENERAL HABITS, FOOD, VOICE AND CALLS. Nothing recorded as different from Pintail Snipe.

CURLEWS, SANDPIPERS, SNIPE, WOODCOCK 285

Gallinago megala

■ Breeding range ▨ Winter

BREEDING. Extralimital. (For a good account of its aerial nuptial display and song in N. Mongolia, see Kozlova, E. V., 1932, *Ibis*: 580.)

MUSEUM DIAGNOSIS. Coloration above and below (including white centre of abdomen) confusingly similar to Pintail Snipe (406). Most easily differentiated by its tail of 20 feathers of which only the central 6 are broad (of normal shape), the rest on either side attenuated. See also Key to the Species. Another good diagnostic character, especially when tail in moult or damaged, is length of bastard wing.

Bastard wing always over 19 mm.....*G. megala*

Bastard wing always under 19 mm.....*G. stenura*

Some superficial characters, suggested by an experienced snipe-shooter (R. J. Clough) to assist picking out at a glance suspected Swinhoe's Snipe from among a bag of Pintails for more critical examination are:

1. 'Definitely' larger size
2. Longer legs
3. Longer and slenderer bill, with the white knob at tip of upper mandible less pronounced.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	128-139	59-74	♂ 32-34	52-57 mm.
				(Baker)
♂ ♂	147-150	61-65	32.5-35	55-62 mm.
♀ ♀	142-151	64-72	33-35 (once 37, once 38)	

(La Touche)

COLOURS OF BARE PARTS. 'Iris dark umber-brown; bill light yellowish brown for the basal two-thirds, yellower on the base of the upper mandible, blackish brown

CURLEWS, SANDPIPERS, SNIPE, WOODCOCK 287

Gallinago media

■ Breeding range ▨ Winter

GENERAL HABITS, FOOD, VOICE AND CALLS. Nothing observed in India as different from Fantail or Pintail Snipe. Elsewhere reported as more crepuscular, and occasionally uttering a low guttural croak on flushing.

BREEDING. Extralimital.

MUSEUM DIAGNOSIS. See Key to the Species. For details of plumage Baker, loc. cit.; for plumage phases and morphology (also bionomics), Witherby, 1940, 4: 193-7.

MEASUREMENTS —

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♂	140-150	57-63	33-37	51-59 mm.
♀ ♀	139-149	64-69	—	(Witherby)

COLOURS OF BARE PARTS. Iris dark brown. Bill brown or horny brown. Legs and feet dusky plumbeous or greenish plumbeous (Baker).

409. Common or Fantail Snipe. *Gallinago gallinago gallinago* (Linnaeus)

Scelopax Gallinago Linnaeus, 1758, Syst. Nat., ed. 10, 1: 147 (in Europa = Sweden)
Scelopax (Gallinago) gallinago raddei Buturlin, 1912, Psovaia i Ruzheinaia Okhota, author's reprints, p. 54 (East Siberia)

Baker, FBI No. 2170, Vol. 6: 259
Plate 41, fig. 13 and Plate 43, fig. 11

LOCAL NAMES. *Chhā* (Hindi); *Chegga*, *KadaUchoa* (Bengal); *Khocha sorāi*, *Chhā sorāi*, *Chergga* (Assam); *Bhādrā* (Nepal); *Chiklaobi* (Manipur); *Afor uddā*, *Uddā kīrī*, *Chiklaobi*

CHARADRIIFORMES

on the apical third; feet light yellowish grey with blackish brown claws' (Swinhoe). 'Iris chestnut. Legs and feet bluish plumbeous' (Venning).

MISCELLANEOUS. In South India where both this species and Pintail occur together, Lt-Col. E. G. Phythian-Adams found Swinhoe's Snipe proportionately less common in Mysore than in Malabar (Kerala). His bag record for 14 years (up to 1939) showed

Mysore: 1973 Pintail to 3 Swinhoe's, i.e. 1 to 658

Malabar: 5321 Pintail to 19 Swinhoe's, i.e. 1 to 280

408. Great Snipe. *Gallinago media* (Latham)

Scelopax media Latham, 1787, Gen. Syn., Suppl.: 292

(England; based on Gen. Syn. 3(1): 133, no. 4)

Baker, FBI No. 2172, Vol. 6: 261

SIZE. Fantail Snipe +; length c. 28 cm. (c. 11 in.).

FIELD CHARACTERS. Slightly more robust in build, darker, and more heavily barred below than Fantail Snipe, but doubtfully distinguishable from it at rest. In flight — which is slower, less zigzag, and usually unaccom-

Half tail, x c. 1
G. media *G. gallinago*

panied by the characteristic flushing note *pench* — the large amount of white in the tail (outside feathers) is at once striking. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Rare vagrant. Has so far only been obtained in southern India (Bangalore, Nilgiris, Arkonam, Madras). Also in Ceylon and Andaman Is. All September-March.

Extralimital. 'Breeds in N. Europe and W. Asia from N. Norway, S. Finland, the White Sea and the lower Yenisey, south to Denmark, E. Prussia, Poland, Bessarabia, Kirghiz Steppes and the Altai. Migrates through S. Europe and SW. Asia; winters in Africa south of the Sahara, mainly in the east' (Peters). For details see Vaurie, C., 1965, 2: 432.

MIGRATION. No data.

CHARADRIIFORMES

Korā kūthi (Tamil); *Muku pardi* (Telugu); *Keswatuwā* (Sinhala); *Dao didap* (Cachar); *Voh ti alin* (Kuki); *Ti inrui* (Naga); *Lik pokhi* (Sind); *Chuntan kata* (Malayalam); *Garkhod* (Gujarati); *Pān lawa* (Marathi). Commonly understood as 'ishnāp' or 'ishnāf'.

SIZE. Grey Quail +; length (including bill) c. 27 cm. (10½ in.).

FIELD CHARACTERS. A brown obliteratively patterned marsh-haunting bird with straight slender bill about 6 cm. (2½ in.) long, difficult to observe when squatting motionless on the ground. Renowned for its habit of rising suddenly when disturbed, with a hoarse *scape* or *pench* note, and flying off in lightning zigzags. Above, dark brown, heavily streaked with black, rufous, and buff; below, whitish. Impossible to distinguish from Pintail Snipe (406) by non-experts unless in the hand, but usually frequents more squelchy ground. See Key and Museum Diagnosis. Sexes alike.

Young (immature) like adult but sometimes recognizable by whitish fringes to mantle feathers and wing-coverts.

For downy chick see Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Partly resident in the Himalayas (Kashmir, Garhwal, etc.); chiefly a common and abundant winter visitor to the entire subcontinent including both Pakistans and Nepal (Valley and ?) terai). Also Ceylon, Andaman and Maldivé islands. Relatively

Gallinago gallinago

■ Palearctic and African breeding range ▨ Winter

much less numerous than Pintail Snipe in southern India; more so in the western and northwestern parts, and in W. Pakistan. Affects swampy edges of jheels, seepage marshes from dammed reservoirs, squelchy harvested paddyfields, etc. — on the whole softer ground than preferred by Pintail. Occasionally seen on bare edges of exposed village ponds in proximity of women washing and cattle watering!

CURLEWS, SANDPIPERS, SNIPE, WOODCOCK 289

Extralimital. 'Breeds in Europe and Asia from Scandinavia to eastern Siberia, north to lat. 66°30' to 70°, south to the British Isles, Pyrenees, the Alps, [erstwhile] Balkan States, Caucasus, Kirghiz Steppes, the Pamirs, Himalayas, Transbaikalia, the Amur River, Hokkaido and the Kurile Is. Winters in the southern parts of its breeding range, Mediterranean region, Egypt, E. Africa south to Kenya; Persia, India, Indochinese countries, S. China, Japan, and the Greater Sunda Is.' (Peters).

MIGRATION. No ringing data. On spring emigration passes through the Kurram Valley (NW. Pakistan) from the last week of January till mid April (Whitehead). See remarks under Pintail which are generally applicable also to this species. The migration routes and approximate arrival dates shown on the map in Baker, 1921 (*Game Birds* 2: 63) are largely diagrammatic and must not be taken too literally.

GENERAL HABITS, FOOD, VOICE AND CALLS. As of Pintail Snipe (406), q.v. The harsh nasal flushing note of the two species — *scape* or *pénch* — are indistinguishable to the normal ear.

BREEDING. *Season* in the Kashmir Valley, Garhwal, and elsewhere in the Himalayas at elevations between c. 1600 and 4500 m., from late April to about mid June. *Nest*, a scanty concave pad of grass and weed stems, etc., c. 10 cm. across, concealed among arching grasses or thick herbage in a spongy or semi-floating bog. *Eggs*, normally 4 — occasionally 3, rarely 5 — greyish stone to olive-grey or yellowish brown in ground colour, irregularly blotched and speckled all over with dark brown, more densely at the broad end. They have secondary markings of grey, sienna, or pale purplish brown. Shape variable from broad to longish pyriform, and size absurdly large for the bird. Average of 60 Indian eggs 38.3 × 28.5 mm (Baker). Both sexes believed to share in incubation; period recorded as 19–20 days. The bird is a close sitter, often permitting the observer's hand to approach within a few centimetres before leaving the nest, then usually flying off in a semi-circle at top speed. In nuptial display male mounts rapidly on fluttering wings to height of 50 to 100 metres, flies about in rambling zigzags and wide circles at top speed uttering *chip-per*, *chip-per*, etc., punctuated by steep nose-dives with wings pulled in and tail fully fanned out. The outermost rectrix on either side sticks out widely separated from its neighbour and vibrates rapidly with the through rush of air, producing the peculiar loud drumming or bleating sound which gives the bird one of its popular German names meaning 'goat of the sky'. Each flight lasts for five minutes or more, and covers an extensive area of the breeding marsh in wide circles at a furious tempo. Thereafter the performer drops or shoots to the ground at a steep angle with wings pulled in, fluttering to break the fall just before alighting.

MUSEUM DIAGNOSIS. See Key to the Species; for details of plumage, Baker, loc. cit.; for description of plumage phases and morphology (also bionomics), Witherby, 1940, 4: 197–203.

Chick (in down). 'Down of upper plumage rufous-buff; a band across the forehead yellow-buff; crown freckled with black and with two broad bands of black on either side of the crown; a line through the eye and another on the cheek black; dorsal, median, and lateral lines black, the down white-speckled at the tips; wings broadly marked with black and a black patch on the side of the breast and on the flanks; lower parts rufous-buff' (Baker).

* See Appendix

CURLEWS, SANDPIPERS, SNIPE, WOODCOCK 291

Gallinago minima

■ Breeding range ▨ Winter

Extralimital. 'Breeds in N. Europe and Asia from N. Norway east to the Kolyma Delta (apparently nowhere north of 70°), south to Denmark, E. Prussia, Baltic States, central Russia, and the forest steppe of Minusinsk; southward limit in W. and E. Siberia not known. Winters in W. Europe, Mediterranean region, Egypt, Iraq, Persia, India, Burma; casually to Nigeria and Kenya' (Peters). For further details see Vaurie, C., 1965, 2: 436.

MIGRATION. No ringing data. In Baluchistan and Sind in autumn 'it is much later in arriving [than Fantail or Pintail Snipe] and the end of the first week in October would seem to be the earliest date' (Ticehurst). In northern Baluchistan it is particularly common on spring (outward) passage, Meinertzhagen having seen more than 100 birds in a day. It passes through the Kurram Valley (NW. Pakistan) in varying numbers, less than Fantail, from the last week in January till the middle of April (Whitehead).

GENERAL HABITS. Similar to Fantail and Pintail Snipe, but almost invariably flushed singly and not in wisps as the others often are. Is reluctant to leave cover; rises silently, without the characteristic *scape* or *pénch*, only when almost trodden on, dropping into the reeds again after a short flight unlike the Fantail's zigzagging to a height and then shooting down steeply to the ground. Somewhat slower flight and less abrupt twists and turns afford easier shots to the sportsman.

FOOD. Mainly worms, tiny molluscs, insects and their larvae. Also seeds of marsh plants.

VOICE AND CALLS. Not recorded in India. Display-note in breeding season (presumably vocal) likened to the distant cantering of a horse on hard hollow ground.

290

CHARADRIIFORMES

MEASUREMENTS

9 ♂♀	Tail 54–64 mm. (av. 57.7)			

(SA)

COLOURS OF BARE PARTS. Iris dark brown. Bill yellowish horny or olive-yellow on basal half, dark horny brown to blackish on terminal half. Legs and feet dull olive-green, more yellow in breeding season.

MISCELLANEOUS. Four cases of complete or partial albinism have been recorded in the *Journal of the Bombay Natural History Society*. Longevity (from ringing records) 7 years (Ring, 1962, 33: 149).

410. Jack Snipe. *Gallinago minima* (Brünnich)

Scolopax Minima Brünnich, 1764, Orn. Boreal: 49 (E. Christiansø, Denmark)

Baker, FBI No. 2175, Vol. 6: 265

Plate 43, fig. 10

LOCAL NAMES. *Chhōta chhōla* (Hindi); *Chhōta bhārkā* (Nepal); *Ullān* (Tamil); *Dō Lāgān* (Bihari mirshikars).

SIZE. Fantail Snipe —; Grey Quail ±; length (including bill) c. 21 cm. (8½ in.).

FIELD CHARACTERS. Similar to Fantail Snipe but considerably smaller with relatively shorter and stouter bill and much metallic green and purple sheen in the streaked dark brown upper plumage. Tail rather wedge-shaped,

× c. 1

uniformly dark, lacking Fantail's whitish tips to outer rectrices; crown without the central stripe of other snipes. Sexes alike. Flushes silently and has rather sluggish flight without the abrupt zigzags.

STATUS, DISTRIBUTION AND HABITAT. Winter visitor in much smaller numbers than Fantail and Pintail Snipe, irregularly throughout the Indian Union, both Pakistans, Nepal. Occasional in Ceylon and Andaman Is. Affects the swampy marginal zone around jheels, seepage marshes, and waterlogged harvested paddyfields — as with Fantail Snipe more squelchy ground than normally frequented by Pintail.

292

CHARADRIIFORMES

BREEDING. Extralimital; in general as in the Fantail (409).

MUSEUM DIAGNOSIS. Tail of 12 feathers, more or less uniformly dark brown with rufescent-buff borders. Central pair pointed and projecting slightly beyond the others, as e.g. in the Little Stint (416). No median pale coronal stripe. Plumage of back and scapulars with an iridescent purple and green gloss. Gape more or less in line with the bases of the upper and lower mandibles. Culmen somewhat swollen at base. For details of plumage see Baker, loc. cit.; for description of plumage phases and morphology (also bionomics), Witherby, 1940, 4: 205–9.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂♂	108–117	39–41	23–25	46–51 mm.
♀♀	107–115	40–43	—	—
				(Witherby)

Weight 40 ♂♀ (autumn/winter) 39–55 (av. 46.5) gm. — BNHS.

COLOURS OF BARE PARTS. Iris dark brown. Bill almost black at tip, paling posteriorly to horny brown; olive, greenish horny, or flesh coloured at base and gape. Legs and feet pale olive-green, often tinged with yellowish or grey.

MISCELLANEOUS. An indication of the relative scarcity of the Jack Snipe in South India is provided by the game records maintained by the late Mr R. F. Stoney for 37 seasons — from 1898 to 1935. Of the total number of snipe shot during this period 13,530 were Pintails, 2312 Fantails, and only 126 Jacks.

Genus *SCOLOPAX* Linnaeus

Scolopax Linnaeus, 1758, Syst. Nat., ed. 10, 1: 145. Type, by tautonymy, *Scolopax rusticola* Linnaeus (*Scolopax prebinomial* specific name in synonymy)

Bill long, slender, rather soft and swollen at tip; both mandibles grooved. Nostril linear, at base of upper mandible. Gape forward of base of culmen. Wings long: first primary (as.) longest. Tail-feathers 12; short and soft. Legs short; tibia fully feathered.

The genus contains a single species represented in India by the nominate race.

411. Woodcock. *Scolopax rusticola rusticola* Linnaeus

Scolopax Rusticola Linnaeus, 1758, Syst. Nat., ed. 10, 1: 146

(Europe, restricted type locality, Sweden)

Scolopax indicus Hodgson, 1837, Jour. Asiat. Soc. Bengal 6: 490 (Nepal)

Scolopax rusticola ultimis Koels, 1954, Contrib. Inst. Regional Exploration No. 1: 31 (Sanganu, Lushai Hills)

Cf. Hartert, E., 1921, Vog. pal. Fauna 2: 1651–4

Baker, FBI No. 2167, Vol. 6: 252

Plate 41, fig. 14 and Plate 43, fig. 13

LOCAL NAMES. *Sintetār*, *Tutetār* (Hindi); *Sin kēlā* = 'hill, or spring fowl' (Kumaon and Nepal); *Chinjarele* (Chambas); *Doodidap gedra* (Cachar); *Sin-pochhlaz* (Khasi); *Sēbel kēdrūt* (Manipur); *Wileiti chāla* (Chittagong); *Bur-pel*, *Dakha* (Chitral); *Chetā* (Drosh); *Chētrūt* (Gulgi); *Zār kēchi* (Kashmir).

SIZE. Partridge —; length (including bill) c. 36 cm. (14 in.).

CURLEWS, SANDPIPERS, SNIPE, WOODCOCK 293

FIELD CHARACTERS. An outsized snipe, camouflagingly mottled brown, black, and whitish with the characteristic long slender straight bill—soft and swollen at tip—and comparatively short legs. *Above*, brownish grey blotched and barred with black, rufous, and buff. Hindcrown, nape and rump cross-barred black and rufous. *Below*, chin white; rest of underparts brownish white cross-barred with dark brown. Sexes alike.

In the owl-like flapping flight the bill is carried pointing downwards. When banking in the air the tail is fanned out giving the tubby body with its short curving scimitar-like wings a blunt-ended look.

For immature bird and downy chick see Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Breeds throughout the Himalayas between c. 2000 and 3800 metres—in NW. Pakistan, Kashmir, Garhwal, Kumaon, and Bhutan. Evidently also in Nepal, Sikkim, and NEFA whence as yet no actual nests reported. In winter descends to lower elevations in the Himalayas and also migrates south to the Assam hills, Nagaland, Manipur, and across the Peninsula to the Nilgiri, Palni, and associated hill ranges,

Sceloporus rusticola

■ Breeding range ■ Winter

and the moist southern strip of the Western Ghats in Kerala and Mysore. Occasional winter visitor to Ceylon in the central hill zone (c. 2000 m.). Affects swampy glades with dense scrubby undergrowth in rhododendron, fir and mixed forest in the Himalayas; dank ravines in sholas and evergreen forest, and cardamom and coffee plantations with sprawling swampy streams in South India. The clearing away of forests for potato and tea cultivation in the last forty years has progressively reduced its abundance in many of its best-known former habitats in the Nilgiris and Assam hills.

Extratropical. Breeds in the British Isles, Scandinavia (north to lat. 70°), Russia (north to lat. 66°) and across Asia (north to lat. 62°–64°), south to

CURLEWS, SANDPIPERS, SNIPE, WOODCOCK 295

take-off and has to be assisted by beating the earth with the wing-tips for a metre or so before getting clear. In flight the body is weighted down at rear to an angle of about 45 degrees. In the case observed by Col. Bates the chicks were transported one by one downhill to a distance of some 30 metres.

MUSEUM DIAGNOSIS. For description of plumage see Baker, loc. cit.; for details of plumage phases and morphology (also bionomics), Witherby, 1940, 4: 184–93.

Young (immature). Feathers of the mantle with more or less exposed brown bases and marked with buff and cinnamon-buff. Upper tail-coverts more barred, and lacking buff tips. Bars on underparts narrower and paler.

Chick (in down). From base of bill to eye, over and behind it, a narrow dark brown line; from centre of base of bill to centre of crown a dark brown line; between the two lines, creamy yellow; rest of crown pale chestnut; side of head variegated chestnut and creamy yellow, as are the wings and rest of upperparts, showing a broken spinal black streak; underparts creamy yellow, tinged with ferruginous on throat and thighs (Ticehurst).

A curious feature of the Woodcock is its abnormally high and backwardly placed eyes, virtually at the back of its head. The exact function of this adaptation needs study.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂♂	186–205	68–79	34–38	71–82 mm.
♀♀	184–208	67–80	—	—
	(one 172)	(from feathers)		(Witherby)

Baker gives ♂♀ Wing 183–219 mm.; weight 7–16 oz. (c. 198–454 gm.). Weight 1 ♀ 335 gm.—BB.

COLOURS OF BARE PARTS. Iris deep brown. Bill horny brown darker at tip, paler, tinged with purple, at base of lower mandible. Legs and feet greenish grey or olive-brown; claws horny brown.

Genus CALIDRIS Merrem

Calidris Anonymous = Merrem, 1804, Allg. Lit. Zeitung 2 (168): col. 542. Type, by tautonymy, *Tringa calidris* Gmelin = *Tringa canutus* Linnaeus

Erolia Vieillot, 1816, Analyse: 55. Type, by monotypy, *Erolia variegata* Vieillot = *Sceloporus testaceus* Pallas

Oreocetes Billberg, 1828, Syn. Faun. Scand. 1(2): 132. Type, by monotypy, *Charadrius calidris* Linnaeus = *Trypa alba* Pallas

Cf. Bis 1949: 509.

Delacour, J., 1951, L'Oiseau, 21: 6.

Bill slender varying a good deal in length, either straight or slightly downcurved; both mandibles grooved. Nostrils linear, placed in a groove at base of upper mandible. Hind toe present in most species; anterior toes unwebbed. Wing long and pointed: first primary (al.) longest. Tail nearly square with the central feathers pointed and projecting slightly beyond the others.

Genus cosmopolitan; represented in India only by Palearctic migrants in winter.

Key to the Species

B Upper tail-coverts grey, dark brown, or similar to back	2
1 Bill long and decurved	<i>C. testacea</i>

294 CHARADRIIFORMES

the Pyrenees, Alps, northern-Balkan States, Kashmir, the Himalayas, Ussuri, and Japan. Winters in the southern part of its range, the Mediterranean region, Egypt, India, Ceylon, S. China, and Japan. Resident on Madeira, the Canary Is., and the Azores (Peters).

MIGRATION (in India). No ringing data. Commences to arrive in the Nilgiris and other S. Indian hills during October; numbers at peak in December-January; mostly gone again by end of March. From striking paucity of records in Peninsular India, probably journey from Himalayas performed in a single non-stop flight. The sporadic records of odd birds, obviously on passage, are from Karachi (W. Pakistan), Bhuj, Mt Abu (Gujarat), Thana near Bombay (Maharashtra), Agra, Muzaffarnagar, Sitapur, Mainpuri, Kanpur (Uttar Pradesh), Golconda (?) and Eastern Ghats [Salabam, Padera] (Andhra), and Madras City. Indications suggest that the birds reach their southern winter quarters mainly by the Eastern Ghats route.

GENERAL HABITS snipe-like. Usually solitary or in separated pairs. Largely crepuscular and nocturnal, lying up in shady cover during daytime, seldom stirring after sunrise or before dusk unless driven. Feeds by probing into soft wet earth with its sensitive-tipped bill, the bird's presence in a glade being revealed by the honeycombed patches left in the ground. Flight rather sluggish and wavering, reminiscent of Painted Snipe, but with unexpected sudden jerks and zigzags this side and that, and swift turns and twists to avoid tree-trunks in its wooded habitat, the bird dropping down abruptly into cover 'as if it had flown against a wall'. Thus, in spite of its large size, the sportsman finds it less difficult to miss the target than would appear possible!

In the breeding season the male (?) performs his characteristic aerial display known as 'roding' at dusk and dawn. This consists of flapping slowly in a high arc back and forth across an open glade or flying round and round over it in wide circles to the accompaniment of a 'loud wailing cry' (B. B. Osmaston) or a deep croak, and sometimes a shrill bat-like squeak, at intervals.

FOOD. Chiefly worms and grubs; occasionally some seeds and shoots.

VOICE and CALLS. Besides the notes uttered while roding, Osmaston has described 'a continuous sort of grating, purring noise' made by a female he disturbed off the nest. 'A strange croaking like a nutcracker's' while occupied in shifting downy chicks from one spot to another (Bates).

BREEDING. Season in the Himalayas, April to July. Nest, a depression in the ground lined with dry leaves, etc., well concealed amongst bracken, dwarf rhododendron or other undergrowth, preferably near a wooded stream. Eggs, 4, pale clay colour to deep buff, boldly blotched with pale reddish brown and grey. Average size of 55 Indian eggs 44.5 × 33.3 mm. (Baker). Fide Witherby incubation and tending of young by female alone; period of incubation 20–21 (22) days. A peculiar habit of Woodcock, also recorded elsewhere in its range and reliably observed and authenticated in the Himalayas (more recently by R. S. P. Bates, JBNHS 43: 69), is its transporting its downy chicks to a place of safety when danger threatens. This is accomplished by carrying them pressed between the parent's thighs and breast and dangling below. With legs thus occupied, parent finds considerable difficulty in

412. Knot. *Calidris canuta canuta* (Linnaeus)

Tringa canutus Linnaeus, 1758, Syst. Nat., ed. 10, 1: 149 (in Europa = Sweden) Baker, FBI 2161a, Vol. 8: 698

Plate 40, fig. 13 and Plate 41, fig. 10

LOCAL NAMES. None recorded.

SIZE. Grey Quail 4; length c. 25 cm. (10 in.).

FIELD CHARACTERS. Rather like Dunlin (420) in winter—scaly (or scalloped) ashy grey above, white below—but larger and stockier, with straight relatively shorter bill and legs. In flight, larger size than Dunlin, pale rump (v. black-centred) and tail, and pale wing-bar are suggestive pointers. In its normal range characterized by keeping in densely packed flocks.

Summer. Above, strongly mottled chestnut and black; below, bright rufous.

STATUS, DISTRIBUTION and HABITAT. Rare vagrant in winter. Obtained within our limits only once in Baluchistan (Khushdil Khan Lake—26 March) by Col. R. Meinertzhagen, presumably on passage, and once in Ceylon (Mannar, 15.xii.1928)—Wait, 1931: 365. Tamil Nadu (Pt Calimere) 2 specimens—JBNHS 67: 282. Normally prefers extensive coastal mudflats and estuaries and is rare inland.

Extratropical. Breeds in Spitzbergen and on the Taimyr Peninsula. Winters in Africa (Peters).

CURLEWS, SANDPIPERS, SNIPE, WOODCOCK 297

GENERAL HABITS, FOOD, VOICE and CALLS. One of the maritime waders. Nothing recorded in our area. For an account see Witherby, 1940, 4: 228-31. **BREEDING.** Extralimital.

MUSEUM DIAGNOSIS. Similar to Eastern Knot (413) but with a much smaller bill. Upper tail-coverts white strongly barred with blackish; spots on underparts larger and less well defined.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂♂	162-171	30-34	27-5-31	50-5-66-5 mm.
♀♀	164-174	31-5-38-5	—	—

(Witherby)

COLOURS OF BARE PARTS. Iris brown. Bill black. Legs and feet olive-green.

413. Eastern Knot. *Calidris tenuirostris* (Horsfield)

Totanus tenuirostris Horsfield, 1821, Trans. Linn. Soc. London 13(1): 192 (Java) Baker, FBI 2162, Vol. 6: 243

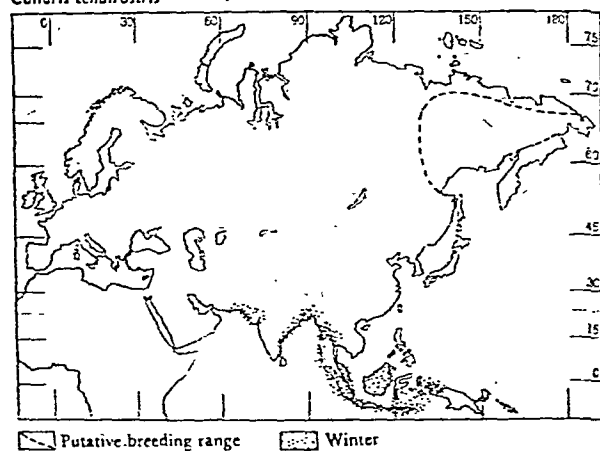

Plate 40, fig. 12 and Plate 41, fig. 11

LOCAL NAMES. None recorded.

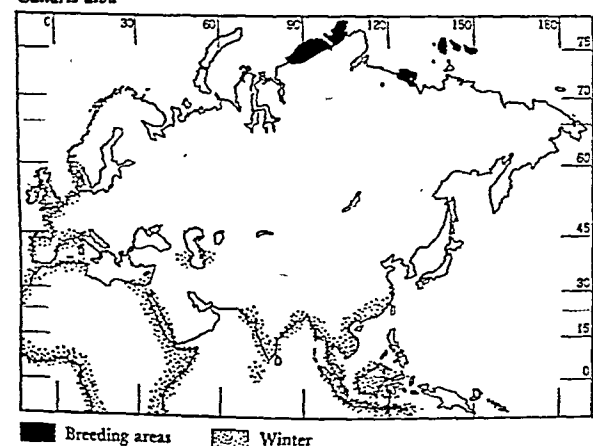

SIZE. Grey Partridge —; length c. 29 cm. (11½ in.).

FIELD CHARACTERS. A stocky shore bird, usually seen in flocks feeding in company with stints and other small waders amongst which it stands out conspicuously by its size. On the wing, in the distance, confusion possible with Bartailed Godwit with which it also often associates.

Adult. Winter. Above, light brownish grey, boldly streaked with black. Lower back, rump and upper tail-coverts dark brown scalloped with

Calidris tenuirostris

CURLEWS, SANDPIPERS, SNIPE, WOODCOCK 299

Calidris alba

mandel and Orissa coasts. Large numbers ('flocks of more than a thousand') between August and February along the seacoast and flooded sand flats in the southern part of Rameswaram I. (Biddulph, JBNHS 40: 234). Regular winter visitor in small flocks to Ceylon (Phillips), and occurs also in the Laccadive and Maldiva Is.

Extralimital. A Holarctic species. In the Palaearctic Region breeds on Spitzbergen and the arctic coasts and islands of Siberia from the Taimyr Peninsula to the mouth of the Lena river. In the Old World winters in the British Isles, the North Sea, India, Malay Archipelago, China, Japan, and Australia. South to S. Africa; and Madagascar.

MIGRATION. No ringing data. Either migrates along the coasts or is capable of immense non-stop transcontinental flights, as has never been recorded inland in our area.

GENERAL HABITS. Feeds in mixed flocks with Dunlins, Curlew-Sandpipers, and other small waders on tidal mudflats or strung out along the edge of the surf on sandy shores. Recognized among the miscellaneous crowd by its whitish coloration and ceaseless activity, running swiftly on a blur of twinkling legs after each receding wave to pick up any titbits it may cast ashore, and hurriedly retreating before the oncoming next. Continues to run back and forth and feed thus when most of its associates are resting at high tide in wait for the ebb. The flocks fly in regimented unison, flashing white from time to time as they bank and wheel.

FOOD. Tiny crustaceans, molluscs and other small animals washed up on the seashore.

VOICE and CALLS. A shrill liquid *wick-wick* when flushed, and occasionally in flight. No other notes recorded in its winter quarters in India.

BREEDING. Extralimital; on arctic tundra.

298

CHARADRIIFORMES

white, much more broadly on the last, making the feathers sometimes almost all white. *Below*, white; foreneck and upper breast streaked or spotted with dark brown. Sexes alike.

Summer. Above, blackish brown scalloped with white; boldly spotted with chestnut on scapulars. Tail-coverts (upper and lower) white, spotted and barred with dark brown. *Below*, densely spotted with blackish brown and without any rufous.

STATUS, DISTRIBUTION and HABITAT. Winter visitor, not abundant but not rare on the Makran, Sind, Kutch and Kathiawar coasts. Also recorded from Assam (Dibrugarh, Cachar), Calcutta, Madras, Andaman and Laccadive Is.; not Ceylon. Possibly occurs in Bangladesh as it does in Burma. Affects tidal mudflats and creeks on the sea coast. In inland localities probably on migration.

Extralimital. Breeding range not properly known; believed to be chiefly NE. Siberia. Actual breeding records from mountains near lower Kolyma river and in Anadyrland and Koryakland. (For details see Vaurie, C., 1965, 2: 403.) On migration in China and Japan. Winters chiefly in the Malay Archipelago, Moluccas, and Australia.

GENERAL HABITS, FOOD, VOICE and CALLS. Nothing recorded as different from other shore waders.

BREEDING. Extralimital and little known.

MUSEUM DIAGNOSIS. See Key; for details of plumage see Baker, loc. cit.

MEASUREMENTS

COLOURS OF BARE PARTS. Iris dark brown. Bill dusky black. Legs and feet greenish dusky (Armstrong).

414. Sanderling. *Calidris alba* (Pallas)

Tyrna (alba) Pallas, 1764, in Vroeg's Cat. Adumbr.: 7 (Coast of the North Sea)

Baker, FBI No. 2153, Vol. 6: 231

Plate 40, fig. 19 and Plate 41, fig. 5

LOCAL NAMES. None recorded.

SIZE. Grey Quail —; length c. 19 cm. (7½ in.).

FIELD CHARACTERS. A plump little shore bird, slightly larger than Dunlin (420), with slender *straight* bill. Most readily recognized in winter among other small coastal waders by its overall pale (almost whitish) coloration and blackish shoulder-patch; also by its extreme activity, chasing waves back and forth on the seashore for washed-up food. Identified in flight by whitish plumage and the very conspicuous white wing-bar.

Summer. Above, chestnut mottled with black; below, pure white. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Winter visitor. Abundant on the coastline of W. Pakistan (Makran, Sind). Less common than Little Stint and Dunlin on the western seaboard of India; rare on Kerala coast. On the eastern side tolerably abundant around Pt Calimere and along the Coro-

COLOURS OF BARE PARTS. Iris brown. Bill black. Legs and feet olive-green or yellowish olive.

418. Longtoed Stint. *Calidris subminata* (Middendorff)

Tringa subminata Middendorff, 1853, Reise Nord. und Ost. Siberien 2, Th. 2: 222, pl. 19, f. 6 (Western slopes of the Stanovoi Mountains and mouth of the Uda)
Baker, FBI No. 2157, Vol. 6: 236
Plate 40, fig. 10

LOCAL NAMES. None recorded.

SIZE. Same as Little Stint: House Sparrow +; length c. 15 cm. (6 in.).

FIELD CHARACTERS. A diminutive wader, very like Little Stint (416), also with outer tail-feathers greyish brown (v. white in Temminck's) and not distinguishable from it with certainty unless in the hand (see Museum Diagnosis). In winter very dark almost black crown and much darker mottlings on the back are usually suggestive pointers. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Winter visitor. Specimens collected in Nepal, Assam, Bangladesh, Bihar, Andaman Is., Ceylon and Maldivic Is. Probably regular and less uncommon than supposed, but overlooked due to difficulty in field discrimination from Little Stint. Around 1878 Hume found the two to be brought in about equal number to the Calcutta bird market. However, of birds caught recently in N. Bihar for ringing, the proportion was 34 Little Stints: 109 Temminck's: 2 Longtoed (P. V. George, JBNHS 62: 302).

CURLEWS, SANDPIPERS, SNIPE, WOODCOCK 307

419. Asian Pectoral or Sharptailed Sandpiper. *Calidris acuminata* (Horsfield)

Totanus acuminatus Horsfield, 1821, Trans. Linn. Soc. London 13(1): 192 (Java)
Baker, FBI No. 2159, Vol. 6: 239
Plate 40, fig. 11

LOCAL NAMES. None recorded.

SIZE. Grey Quail ±; length c. 22 cm. (8½ in.).

FIELD CHARACTERS. Resembles Little Stint and Dunlin but is somewhat larger. In winter chin, throat, and abdomen white; foreneck and breast pale brownish grey with small dark streaks or spots. On a good view, in flight, the pointed white-edged tail-feathers should be suggestive.

Summer plumage much darker; upper breast tinged with rufous; dark spots on breast broader, often taking the form of angulate bars, extending to the flanks. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Rare vagrant in winter. Recorded by Col. A. E. Ward in 1907 as 'a very rare visitor' to Kashmir (JBNHS 17: 946) but not found there since. J. Biddulph shot a specimen in Gilgit on 1 August, 1880 (SF 10: 276) and W. W. A. Phillips one in Ceylon more recently — 18 September 1955 (SZ 28(2): 183). These are the only records within our limits. It is possible that some are lost for want of critical examination.

Extralimital. 'Breeds on the Chukchi Peninsula [NE. Siberia]. Migrates through E. Asia; winters in the eastern part of the Malay Archipelago, New Guinea, Australia, and some of the S. Pacific islands' (Peters).

GENERAL HABITS, FOOD, VOICE and CALLS. The Gilgit specimen was flying about with a number of Ruff (*Philomachus pugnax*). The Ceylon example was feeding with Curlew-Sandpipers (*Calidris testacea*), Wood and Marsh Sandpipers (*Tringa glareola* and *T. stagnatilis*), Terek Sandpipers (*T. terek*) and Broadbilled Sandpipers (*Limicola falcinellus*) in shallow water in the bed of a coastal lagoon.

BREEDING. Extralimital.

MUSEUM DIAGNOSIS. In the hand the best point of distinction is the tail-feathers, all of which are pointed or acuminate in this species, whereas in the rather similar Dunlin (420) only the central ones are pointed. The latter, moreover, has a slightly downcurved bill. For description of plumage see Baker, loc. cit.; for details of plumage phases and morphology (also bionomics), Witherby, 1940, 4: 263-5.

MEASUREMENTS

♀♀	124-133	23-29	—	—
				(Witherby)

The Ceylon specimen (♀) measured
124 25 29 50 mm.
Middle toe with claw 28 mm. (Phillips)
COLOURS OF BARE PARTS. Iris dark brown. Bill black, base below brownish. Feet (ad.) dull greenish-grey, (juv.) dirty greyish ochraceous (Witherby).
'Iris dark brown; eyelids greyish white; bill dark greenish lead with the lower mandible lighter towards the base; legs and feet bright green with a yellowish tinge' (Phillips).

306 CHARADRIIFORMES

Calidris subminata

■ Breeding areas ▨ Imperfectly known and putative breeding range
▨ Winter

Extralimital. 'Breeds in E. Siberia south to Kamchatka and on the Commander and Kurile Is., perhaps also on Sakhalin. Migrates through China and Japan and winters in E. India, Burma, Malay Peninsula, Sunda Is., and the Philippines' (Peters).

MIGRATION. No ringing or other specific data.

GENERAL HABITS, FOOD, VOICE and CALLS. Keeps in mixed flocks with Little and Temminck's Stints on inland marshes as well as tidal mudflats. Nothing recorded as different from the other stints.

BREEDING. Extralimital.

MUSEUM DIAGNOSIS. Upperparts darker than in *C. minuta* in winter due to the dark centres of the feathers covering a larger area; tail-feathers darker brown; a well-defined grey-streaked pectoral gorget. Toes noticeably longer and slenderer: middle toe 22-25 mm. (c. under 20 mm. in the other two stints). Middle toe with claw longer than tarsus (c. more or less equal); hind toe longer — 5 to 6 mm. c. 3 to 4 mm. For description of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂♀	87-95	17-19	c. 20-21	34-36 mm. (Baker)

Weight 17 ♂♀ (autumn/winter) 16-23 (av. 19.9) gm. — BNHS.

COLOURS OF BARE PARTS. 'Iris brown. Bill olive-brown to blackish, paler at the base of the lower mandible. Legs and feet pale olive-yellow to pale brown' (Baker).

308 CHARADRIIFORMES

420, 421. Dunlin. *Calidris alpina alpina* (Linnaeus)

Tringa alpina Linnaeus, 1758, Syst. Nat., ed. 10, 1: 149 (Lapland)
Erolia alpina centralis Buturlin, 1932, Alauda (2), 4: 265 (Yakutsk, eastern Siberia)
Baker, FBI No. 2161, Vol. 6: 241
Plate 40, fig. 14 and Plate 41, fig. 6

LOCAL NAMES. Not recorded.

SIZE. Grey Quail —; length c. 19 cm. (7½ in.).

FIELD CHARACTERS. Essentially maritime. In winter confusingly like Curlew-Sandpiper (422) but with the bill slightly less downcurved near the end: above, greyish brown with a good deal of fine dark mottling; below, white, with a diffuse greyish-streaked band across breast. Sexes alike.

In flight the whitish wing-bar, as in Curlew-Sandpiper, conspicuous; differentiated from it with certainty only by the blackish (contra white) upper

tail-coverts. At rest among a mixed flock of small waders, characteristic rounded or 'hunched-up' profile suggestive of Dunlin.

Summer plumage diagnostic: above, chiefly black, boldly scalloped with bright deep rufous or chestnut; below, white, with centre of breast and abdomen black. Remnants of this plumage frequently seen among the earlier immigrants in autumn; fresh summer plumage donned partially or fully before departure in April and May.

STATUS, DISTRIBUTION and HABITAT. Common and abundant winter visitor to the seaboard of West Pakistan (Makran and Sind coasts) and NW. India (Kutch, Saurashtra — Gujarat). Sparsely inland, as occasional winter visitor or passage migrant, throughout northern and peninsular India from Kashmir to Kerala, and east to Assam; also both Pakistans, and Nepal. Uncommon east of Bihar, and a straggler south of central coastal Maharashtra and the Deccan. Not recorded in Ceylon or Andaman Is. though specimens have been collected in the Maldives where it is 'probably a regular winter visitor in small numbers' (Phillips, JBNHS 60: 575). Affects the seashore, tidal mudflats and creeks, river banks, flooded fields, etc. in association with other waders.

CURLEWS, SANDPIPERS, SNIFE, WOODCOCK 309

Calidris alpina

■ Breeding range ■ Winter 1 *C. a. alpina* (420).
2 *C. a. schinzii* (RE). 3 *C. a. centralis* (421). 4 *C. a. sakhalina* (RE).

Extralimital. 'Breeds in Iceland, the Faeroes, and in Europe and Asia from N. Scandinavia to the Yamal Peninsula; Kolguev and Vaigach Is., northern Nova Zemlya and Spitzbergen; southern breeding limits south to Pskov, the upper Volga and the lower Ob. Winters in the Mediterranean region, NE. Africa and SW. Asia' (Peters).

MIGRATION. No ringing data. Adults in worn breeding dress arrive in W. Pakistan (Karachi harbour) [also on the Gujarat coast] in the first days of August; young birds later. The majority depart in the second or third week of May (latest 5 June). Odd birds overwinter, unlike most waders, in summer dress (Ticehurst, *Riv* 1924: 111).

GENERAL HABITS. Keeps in flocks, often mixed with Curlew-Sandpipers, stints, sand plovers and other small waders. The birds scatter to feed on the seashore or mudflats at low tide, running about and probing with their bills into the soft mud. On alarm the flock rises more or less simultaneously and flies off in packed formation — the different species sometimes breaking up into smaller bands of their own — turning, twisting and banking in the air at great speed, their white underwings flashing in the distance from time to time. At high water the feverish activity slackens; the birds bunch-up on dry ground waiting for the ebb to resume feeding.

FOOD. Molluscs, crustaceans, worms, sandhoppers, chironomid larvae and other insects; occasionally some seeds. A large quantity of gritty sand commonly found in stomachs, together with brownish mucous-like matter.

VOICE AND CALLS. Ordinary call in winter a prolonged rather shrill *tut-tut* or *tee-tee-tee* especially when taking wing. A soft purring sound produced by a flock while feeding or alighting has been described. In breeding

* See Appendix

CURLEWS, SANDPIPERS, SNIFE, WOODCOCK 311

good deal of fine dark mottling; below, white, with the breast streaked and washed with brown. When at rest or feeding in a mixed flock with Dunlin its slightly larger size, longer legs, and similarly downcurved but somewhat slenderer bill are suggestive pointers. In flight differentiated from Dunlin with certainty only by its *white* (contra blackish) upper tail-coverts.

Tail, x c. 1

Summer plumage completely different from Dunlin's and diagnostic: mainly chestnut and rich rufous, above and below. As in Dunlin remnants of this plumage commonly seen among the earlier immigrants in autumn. Most birds have moulted back into the chestnut dress before departure for the breeding grounds in spring.

STATUS, DISTRIBUTION AND HABITAT. Common winter visitor to the entire seaboard of West Pakistan and India. Doubtless also in East Pakistan since it occurs in the Sunderbans of W. Bengal. Also Ceylon, the Maldives, Andaman, and Nicobar Is. In small numbers inland — as winter visitor and/or passage migrant. Not recorded in Nepal. Affects the seashore, tidal mudflats and creeks, salt-pans, squelchy paddyfields and marshes, etc. in association with other waders.

Extralimital. 'Breeds in N. Asia at the mouth of the Yenisey, in W. Taimyr, Cape Bolshoi Baranov and on the New Siberian Is. On migration occurs throughout Europe and Asia; winters in Africa, Madagascar, India, Burma, Malay Archipelago, and Australia' (Peters).

MIGRATION. No ringing data. Adults in worn breeding dress, often still in pairs, arrive on the Makran, Sind, and Gujarat coasts as early as the last days of July or first week in August; juveniles (according to Ticehurst) in the first days of September. Most birds have departed by end April; many in full breeding dress linger on till c. mid May accumulating enormous quantities of body fat; yet others (in non-breeding plumage) overwinter on our shores.

GENERAL HABITS AND FOOD. Similar to Dunlin, q.v. Keeps in large flocks often of several hundred strong, usually mixed with stints, dunlins, sand plovers, and other waders.

VOICE AND CALLS. Not authentically recorded in India, the fact of its keeping in mixed flocks making it difficult to isolate the calls of the various

* See Appendix

CHARADRIIFORMES

season male delivers a rich trilling song in fluttering switchback flight, or from an exposed perch, over or near the nesting place.

BREEDING. Extralimital. Season, June-July. Nest, a neat cup at base of grass tussock on damp ground, near water. Eggs, 4.

MUSEUM DIAGNOSIS. See Key. For description of plumage Baker, loc. cit.; for details of structure (and bionomics) Witherby 1940, 4: 232-40.

MOUL. 'Spring moult begins early in April, and by the third week is well on; it involves most of the body feathers, not the wings and as a rule not the tail. As in most waders the males are always in advance of the females' (Ticehurst).

MEASUREMENTS of birds collected in our area in winter:

	Wing	Bill (from feathers)	Tarsus	Tail
Sind 22 ♂♂	112-121	29-36	24-27	— mm.
18 ♀♀	116-123	34-39	25-27	— mm.
		(from skull)		(Ticehurst)
Gujarat 2 ♀♀	120-124	40-41	26-28	47-53 mm. (SA)

Weight 20 ♂♀ (autumn/winter) 34-57 (av. 44.1) gm. — BNHS.

COLOURS OF BARE PARTS. Iris hazel or dark brown. Bill, legs, and feet black.

It is possible that some of the dunlins wintering in eastern India may belong to the race *Calidris alpina centralis* Butorlin (421), described as having more white on the outer webs of the inner primaries. However, *centralis* is an intermediate (clinal) form between the nominate western race *alpina* and the somewhat larger eastern *C. a. sakhalina* (Vieillot). In winter plumage *sakhalina* itself is doubtfully separable from *alpina* though the reduction in its breast streaking is evidently discernible and the outer webs of the inner primaries are somewhat more broadly bordered with white on an average. *C. a. sakhalina* breeds in NE. Siberia and it is likely that the birds wintering in Assam, E. Pakistan, and Bengal belong to that race, or approaching it ('*centralis*'), though in winter plumage allocation with certainty is impossible.

Hartert (Vög. pal. Fauna: 1577) gives the measurements of *sakhalina* as:

Wing ♂♂ 177-123, rarely 125, mostly 119-121 mm.; ♀♀ 120-126, exceptionally up to 130 mm. Bill (from feathers) ♂♂ 31.3-35.8; ♀♀ 34-42 mm. Tarsus ♂♂ 25-27.5; ♀♀ 25-28 (29) mm.

422. Curlew-Sandpiper. *Calidris testacea* (Pallas)

Scolopax testacea Pallas, 1764, in Vroeg's Cat. Adumbr.: 5 (Holland)
Baker, FBI No. 2160, Vol. 6: 240

Plate 40, fig. 15 and Plate 41, fig. 7

LOCAL NAMES. None recorded.

SIZE. Dunlin \pm ; length c. 20 cm. (8 in.).

FIELD CHARACTERS. An essentially maritime species. In winter very like Dunlin (420) and easily confused with it: above, greyish brown with a

x c. 1

CHARADRIIFORMES

Calidris testacea

■ Breeding range ■ Winter

species. According to Baker 'in winter it has a twittering call as well as a rather shrill single note'.

BREEDING. Extralimital. More or less similar to Dunlin.

MUSEUM DIAGNOSIS. Somewhat larger size (cf. Measurements) and white upper tail-coverts distinguish it from the very similar Dunlin in winter. The breeding plumages of the two are diagnostic (see Field Characters); for detailed description see Baker, loc. cit., and Witherby, 1940, 4: 242-4.

MOUL. In adults, moult of body feathers from the worn breeding plumage commences about the first week in August. Spring moult takes place in March and April and by mid April is well advanced. Most birds have acquired full summer dress by the third week of April (Ticehurst).

MEASUREMENTS of birds collected in our area in winter:

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	124-137	37-44	28-31	43-52 mm.
♀♀	130-134	41-45	30-32	47-52 mm. (CBT, HW, SA)

Weight 20 ♂♀ (winter) 36-53 (av. 45.5) gm. — BNHS.

COLOURS OF BARE PARTS. Iris brown. Bill black. Legs and feet greyish plumbeous to black.

Genus EURYNORHYNCHUS Nilson

Euryrhynchus Nilson, 1821, Orn. Svecica 2: 29. Type, by monotypy, *Euryrhynchus griseus* Nilson = *Platyleia pygmaea* Linnaeus

Genus unique and readily distinguished from all others by the remarkable shape of the bill which terminates in a flat quadrilateral disc or spatula, bluntly angulate at each side and at the end. Basal portion of bill depressed throughout with bright

CURLEWS, SANDPIPERS, SNIPE, WOODCOCK 313

and breadth about equal. Nostrils small and placed quite at the base. Other characters as in *Calidris*, q.v.

Contains a single eastern Palearctic species.

423. Spoonbilled Sandpiper. *Eurynorhynchus pygmaeus* (Linnaeus)

Platalia pygmaea Linnaeus, 1758, Syst. Nat., ed. 10, 1: 140

(in Surinami = eastern Asia)

Baker, FBI No. 2154, Vol. 6: 232

Plate 40, fig. 18

LOCAL NAMES. None recorded.

SIZE. Little Stint ±; length c. 17 cm. (6½ in.).

FIELD CHARACTERS. A small stint-like wader with a unique spatula-shaped bill. Winter plumage largely white, with dark-shafted pale greyish brown upperparts (including crown). Rump and upper tail-coverts dark brown in the middle, white at the sides. Middle rectrices dark brown, outer rectrices paler, with white edges and shaft-stripes.

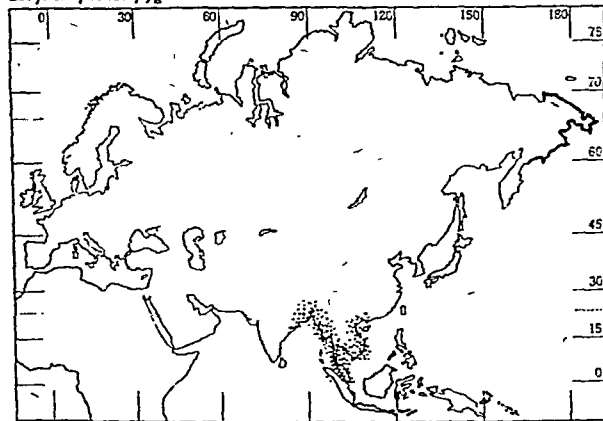

x c. 1

Summer (breeding). Above, blackish, the feathers fringed with rufous. Below, foreneck and breast deep ferruginous spotted with dark brown; rest white.

STATUS, DISTRIBUTION AND HABITAT. Very rare winter visitor to West Bengal, Assam, and East Pakistan. Up till Jerdon's time, c. 1864, it had only been recorded at the mouths of the Ganges [Sunderbans] and on the coast of Chittagong. Hume only found a single example brought to the Calcutta bird market in the course of his frequent visits there over several years (c. 1877). Since then Baker records two obtained in the Sibsagar district

Eurynorhynchus pygmaeus

■ Breeding range □ Winter

CURLEWS, SANDPIPERS, SNIPE, WOODCOCK 315

424. Broadbilled Sandpiper. *Limicola falcinellus falcinellus* (Pontoppidan)

Scolopax Falcinellus Pontoppidan, 1763, Dansk. Atlas 1: 623, pl. 25 (No locality, Sialandia ex Orn. Boreal.: 49 = Denmark)

Baker, FBI No. 2163, Vol. 6: 245

Plate 40, fig. 16

LOCAL NAMES. None recorded.

SIZE. Grey Quail ±; length c. 17 cm. (6½ in.).

FIELD CHARACTERS. Very like Dunlin (420) and Curlew-Sandpiper (422) with similar slightly downcurved bill, and confusable with both. In winter above, dark-mottled greyish brown; below, white, sparsely streaked on breast. Rump, upper tail-coverts and middle rectrices brown as in Dunlin from which doubtfully distinguishable in flight. At rest the long whitish supercilium (not meeting across forehead), and blackish patch on wing-shoulder are suggestive pointers. On a fairly close view the somewhat smaller size, shorter legs and more marked spotting of the cheeks and breast help further to distinguish it from Dunlin.

In summer (breeding plumage) a smaller but passable replica in coloration and pattern of the Jack Snipe (410), q.v. This dress donned before departure in May, the birds then looking nearly black on the ground and unmistakable even at a distance.

STATUS, DISTRIBUTION AND HABITAT. Winter visitor to the seaboard of both Pakistans, India, Ceylon, Andaman, and Nicobar Is. Common on the Makran and Sind coasts. Perhaps commoner than the records suggest owing to ambiguity in field identification. Recorded less commonly from inland localities in Baluchistan, Delhi, Bihar, and elsewhere — presumably on passage. Affects the coastline, tidal mudflats, muddy creeks and brackish lagoons, and sandbanks in large rivers.

Extralimital. 'Breeds in Norway, Sweden, Lapland, Finland, N. Russia and Siberia east to the Yenisey and perhaps further, exact northern and southern limits not known, but not extending into the tundra; breeds also in Orenburg (Ilek River), in Turgai (upper Irgiz) and in the forest steppe of Minusinsk. Winters south to the Mediterranean, Black, Caspian, and Red Seas, Persian Gulf and western India' (Peters).

MIGRATION. No ringing data. According to C. B. Ticehurst (*Ibis* 1924: 116) adults in worn breeding dress arrive on the Sind coast in the last days of July, their numbers increasing in the first week of August. At first they are usually in pairs, the female still showing remains of incubation patches. Immature birds arrive about a month later, in the last week of August or the first in September, and join up with flocks of other waders. In early May most birds have donned breeding dress, segregated out in pure flocks, and become very fat. By the third week of May most have emigrated, leaving a few non-breeding birds behind to overwinter. On the Coromandel coast the influx is heaviest Sept./Oct.

GENERAL HABITS. Not appreciably different from other sandpipers and stints. An impression that needs confirming is that this species obtains its

¹ The races are inseparable in winter plumage, and the visitors to coastal W. Bengal and E. Pakistan may belong to the eastern race, *sibirica* (425). Specimens taken in Ceylon have however, been confirmed as of the nominate race.

of Assam by a Mr Edens, and one by himself in the Meghna Sunderbans (E. Pakistan). No specimens appear to have been taken within our limits during the last 50 years or so, but one sight-recorded in Sri Lanka (Bundala), Jan. 1978 (CBCN, Feb. 1978: 7). It is rare also in Burma in winter, but apparently less infrequent.

Extralimital. 'Coast of NE. Siberia, west to Vankarem Bay on the north coast of the Chukotski Peninsula and south to southern Koryakland (to Korfa Bay, 166°E. long.). Migrates through the Kuriles, Sakhalin, Japan, Korea, and along the coast of China to winter from S. China to Hainan and the Indochinese countries, and rarely to Assam and Bengal; has wandered to NW. Alaska' (Vaurie).

GENERAL HABITS, FOOD, VOICE AND CALLS. Has been found individually or very sparsely in large mixed flocks of stints and other small waders amongst which it tends to get overlooked. Runs about and feeds with them, and like them, on tidal mudflats etc. The stomach of the specimen shot by Baker contained minute red crabs 'The only note it uttered was a shrill wheel, wheel as it rose.'

[For a very full account of the morphology, bionomics, and breeding biology of the Spoonbilled Sandpiper in NE. Siberia see Portenko, A. L., 1957, *Journal für Ornithologie*, 98(4): 454-66.]

BREEDING. Extralimital.

MUSEUM DIAGNOSIS. See under Genus; for details of plumage Baker, loc. cit.

MEASUREMENTS	Wing	Bill (from feathers)	Tarsus
14 ♂♂ ad.	95.3-102.4 (av. 98.9)	19.6-22.3 (av. 21.2)	20.1-21.8 mm. (av. 20.9)
9 ♀♀ ad.	95.5-103.5 (av. 99.9)	21.7-24 (av. 22.8)	20.4-22.4 mm. (av. 21.6)
Breadth of 'spoon':	13 ♂♂ ad. 8 ♀♀ ad.	10.1-11.2 10.7-11.6	(av. 10.7) mm. (av. 11.1) mm. (Portenko)

Tail: 3 ♂♂ 37-39 mm. (Hartert).

COLOURS OF BARE PARTS. Iris dark brown. Bill, legs, and feet black.

Genus LIMICOLA Koch

Limicola Koch, 1816, Syst. baier. Zool.: 316. Type, by monotypy, *Numenius pygmaeus* Bechstein (not of Latham) = *Scolopax falcinellus* Pontoppidan

Differs from *Calidris* in its bill, which is soft and flexible (with hard tip), slightly downcurved near end, swollen at base and depressed and broad. Nostrils small, placed in a groove near base. Tail short and nearly square, the central rectrices a little longer and pointed. Wing long and pointed, with first primary (as.) longest. Tarsus and toes as in *Calidris*; hind toe well developed.

The genus contains a single Palearctic species.

LIMICOLA FALCINELLUS (Pontoppidan)

Key to the Subspecies

- Upperparts less brightly coloured rufous in breeding plumage..... *L. f. falcinellus*
- Upperparts more brightly coloured rufous in breeding plumage..... *L. f. sibirica*

Limicola falcinellus

■ Breeding range □ Winter 1 *L. f. falcinellus* (424).
2 *L. f. sibirica* (425).

food by 'picking' from the surface like Common Sandpiper, and not by probing its bill into the soft mud like Dunlin or Snipe.

FOOD. Molluscs, worms, tiny gastropods, and insects; also a small quantity of seeds.

VOICE AND CALLS. A twittering flushing note, similar to Temminck's Stint's, is the only call recorded in winter. On its breeding grounds a harsh trill also rather similar to that of Temminck's Stint.

BREEDING. Extralimital.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.; for description of plumage phases and morphology (also bionomics), Witherby, 1910, 4: 290-3. Molt from worn breeding dress into winter plumage (body moult) begins on arrival in winter quarters about first week in August; in immature birds (of the year) about a month later. Towards end February moult into breeding plumage again commences; it is well advanced by early April, and nearly complete by the end of that month. Exodus starts in early May; by the third week most birds have departed (Ticehurst).

MEASUREMENTS	Wing	Bill (from feathers)	Tarsus	Tail
♂♀	101-113	30-36	20-23	35-42 mm.

Weight 25 ♂♂ (autumn/winter) 26-40 (av. 32.25) gm. — BNHS.

COLOURS OF BARE PARTS. Iris dark brown. Bill horny black or brown, strongly tinged with olive-green. Legs very dark lead (ad.); dark yellowish olive (juv.).

CURLEWS; SANDPIPERS, SNIPE, WOODCOCK 317

425. **Eastern Broadbilled Sandpiper.** *Limicola falcinellus sibirica* Dresser
Limicola sibirica Dresser, 1876, Proc. Zool. Soc. London: 674 (Siberia and China)
Baker, FBI No. 2164, Vol. 6: 246

LOCAL NAMES. None recorded.
SIZE. Same as 424; c. 17 cm. (6½ in.).
FIELD CHARACTERS. In winter plumage indistinguishable from 424, q.v. Summer (breeding). More rufous and spotted and streaked than 424. See Museum Diagnosis.
STATUS, DISTRIBUTION and HABITAT. Winter visitor to the seaboard of W. Bengal and East Pakistan as it is commonly in Burma. Owing to difficulty of identifying the races in winter plumage, the range of *sibirica* within our area is somewhat obscure.

Extralimital. 'Breeding range unknown but presumably N. Siberia east of the Yenisey. Winters from Formosa (rarely) and SE. China (a few), and Hainan, south to the Indochinese countries, coast of eastern India, and Sundas to Australia' (Vaurie).
GENERAL HABITS, FOOD, VOICE and CALLS. Same as 424.
BREEDING: Extralimital.

MUSEUM DIAGNOSIS. In summer plumage differs from nominate race (424) in having the upperparts much more rufous, each feather boldly spotted and streaked with bright rufous.

MEASUREMENTS and COLOURS OF BARE PARTS. Same as 424.

Genus TRYNGITES Cabanis

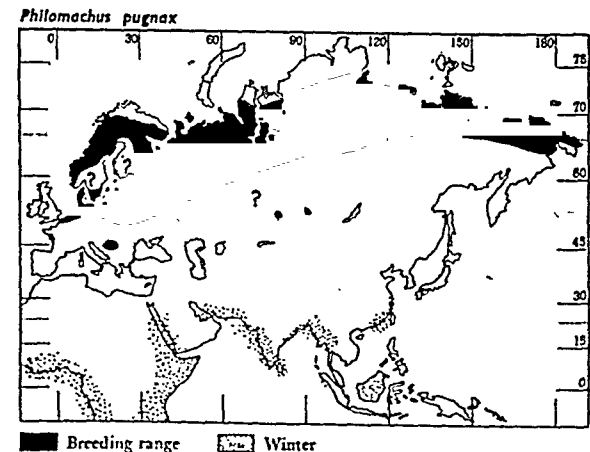

Tryngites Cabanis, 1856 (1857), Jour. f. Orn. 4: 418. Type, by original designation, *Tringa rufescens* Vieillot = *Tringa subruficollis* Vieillot
Very close to *Calidris*. Easily recognized by small black spots on inner webs of primaries. Bill much longer than tarsus, straight, hard, not flexible. Sides of tail not emarginated; middle rectrices much longer than rest. Male larger than female. Summer and winter plumages more or less alike.
Contains a single Palaearctic species.

425a. **Buffbreasted Sandpiper.** *Tryngites subruficollis* (Vieillot)
Tringa subruficollis Vieillot, 1819, Nouv. Dict. Hist. Nat. 34: 465 (Paraguay)
Not in Baker, FBI

SIZE. Common Sandpiper ±; length ♀ c. 18 cm., ♂ c. 20 cm. (7-8 in.).
FIELD CHARACTERS. Stockier than Common Sandpiper with shorter bill and noticeably rounded head. Above, blackish with the feathers prominently bordered with buff ('scalloped') like Ruff in winter plumage. Rump uniformly dark-coloured without contrasting pattern. Below, buff, including throat and sides of face. Sexes alike.
Frequents upland fields (dry open ground) as well as scashores.
STATUS, DISTRIBUTION and HABITAT. Accidental vagrant. A solitary specimen collected in Ceylon at Kalametiya Lagoon on 5.iii.1960 (*Loris* 8(5): 330-1); another sight-recorded Trincomalee, Nov. 1974 (CBCN).
Extralimital. 'Breeds on the arctic coast of N. America from Alaska to Mackenzie. Migrates chiefly through the interior of N. and S. America

CURLEWS, SANDPIPERS, SNIPE, WOODCOCK 319

confused with Redshanks in distance. In flight a narrow white wing-bar, the dark rump and tail with a white patch on either side at its base, are suggestive pointers.
In summer plumage, Ruff (♂) extremely variable with much black, white, purple, chestnut, and buff in plumage, and with a peculiar erectile shield-like ruff and ear-tufts of stiff, curled feathers. Face bare, covered with small fleshy papillae of bright yellow or pale pink. Remnants of breeding plumage occasionally seen on arrival in India. Reeve (♀) as in winter, but blacker above, and sometimes with black linear spots or broken bars on pale fulvous breast — reminiscent of pattern in bustard-quail.
STATUS, DISTRIBUTION and HABITAT. Winter visitor to both Pakistans and all India including Kashmir, Nepal, Assam and Manipur. Also Ceylon and Maldives Is. In some areas (e.g. Nepal) merely an autumn and/or spring passage migrant, in others (e.g. Sind) partly winter visitor and partly passage migrant. Curiously not recorded from the Andaman and Nicobar Is.

Affects tidal mudflats and estuaries, and inundation marshes, and squelchy or wet paddy stubbles and fallows inland.
Extralimital. 'Breeds in N. Europe and Asia from Nordkapp east across the tundra to the Kolyma (including Kolguev and Vaigach Is.) south to eastern England (formerly), Belgium, Bavaria, Hungary, steppes of S. Russia and W. Siberia (north of lat. 50°N.), Minusinsk, and the upper Amur. Winters in Africa south to Cape Province, India, Assam, and Burma, rarely to China' (Peters). Has occurred casually on the eastern Atlantic islands, N. America, and the Lesser Antilles. For greater details of distribution see Vaurie, 1965, 2: 405-6.

318 CHARADRIIFORMES

and winters in some part of southern Argentina, but winter concentration area not known' (Peters). Occasionally wanders into the Palaearctic Region.
MUSEUM DIAGNOSIS. Distinguished by pink-buff underparts and by inner webs of primaries and secondaries being freckled with black, and short, slender bill. For description of structure, plumage phases, etc. see Witherby, 1940, 4: 287-90.

MEASUREMENTS	Wing	Bill (from feathers)	Tarsus	Tail
♂♂	129-138	20-23	29-33	54-60 mm.
♀♀	124-129	18-21	—	—

(Witherby)
COLOURS OF BARE PARTS. Iris dark brown. Bill black. Legs and feet dull orange.

Genus PHILOMACHUS Merrem

Philomachus Anonymous = Merrem, 1804, Allg. Lit. Zeitung 2(168): col. 342
Type, by monotypy, *Tringa pugnax* Linnaeus
Bill moderately long, straight, flexible; both mandibles grooved over the greater part of their length. Nostrils linear placed in the groove close to base of upper mandible. Wing long and pointed; first primary (as.) longest; inner secondaries lengthened. Tail rather short and rounded; tail-coverts very long. Tarsus longer than bill from gape, with transverse shields in front and behind. Hind toe moderate; outer and middle toe connected by a web; web between inner and middle toe obsolete.
Male promiscuously polygynous (?) and considerably larger than female. In breeding season he assumes a ruff of long feathers extending from nape down each side of neck and showing extraordinary variation in colour, transforming his appearance completely.
The genus contains a single Palaearctic species.

426. **Ruff.** *Philomachus pugnax* (Linnaeus)
Tringa Pugnax Linnaeus, 1758, Syst. Nat., ed. 10, 1: 148
(in Europa minus boreali = Southern Sweden)
Baker, FBI No. 2152, Vol. 6: 228
Plate 43, fig. 12 and Plate 44, fig. 15

LOCAL NAMES. *Gehwala*, *Bāghdd* (Hindi); *Gowala* (Bengal).
SIZE. ♂ (Ruff) c. Grey Partridge, ♀ (Reeve) Grey Quail +; length ♂ c. 31 cm. (12 in.), ♀ c. 25 cm. (10 in.).
FIELD CHARACTERS. In winter plumage a rather dumpy greyish brown wader with bold blackish scaly-patterned upperparts and relatively short sandpiper-like bill. Red-legged birds on the ground liable to be

Winter, x c. 1

320 CHARADRIIFORMES

MIGRATION. Arrives in West Pakistan (Sind) and NW. India (Kutch, Saurashtra, Rajasthan) in first week August (some as early as the last days of July), but autumn passage in bulk most general in September. Return migration commences in the last days of February and early March, the males going in advance of the females. By mid April the majority have departed, but odd birds linger on till May. Recoveries of ruffs ringed in the Bharatpur area of Rajasthan (c. 27°N., 77°E.) soon after the mass arrivals in autumn (September/October) indicate an interesting trend of dispersal in the succeeding winter months. The movement hence is evidently in an ESE. direction, through Uttar Pradesh, Bihar and W. Bengal to East Pakistan, our farthest recovery in that direction being from Jessore district (c. 23°N., 89°30'E.) — about 1250 km. distant from the place of ringing. All recoveries in spring (March/April) have been in a NW. to N. direction in West Pakistan and beyond, the extralimital ones being in the territories of the U.S.S.R. between c. 60° and 90° E. long. Our northernmost record so far is from the neighbourhood of Norilsk (c. 69°20'N., 88°13'E.) in the Krasnoyarsk region of W. Siberia — a straight-line map distance of some 5000 km. This bird was recovered on 8 June when presumably on its breeding grounds.
GENERAL HABITS. Gregarious; often in company with other waders in parties of 5 to 8 or flocks up to 25 individuals or so. Enormous concentrations of many thousands commonly collect in favourite feeding localities (e.g. the inundated fallows in Bharatpur, Rajasthan) on their first arrival in NW. India and before dispersing in smaller bands over the country. The expansive mudflats at the mouth of the Banas river in the Little Rann of Kutch is the scene of similar colossal aggregations prior to the northward migration in March. The tens of thousands of Ruff that gather here, along with densely crowded 'acres' of other waders, present a spectacle that is truly phenomenal. Jostling flocks feed energetically in wet grass fields or inundated stubbles, picking up grass and weed seeds from the dry surface or probing for food in the squelchy mud with the bill thrust in up to the forehead and chin, sometimes with the head completely submerged. The birds 'hedge-hop' from field to field in close-packed rabbies; when pitching, the body axis is tilted to the vertical and the wings flapped rapidly in a vibratory action to check momentum. Largely a nocturnal feeder, flocks flying regularly to their feeding grounds around sunset. Flight strong and swift, with regular rapid wing-beats.
FOOD. Molluscs, crustaceans, insects, worms, and large quantities sometimes almost exclusively — of vegetable matter: grass- and weed seeds, berries, wild and cultivated rice, etc.
VOICE and CALLS. Very silent. A low *chuck-chuck* or plaintive *tu-wit* occasionally emitted on flushing.
BREEDING. Extralimital. Ruff renowned for its fantastic sparring tournaments or courtship displays. A number of males in variegated ornamental plumages assemble at selected dry spots in marshes known as 'leks' or 'hills', each occupying an adjacent 'territory' of half a square metre or so. The neighbours posture threateningly with ruff and ear-tufts erected, legs flexed, head lowered and bill pointing to the ground, and lunge and tilt and leap up and down in the air and at one another. Physiologically mature

• See Appendix

PHALAROPE

321

reeves visit the 'hills' from time to time and apparently mate promiscuously with the ruff of their choice. He takes no part in the nesting chores.

MUSEUM DIAGNOSIS. See under Genus. For details of plumage phases etc. see Witherby, 1940, 4: 284-6.

Moult. In keeping with its other unusual features, the moult pattern is also unique. Between two breeding cycles the male renews his body feathers not twice, as is normal with limicolines, but three times — twice on its breeding grounds and once in the winter quarters. He emigrates in this second non-breeding plumage (pre-nuptial) to his breeding grounds, moulting quickly into the ornamental nuptial dress after arrival there. This nuptial dress is worn for about two months only.

(For details of moults see Kozłowa, E., 1956, *Zool. Jour.* 35: 1908-10 — Russian, and Stresemann, E. & V., 1965, *L'Oiseau*, 35 (Special No.): 125-9 — German.)

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂♂	173-190	30-36	46-50	78-89 mm.
♀♀	150-166	29-31	41-44	64-70 mm.
	(from feathers)			(Baker)
	Wing		Weight	
			(early autumn)	
50 ♂♂	181-194 mm. (av. 186.9)		127-179 gm. (av. 150.9)	
50 ♀♀	149-163 mm. (av. 156.1)		81-118 gm. (av. 93.25)	
	No overlap in the sexes.		(SA)	

COLOURS OF BARE PARTS. Winter. Iris brown. Bill dark brown; particoloured in some individuals — orange or salmon near base. Legs exceedingly variable: olive, pinkish olive, yellowish olive, orange-olive, greyish olive, olive-plumbeous, greenish orange, bright orange, dull salmon-pink, or salmon.

Adults of both sexes *mostly* (but not invariably) have orange legs in autumn (September/October), but leg coloration by itself is no criterion of age. Moulting of the primaries at that period, however, is an infallible indication of adulthood. Young birds (i.e. those hatched in the same year) never have orange legs in September/October and they arrive in their Indian winter quarters with freshly moulted wing-quills — in reality carrying their first generation of flight feathers which still look fresh at the time.

MISCELLANEOUS. Ranked as a semi-sporting bird and excellent for the table. Longevity: longest period between ringing and recovery of an individual in India 8 years 9½ months.

Subfamily PHALAROPINAE: Phalaropes

Genus PHALAROPUS Brisson

Phalaropus Brisson, 1760, Orn. 1: 50; 6: 12. Type, by tautonymy,

Phalaropus Brisson = *Tringa fulicaria* Linnaeus

Lobipes Cuvier, 1817 (1816), Règne Anim. 1: 495. Type, by original designation

Tringa hyperborea Linnaeus = *Tringa lobata* Linnaeus

Anterior toes bordered throughout by a web divided into lobes very much as in coots and grebes. Similar to *Calidris* in other respects except that the female is much bigger and more brightly coloured than the male and is the dominant sex partner as in Jacanas and Painted Snipe. Wings long and pointed: first primary (as.) longest. Tail of moderate length and nearly square. Tarsus scutellated all

PHALAROPE

323

Male less brightly coloured than female with crown streaked like back (contra black in ♀), and with much white on throat and breast.

STATUS, DISTRIBUTION AND HABITAT. Accidental waif. Since the single specimen obtained by Blyth in the Calcutta market on 11.v.1846, there is no other record within our limits.

Extralimital. 'Breeds locally on the arctic coasts and islands of the Holarctic region. . . Winters at sea off the west coast of Africa and coast of Chile' (Peters). For details of range see Vaurie, 1965, 2: 441-2.

HABITS, FOOD, etc. as in 428.

BREEDING. Extralimital.

MUSEUM DIAGNOSIS. Short, broad, flattened bill distinguishes it from Rednecked Phalarope (428). For description of plumage phases etc. see Witherby, 1940, 4: 216-18.

428. Rednecked Phalarope. *Phalaropus lobatus* (Linnaeus)

Tringa lobata [sic] Linnaeus, 1758, Syst. Nat., ed. 10, 1: 148

(in America septentrionali = Hudson Bay)

Baker, FBI No. 2166, Vol. 6: 249

Plate 40, fig. 17 and Plate 41, fig. 12

LOCAL NAMES. None recorded.

SIZE. Grey Quail ±; length ♀ c. 19 cm. (7½ in.), ♂ smaller.

FIELD CHARACTERS. Like 427 a delicate sandpiper-like bird habitually seen swimming about buoyantly on ponds, lagoons, and the open sea. In winter chiefly grey above, white below, with a blackish eye-patch — rather reminiscent of Sanderling. Doubtfully separable from 427 except by those familiar with both species. May be distinguished from it by slightly smaller size, darker grey more streaked upperparts, more prominent white wing-bar in flight, and — on a good view through glasses — by the finer black bill, and blackish (not yellowish)

x c. 1

legs. Sexes alike in coloration; male smaller.

In contrast with stints and other small waders with which it feeds and flies, its characteristic habit of alighting on water (fresh and salt) and swimming on the surface instead of landing on squelchy mud and running about or wading is quite diagnostic.

In summer plumage (not normally seen in India) upperparts blackish grey with sides of neck and foreneck rich rufous. Male duller, and with the rufous broken across foreneck by a dark slaty area.

STATUS, DISTRIBUTION AND HABITAT. Winter visitor. Common offshore along the coastline of W. Pakistan (Makran, Sind), less so in NW. India (Kutch, Saurashtra), and in small numbers and patchily (regular or sporadic?) more or less off the entire coastline of peninsular India to East Pakistan. Ceylon (sporadic). Recorded from a few inland localities on spring and/or autumn passage: thus from Chitral (Drosh), Baluchistan (Quetta, Fort

322

CHARADRIIFORMES

round; a hind toe present. Bill slender, short and straight. Nostrils placed in a well-defined groove near base of bill.

Genus Holarctic with two species recorded in our area in winter.

Key to the Species

Bill flat; broader than tarsus and broader than high. *P. fulicarius*
Bill slender and subcylindrical; anteriorly narrower than the tarsus
..... *P. lobatus*

427. Grey Phalarope. *Phalaropus fulicarius* (Linnaeus)

Tringa Fulicaria Linnaeus, 1758, Syst. Nat., ed. 10, 1: 148

(in America = Hudson Bay)

Phalaropus fulicarius jerdoni Iredale, 1921, Bull. Brit. Orn. Cl. 42: 8

(Liefde Bay, Spitzbergen)

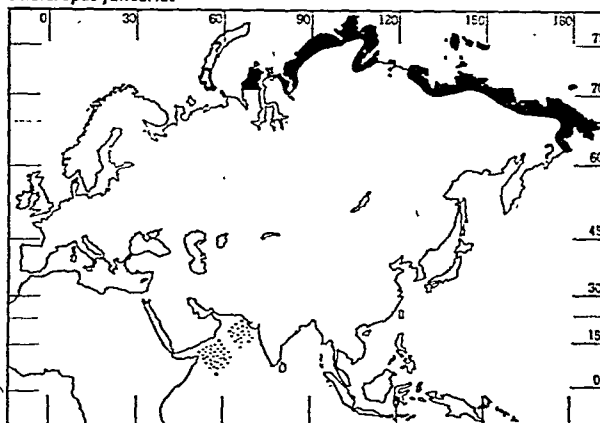

Baker, FBI No. 2165, Vol. 6: 248

LOCAL NAMES. None recorded.

SIZE. Grey Quail ±, length ♀ c. 20 cm. (8 in.), ♂ smaller.

FIELD CHARACTERS. Winter. A dainty sandpiper-like bird habitually seen swimming buoyantly on water, fresh as well as salt, often far out at sea. The unstriped grey and white plumage with a prominent dark patch from in front of eye to ear-coverts, thicker chiefly yellow bill, and yellow legs, help to distinguish it from Rednecked Phalarope (428) in winter. Sexes alike in winter plumage.

Summer plumage (unlikely to be seen in India): above, dark brown streaked or scalloped with chestnut-buff. Sides of face white. Below, chestnut.

Phalaropus fulicarius

■ Palearctic breeding range ▨ Winter

324

CHARADRIIFORMES

Phalaropus lobatus

■ Palearctic breeding range ▨ Winter

Munro), Sind, Delhi, Rajasthan (Bharatpur), Bihar (Patna), Karnataka (Bangalore) and Kutch (near Bhuj). Most abundant though rather patchy off the Sind and Makran coasts, sometimes within a few miles of land but more often well out to sea at 10 to 40 or more miles from the coastline. Affects shallow water in the Arabian Sea, the 200-fathom line apparently being its limit (Ticehurst). Frequents shallow jheels and ponds inland.

Extralimital. Breeds in Iceland, Spitzbergen, Faroes, Scandinavia, N. Russia and across northern Asia; also in extreme N. America (Alaska etc.). Winters at sea in the northwestern Indian Ocean, off the coasts of Peru and West Africa, between New Guinea and the Bismarck Archipelago, and in the Banda Sea. For greater details of range see Vaurie, 1965, 2: 442-3.

MIGRATION. No ringing data. Observed on passage in Makran and Sind, chiefly autumn: earliest September 2, latest May 20 (Ticehurst); Chitral September 14 (Fulton); Fort Munro, Sulaiman Hills, Baluchistan, September 25 (Waite). Latest inland dates late May in two successive years, 1948 and 1949, Kutch (Himmattinji), and June 1 Delhi (H. G. Alexander), all in partial summer plumage.

GENERAL HABITS. Ticehurst (Ibis 1924: 126) has given an excellent account of its habits in winter. Chiefly pelagic. Keeps in flocks of 20 to a hundred or more offshore. Extremely wild and unapproachable at sea, rising and scudding over the surface to re-settle at some distance even while the observer's boat is 200 yards away. In contrast, absurdly tame on inland waters (as also on its breeding grounds), parties feeding unconcernedly within a few metres of an observer. The birds keep to pools and shallow jheels, swimming about buoyantly like corks, spinning round and round to pick up food particles from the surface, making swift little darts here and

PAINTED SNIPE

325

there, head bobbing like a moorhen, or threading their way in single file through the more thinly scattered rushes. Flight swift and agile, in close-knit flocks, very like stints.

FOOD. Chiefly plankton, insects and larvae. Also small crustaceans, molluscs and worms.

VOICE AND CALLS. Not recorded in winter.

BREEDING. Extralimital. Courtship by female; incubation and raising family entirely by male.

MUSEUM DIAGNOSIS. See Key; for description of plumage Baker, loc. cit.; for details of plumage phases and morphology (also bionomics), Witherby, 1940, 4: 218-22.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂♂	106-110	20-24	19-21	43-47 mm.
♀♀	112-118	20-25	—	—
	(from feathers)			(Witherby)

Weight 20 ♂ ♀ (autumn/winter) 20-38 (av. 27.6) gm. — BNHS.

COLOURS OF BARE PARTS. Iris dark brown. Bill dark horny brown, orange at base. Legs and feet dull brown or fleshy brown.

Tibia pale orange; tarsus and feet black except lobes of web between inner and middle toe which are bright orange (D'Abreu).

Family ROSTRATULIDAE: Painted Snipe

Genus ROSTRATULA Vieillot

Rostratula Vieillot, 1816, Analyse: 56. Type, by monotypy, *Béassins de Madagascar*, Buffon = *Rallus benghalensis* Linnaeus

Bill slender and long but shorter than in most species of true snipe of the genus *Cepella* (p. 278), and not pitted at the end; tip slightly swollen and bent down; both mandibles grooved at the base. Nostrils at base of upper mandible. Tarsi strong, of moderate length. Tibia partly naked; toes long. Wings short, broad, rather lax: 1st and 2nd primaries (as.) longest and subequal. Tail of 14 feathers. Female larger and brighter coloured than male.

Represented by one resident species in our area.

429. Painted Snipe. *Rostratula benghalensis benghalensis* (Linnaeus)

Rallus benghalensis Linnaeus, 1758, Syst. Nat., ed. 10, 1: 153 (Asia)

Baker, FBI No. 2033, Vol. 6: 45

Plate 38, fig. 8 and Plate 41, fig. 16

LOCAL NAMES. *Rājchāhā* (Hindi); *Ohāri* (Nepal, Bihar); *Baggerji* (Bengal); *Pān lānā* (Gujarat, Maharashtra); *Ayle ulān* (Tamil, Madras); *Ullān kūniri* (Tamil, Ceylon); *Kālikāta* (Malayalam); *Rāja wātunā*, *Ulu kēnātunā* (Sinhala); *Kāngdrūk* (Manipur); *Doodidap gajao* (Cachar, Assam).

SIZE. Grey Quail +; length c. 25 cm. (10 in.).

FIELD CHARACTERS. A typical skulking rail with long, slender, straight snipe-like bill, slightly downcurved at tip.

Female. Above, chiefly metallic olive- or bronze-green with buff and blackish streaks and markings. Whitish 'spectacles' with a white patch

PAINTED SNIPE

327

spersed with deepish pools and soft muddy patches, and rather thick shrubby vegetation, in preference to squelchy paddyfields.

Extralimital. 'Africa south of the Sahara to Cape Province; Egypt; Madagascar; S. Asia from Asia Minor through Persia to S. and E. China, and Japan, south to Arabia, Sind, all India [including Burma], Ceylon, Malay Peninsula, and Cambodia; Philippines, Borneo, Sumatra, and Java' (Peters).

MIGRATION. Apart from local movements dependent on drought and flood conditions, some translimital migration would seem to be indicated by the puzzling, oft-quoted statement of Wollaston (if correct) that Painted Snipe¹ were among the Temminck's Stints, Pintail Snipe, and several other species of migrating birds seen at 17,000 ft. (c. 5200 m.) in September by the first Mount Everest expedition (*Ibis* 1922: 497; and Younghusband, Sir F., 1926, *The Epic of Mount Everest*: 154). No other evidence.

GENERAL HABITS. Largely crepuscular; much more active in the early mornings and evenings, and during night, than in daytime. Keeps singly or in small wisps and is reluctant to leave cover unless pressed. Flight slow and rail-like — legs dangling below for some distance then tucked under tail and trailing behind — the bird soon pitching into the reeds again. Strong and swift on its legs and usually runs a good distance through the undergrowth upon alighting, soon working its way back to where originally disturbed. Wounded birds swim effectively to evade capture, and also to cross narrow deep channels in the course of their feeding. Feeds by probing into squelchy mud as well as by a side-to-side scything movement of the bill in shallow water — reminiscent of the Spoonbill. Wags hindpart of body like sandpiper when feeding, which it sometimes does in exposed puddles far from cover.

FOOD. Molluscs, crustaceans, insects, worms, and vegetable matter — weed-seeds, paddy grains, etc.

VOICE AND CALLS. Female (ready-to-breed?) utters a rather metallic long-drawn oot, like the sound of blowing into a large-mouthed bottle. The calls begin around sunset and continue intermittently through the night, especially if moonlit; sometimes also in daytime in cloudy overcast weather. Repeated at the rate of 1 per second (or 3 in 2 seconds) in runs of 20 to 80 or so, with a break of a few minutes between each run. Single calls (not runs) also uttered by female in a 'roding' type of flight (cf. Woodcock) 3 or 4 metres above the marsh. Male has a squacky note, but whether this given in response to female's calls, or how occasioned, not known.

BREEDING. Female polyandrous and pugnacious as in Bustard-Quail (318, q.v.), and the dominant sex partner. She battles with rival females for the possession of successive husbands, and once secured and eggs laid leaves to him the onus of incubating them and raising the chicks. Meanwhile she sets out to make fresh conquests. No precise data available, but female believed to lay several clutches successively.

Season. Practically throughout the year, varying locally; chiefly July to September in India; November to April in Ceylon. *Nest*, a pad of grass or

¹ F. Ludlow suggests, with good reason, that this (or these) may possibly have been Wood Snipe (*Cepella leucorhynchos*) and not Painted Snipe, since the flight of the two species is very similar.

326

CHARADRIIFORMES

behind eye, and white bands over shoulders to sides of breast (reminiscent of the straps of a rucksack) distinctive. Below, chin, throat, and upper breast chestnut; lower breast blackish. Rest of underparts white. Easily differentiated from male in flight. Outside breeding period the sexes more or less alike and difficult to distinguish.

♀, x c. 1

Male less showy than female and lacking the chestnut and black on neck and breast.

Young (immature) ♂ ♀. Very similar to adult male but with throat entirely white; lower throat and foreneck washed with brown, with some dusky streaks (Sharpe).

For downy chick see Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident throughout the Indian Union and both Pakistans; locally to c. 1800 m. in the Himalayas. Also Ceylon in all zones and up to c. 1300 m. in the hills of Uva Province. Not observed in Nepal and in Andaman and Nicobar Is. Affects marshes inter-

Rostratula benghalensis

■ Distributional range

328

CHARADRIIFORMES

rushes (built by male) with a slight depression in the centre. Placed on the ground in a grass tussock on the edge of a marsh, or on bunds separating inundated paddyfields. Eggs, normally 4 — sometimes 3 — yellowish in ground colour, boldly and heavily blotched with blackish brown. Average size of 100 eggs 35.9 x 25.5 mm. (Baker). Incubation period unknown.

MUSEUM DIAGNOSIS. See under Genus (above); for description of plumage, Baker, loc. cit.

Chick (in down). 'Dull grey or buff-grey, with broad coronal and eye-streaks of rich brown; centre of back rich rufous with broad bands of black on either side and lateral bands of purplish brown from the wings to the thighs' (Baker).

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂♂	115-136	41-47	40-45	36-45 mm.
	(mostly over 124)			
♀♀	130-146	45-50	—	—
				(Baker)

Weight 23 ♂ ♀ (autumn) 106-151 gm. (aver. 125.9) — SA.

COLOURS OF BARE PARTS. Iris olive-brown to dark brown. Bill pale to dark fleshy brown or horny brown, greenish at base; more fleshy pink in breeding. Legs and feet yellowish to olive-green, sometimes tinged with brown or plumbeous.

Genus HIMANTOPUS Brisson

Himantopus Brisson, 1760, Orn. 1: 46; 5: 33. Type, by tautonymy,

Himantopus Brisson = *Charadrius himantopus* Linnaeus

Characterized by the enormous length of the legs. Both tibia and tarsus very to the former bare for over three-quarters of its length; tarsus reticulated throughout. No hind toe; outer toe joined to middle toe by a broad web, middle toe to inner a narrower one. Bill long, straight, and slender, the dertrum not swollen. Nostril long slits placed in the base of a groove running about half the length of upper mandible. Wing long and pointed: first primary (as.) longest. Tail short and even.

The genus ranges over the temperate and tropical areas of the Old and N worlds; represented within our limits by one species.

HIMANTOPUS HIMANTOPUS (Linnaeus)

Key to the Subspecies

Crown and nape black (ad. ♂♂, summer) or black variously mixed with white, or black concealed or subdued (ad. ♂♂ winter, and ad. ♀♀ summer and winter). Upperparts blackish, glossed metallic green (♂♂ summer and winter) or upperparts hair brown (♀♀ summer and winter). Breast suffused with mouse grey (juvenals)....*H. h. himantopus* Crown and nape whitish or merely sullied by dark bases of feathers showing through (♂♂ and ♀♀, summer).....*H. h. ceylonensis*

¹ Winter plumage not examined by us but presumably similar.

STILTS, AVOGETS, IBISBILLS

329

430. Indian Blackwinged Stilt. *Himantopus himantopus himantopus* (Linnaeus)

Charadrius Himantopus Linnaeus, 1758, Syst. Nat., ed. 10, 1: 151 (Southern Europe)
Baker, FBI No. 2130, Vol. 6: 193
Plate 39, fig. 8 and Plate 42, fig. 8

LOCAL NAMES. *Gāz pān*, *Tinghār* (Hindi); *Sārgān* or *Sārgān* (Bihari mirshikān); *Lāl gān*, *Lāl thēngi*, *Lām gōra* (Bengal); *Gūding* (Sind); *Pārilāl kāl tūllān* (Tamil).

SIZE. Grey Partridge ±, with bare slender legs c. 25 cm. (10 in.) long.

FIELD CHARACTERS. A lanky pied black and white marsh bird with straight slender black bill, pointed black wings, and enormously long, thin reddish legs which trail behind comically in flight, making its identity unmistakable even in the distance.

x c. 3

Male (adult). Mantle and wings glossy metallic black; rest of plumage above and below largely glistening white. A few black spots on head, and pale grey-brown in tail. Undersurface of wings black.

Female (adult) has black portions of male replaced by brown, and the white head and hindneck sullied with brownish grey. Summer and winter plumages differ in details.

For downy chick see Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident—breeding in suitable localities, migrating locally under stress of water conditions—throughout the Indian Union, both Pakistans and Nepal. Normally to c. 1500 m. in Kashmir Valley (uncommon); one at c. 3600 m. (Vishan Sar, July—on migration?). Not in Andamans or Nicobars. Observed once in the Maldives where race and status unknown but presumed a vagrant (Phillips). Ceylon has an endemic race (431). Affects marshes both freshwater and tidal, jheels, village tanks, irrigation reservoirs, lagoons, salt-pans, etc. Sometimes inundated ploughed fields, but hardly ever the seashore.

EXTRALIMITAL. 'Breeds locally in the Mediterranean region; about the mouth on the Danube; steppes of S. Russia; S. Asia east to China and S. Arabia, India, Ceylon [now race *ceylonensis*], and the Malay States; Egypt; Africa south of the Sahara; Madagascar. Migratory only in the northern part of its range' (Peters).

MIGRATION. Birds ringed in Bharatpur in autumn and winter recovered in NW. Pakistan and N. Afghanistan in spring (late April) clearly indicate extralimital seasonal movement. Recorded by Ticehurst as mainly winter visitor (locally abundant) in Sind, appearing in the Karachi neighbourhood early in August, its numbers increasing during the month but soon dwindling again.

STILTS, AVOGETS, IBISBILLS

331

flapping their wings and jumping about in a frenzied manner. Incubating birds not shy, permitting close approach before leaving nest, and thereupon demonstrating noisily about the intruder, flying high in the air and hovering with loud incessant calls.

MUSEUM DIAGNOSIS. For description of the various plumage phases, structure, etc. see Witherby, 1940, 4: 406-8.

CHICK (in down). 'Head and upperparts mottled pale buff and black; black spinal line; black line from base of bill to eye, and on ulna. Round eye and whole of underparts pale buff' (Ticehurst).

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂♂	240-253	60-69	c. 115-145	80-90 mm.
♀♀	222-240	54-69	—	—
	(from feathers)		(Baker, Witherby)	
13 ♂♀	Wing 202-249 (aver. 231.7); weight (autumn) 163-208 gm. (aver. 196.2)		— SA.	
Weight 20 ♂♀	(autumn/winter, ad. & imm.) 112-223 (av. 177.1) gm. — BNHS.			

COLOURS OF BARE PARTS. Iris bright red. Bill black. Legs and feet crimson; claws black.

431. Ceylon Blackwinged Stilt. *Himantopus himantopus ceylonensis* Whistler

Himantopus himantopus ceylonensis Whistler, 1944, Spolia Zeylanica 23(3, 4): 277 (Kalawewa, Ceylon)
Not in Baker, FBI

LOCAL NAMES. *Kelapu-kirālā* (Sinhala); *Pavala kālī* (Tamil).

SIZE. As 430.

FIELD CHARACTERS. As of 430, q.v.

STATUS, DISTRIBUTION AND HABITAT. Race peculiar to Ceylon. Plentiful round large tanks and lagoons throughout the low-country Dry zone (Phillips).

GENERAL HABITS. Not different from the Indian race. (Cf. also Henry, G. M., 1955, *A Guide to the Birds of Ceylon*: 292-3.)

BREEDING. Season, May, June, and July; occasional nests in April and August (Phillips). Nest and eggs similar to 430.

MUSEUM DIAGNOSIS. No distinct breeding plumage as in male of the nominate form. Brown back of female darker than in Indian birds. 'The males differ from the typical form which has the crown and nape black in breeding plumage in having those parts white merely sullied by the dark bases of the feathers showing through. The females have the brown back darker than in European birds' [nominate] (Whistler, H., loc. cit.).

330

CHARADRIIFORMES

Himantopus himantopus

Distributional range

- 1 *H. h. himantopus* (430).
2 *H. h. ceylonensis* (431).

GENERAL HABITS. Gregarious—usually by itself, occasionally with Godwits and other waders—in small parties or fair-sized flocks and larger congregations of a hundred or more. Often wades into deepish water almost to the belly, walking with an awkward high-stepping gait lifting each foot clear of the surface behind and putting it forward with deliberation. The long stilt-like legs enable it to tap food supplies normally out of reach of most other waders. While feeding, head often completely submerged. Flight feeble and flapping, the black undersides of the pointed wings and the absurdly long trailing legs giving it a singular silhouette.

FOOD. Molluscs, worms, aquatic insects, and small seeds of sedges and marsh plants.

VOICE AND CALLS. A shrill piping *kip, kip*, usually in flight. When agitated, a squeaky *chek-chek-chek* etc. reminiscent of a Moorhen, with the timbre of the Redwattled Lapwing's calls. This uttered noisily while wheeling and demonstrating above the intruder.

BREEDING. Season, principally between April and August. Nest, a hollow depression in the ground on the dry margin of a jheel or on an islet, or a raised platform of *kānkār* (pebbles) in a shallow salt-pan—lined with vegetable scum off the water, grass, or similar material. Sometimes nests in colonies maybe of several score pairs. Eggs, normally 4, sometimes 3, exceptionally 5, light drab in colour densely blotched with black. In size, the longish peg-top shape and general appearance, they are replicas of Redwattled Lapwing's (366). Average size of 100 Indian eggs 44×31 mm. (Baker). Both sexes incubate; incubation period undetermined, believed to be 25-26 days. When nests approached the birds protest loudly,

332

CHARADRIIFORMES

Genus RECURVIROSTRA Linnaeus

Recurvirostra Linnaeus, 1758, Syst. Nat., ed. 10, 1: 151. Type, by monotypy.

Recurvirostra acrosetta Linnaeus

Bill very long, slender, flexible, tapering and curved upwards towards the end; both mandibles flattened or depressed. Nostrils slit-like, placed near base of upper mandible in an ill-defined groove extending for less than half length of bill. Wings long and pointed: 1st primary (as.) longest. Tarsus and bare tibia long; tarsus reticulated. Hind toe small, furnished with a claw; anterior toes deeply webbed, but webs notched in the middle.

Represented by one species in our area.

432. Avocet. *Recurvirostra acrosetta* Linnaeus

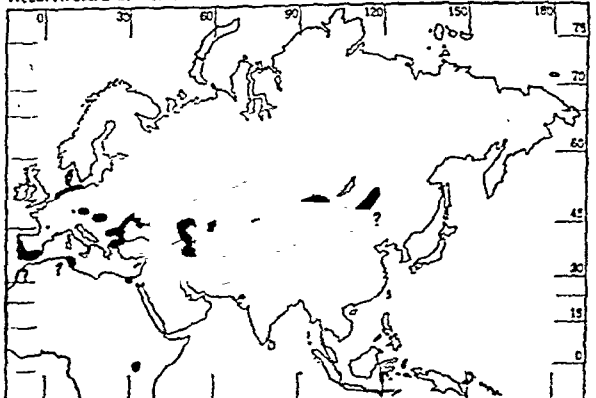

Recurvirostra Acrosetta Linnaeus, 1758, Syst. Nat., ed. 10, 1: 151
(in Europa australiore = Italy)
Baker, FBI No. 2131, Vol. 6: 195
Plate 39, fig. 6 and Plate 42, fig. 10

LOCAL NAME. *Kūyā chāhā* (Hindi); *Kūni āchichān* (Tamil).

SIZE. Grey Partridge ±; more leggy. Length c. 46 cm. (18 in.).

FIELD CHARACTERS. An elegant black-and-snowy white (pied) marsh bird unmistakable with any other by its unique slender black upcurved bill and longish bare blue legs. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Breeding regularly or sporadically (?) in N. Baluchistan and Kutch. Mainly winter visitor: fairly common in West Pakistan (Baluchistan, Sind) and NW. India (Banaskantha, Kutch,

Recurvirostra acrosetta

Breeding range

STILTS, AVOCETS, IBISBILLS

333

Saurashtra). Less common, sporadic and/or occasional, in Nepal and Kashmir and over the rest of the Indian Union including coastal Maharashtra, Punjab, Delhi, U.P., Bihar, Orissa, Assam and Manipur. Recorded on Rameswaram I. and at Point Calimere (Madras State); not in Kerala, Andaman and Nicobar Is. or the Maldives. Rare straggler to Ceylon, observed in February and July. Affects jheels and swamps, lagoon shores, tidal creeks and mudflats, and the sea coast.

Extralimital. Breeds locally from Holland eastward through the region of the Black and Caspian Seas, Kirghiz Steppes, the upper Yenisey and Transbaikalia, south to the Mediterranean countries, Persia, Turkistan and N. China; breeds also in various parts of tropical and southern Africa, possibly in Madagascar. Migrates from the northern part of its breeding range to Africa, India, and S. China (Peters).

Migration. No ringing data. Earliest date at Karachi 28 August; latest 24 May (Ticehurst). Owing to its dual status, observations on movements ambiguous.

GENERAL HABITS. Keeps in pairs and small parties — sometimes flocks of a hundred or more. The birds run about and feed on squelchy mudflats or by wading in shallow water. The curious upturned bill is directed obliquely against the ground — like a hockey stick held in play — the curved part skimming the surface. It is then moved back and forth in a rotary sweeping motion churning up the bottom mud along with minute organisms which are collected in the mandibles. Sometimes feeds in deeper water, its webbed feet being well adapted for swimming, and frequently up-ends like a duck to reach the bottom.

FOOD. Tiny molluscs, crustaceans and insects.

VOICE AND CALLS. A clear loud, rather high-pitched *kleeit* uttered several times in succession, usually on the wing. When agitated by proximity of observer to nest, a continuous screaming *kleeit-kleeit-kleeit* (at the rate of c. 3 per second), of the timbre of Stone Curlew's (*Burhinus*) calls, while wheeling overhead.

BREEDING. Nesting within Indian limits, in the Great Rann of Kutch — discovered for the first time in April 1945 (Salim Ali, JBNHS 45: 420-1). The colony consisted of over a thousand birds. More than 150 nests counted within an area of c. 2 hectares, and numerous others scattered far and wide. On April 21 most nests contained full clutches, some incomplete. Only two downy chicks observed and perhaps several overlooked, but general hatching had not yet commenced. Owing to remoteness of the area and difficulty of access, it remains undetermined whether the breeding in the Rann is regular or sporadic. *Nest*, in some cases a bed of *kankar* (mud-pellets), but mostly a mere shallow scrape or unevenness in the hard sun-baked ground. Eggs, 4, some shade of olive-brown, boldly blotched with blackish; in shape and coloration very close to eggs of both Redwattled Lapwing and Stilt. Average size of 16 Kutch eggs 49.25 × 35.0 mm. (SA). Incubation by both sexes; period recorded elsewhere as 22-24 days. On an observer's approach the birds left their nests and started running about here and there, crouching low, raising their wings vertically back to back, and giving the 'broken-wing' diversionary display. Over 30 birds occasionally thus engaged at the same time.

STILTS, AVOCETS, IBISBILLS

335

blackish cross-bars, broad near tips of outer rectrices. A partially concealed white wing-patch. *Below*, sides of head, neck, and upper breast bluish grey. A broad black gorget separated from upper breast by a narrow white band. Rest of lower plumage white. Sexes alike.

In flight, which resembles the Stone Curlew's, the neck and long curved bill are stretched out in front, and the posterior end of the bird looks rather truncated. White wing-patches and black breast-band very prominent.

STATUS, DISTRIBUTION AND HABITAT. Resident in the Himalayas between c. 1700 and 4400 m. from Gilgit, Ladakh and Kashmir, through Garhwal, Kumaon, Nepal, Sikkim and Bhutan to extreme eastern NEFA (Luhit

Ibidorhyncha struthersii

Distributional range

Frontier Division). In winter, while some birds continue to remain at high elevations a great many descend into the foothills of northern W. Bengal and eastern Assam north of the Brahmaputra, being found on the Teesta and most other east-Himalayan rivers where they debouch into the plains. Affects shingle banks and islets in fast-flowing Himalayan streams.

Extralimital. 'High plateaus of central Asia from W. Turkistan to Chihili south to Kashmir, the Himalayas and northern Assam' (Peters).

GENERAL HABITS. Keeps in pairs or small parties of 6 to 8 birds on shingle banks or islets in comparatively placid stretches of fast-flowing glacier streams. Sometimes feeds in short grass by a river, running a few steps, stopping abruptly and tilting forward like a plover. Has characteristic habit of wading breast deep and ducking whole head and neck under water, thrusting its long bill under the submerged pebbles for food. When feeding among water-worn boulders, curves its bill around the front of the stone, sometimes inserting it from one side. Bill eminently adapted; curved in

334

CHARADRIIFORMES

Nearest previous breeding record from N. Baluchistan (small numbers Khushdil Khan lake) where full clutches found on June 10 and 17 in different years (Ticehurst, JBNHS 32: 82).

MUSEUM DIAGNOSIS. See under Genus; for description of chick in down, plumage phases and structure, etc. Witherby, 1940, 4: 412-13.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	220-235	84-91	c. 84-90	86-90 mm. (Harter)

No appreciable size difference between the sexes.

COLOURS OF BARE PARTS. Iris reddish brown or red. Bill black. Legs and feet pale bluish grey.

Family IBIDORHYNCHIDAE: Ibisbills

Genus IBIDORHYNCHA Vigors¹

Ibidorhyncha Vigors, 1832 (1830-31), Proc. Zool. Soc. London: 174

Type, by monotypy, *Ibidorhyncha struthersii* Vigors

Bill long, hard, slender, and curved down over nearly half its length. Nostril linear, placed at base of bill in a groove which extends over more than half length of bill. Tarsus comparatively short; reticulated throughout. No hind toe; outer and middle toes connected by a deeply indented small web; web between middle and inner toes obsolete. Wing very square: first 3 primaries (as.) subequal; inner secondaries almost as long.

433. Ibisbill. *Ibidorhyncha struthersii* Vigors

Ibidorhyncha Struthersii Vigors, 1832 (1830-31), Proc. Zool. Soc. London: 174 (Himalayas)

Baker, FBI No. 2132, Vol. 6: 196

Plate 39, fig. 16 and Plate 42, fig. 3

LOCAL NAME. Puggah (Hill Min).

SIZE. Grey Partridge +; length c. 41 cm. (16 in.).

FIELD CHARACTERS. A greyish brown sandpiper-like bird with black facial mask and breast-band, and long downcurved red bill. *Above*, anterior face (including throat) black. Rest of upperparts largely ashy grey-brown; rump feathers with basal black markings. Tail ashy grey with narrow wavy

× c. 1/4

¹ The familial relationships of this genus are uncertain, see Verheyen, R., 1958, Inst. roy. Sci. nat. Belg. 34(18): 1-31.

336

CHARADRIIFORMES

such a way that it fits neatly round the boulders when the bird is probing for food (Hingston). The rounded profile and grey-brown coloration of the Ibisbill's back obliterate it in an astonishing way in its native habitat of smooth water-worn stones. When alarmed or inquisitive it bobs or 'pumps' its head and neck jerkily up and down and slowly wags the tail end, very like a Greenshank. Usually shy, flying off from an observer at long range, but has a curious habit of doubling back after some distance to fly overhead. Flight reminiscent of Stone Curlew.

FOOD. Insects, molluscs, crustaceans, worms, and small fish (?).

VOICE AND CALLS. A loud, ringing single note or 'whistle' quickly repeated: *tee-ti-ti-ti-ti-tee* of distinctly sandpiper quality, uttered in flight. 'When disturbed emits a rather shrill mournful cry, something resembling that of a Greenshank' (B. B. Osmaston). A pretty trilling song by the male (?) from a distance prior to relieving his mate at the nest has been recorded by SA — like something between the nuptial song of the Spotted Sandpiper (*Tringa glareola*) and of the Curlew (*Numenius arquata*). This is responded to by the incubating partner with loud *lilee* notes. Relief announces his progress towards nest by a frequent sandpiper-like *tit-tit* but of a different timbre.

BREEDING. An early nester. *Season*, end March (even before ground clear of snow) to mid May; exceptionally into early June. *Nest*, a shallow depression on the raised portion or ridge of a shingly islet in a glacier stream amongst grey water-worn pebbles; usually unlined, occasionally with a tamped-down bed of tiny pebbles. Incubating bird merges into the rounded stones in a miraculous way becoming completely invisible when still. Eggs, 4, large for the bird, fine-textured broad ovals, drab grey or greenish grey in ground colour, spotted and speckled with dark brown, chiefly towards the large end. Average size of 52 eggs 51.0 × 36.9 mm. (Baker). Incubation by both sexes; period undetermined. Observations by SA at a nest in Sikkim revealed that not only the pair but three birds were clearly interested in it, suggesting the need for a proper investigation of the bird's breeding biology.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

Chick (in down) 24 hrs. old. 'Head covered with white down with black hair-like tips; hindneck greyish white; back densely covered with white down, tinged with fawn and minutely freckled with black; hinder quarters similarly marked but more strongly washed with rufous; an indistinct line of black and rufous feathers from the angle of the mouth through the eye; underparts silky white. Bill black; feet fleshy with plumbeous patches on the joints; iris dusky brown. Culmen 16 mm.; tarsus 24 mm.' (Ludlow).

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	230-245	68-80	c. 47-49	113-120 mm. (Baker)

Weight 1 ♂ 295 gm. (BB), 2 ♀♀ 271, 318 gm. (Diesselhorst).

COLOURS OF BARE PARTS. Iris crimson. Bill dull reddish brown to scarlet-red. Legs and feet pinkish grey ('non-breeding and young') to blood red ('breeding adults' — Baker). 'Livid and greenish grey' (breeding) — B. T. Phillips.

CRAB PLOVER

337

Family DROMADIDAE: Crab Plovers

Genus DROMAS Paykull

Dromas Paykull, 1805, Kongl. Vet.-Acad. Nya Handl. 26: 182. Type, by monotypy, *Dromas Ardeola* Paykull

Bill longer than head, strong, smooth and compressed; culmen curved. Nostril placed in a small depression at base of bill; no groove; angle of lower mandible prominent and close to base. Wings long and pointed: 1st primary (as.) longest. Tail very slightly graduated; almost square. Half tibia bare; tarsi long, shielded in front and behind; toes long, the 3rd and 4th joined by a broad web, the 2nd and 3rd by a small one; middle claw broad and pectinate, or notched, on the inner dilation. Feathers of interscapular region much lengthened and covering the lower back.

434. Crab Plover. *Dromas ardeola* Paykull

Dromas Ardeola Paykull, 1805, Kongl. Vet.-Acad. Nya Handl. 26: 182, 188, pl. 8 (India)

Baker, FBI No. 2057, Vol. 6: 94

Plate 39, fig. 7 and Plate 42, fig. 9

LOCAL NAMES. *Eshanga*, *Teyrasa* (Maldives Is.); *Cummernelmoo* (Car Nicobar).

SIZE. Grey Partridge +; length c. 41 cm. (16 in.).

FIELD CHARACTERS. A rather dumpy piebald maritime wader. In flight the overall white plumage with black back and wing quills, a small but striking black patch around eye, and particularly the rather heavy black

× c. 1/4

tern-like bill simplify its differentiation from other pied waders, e.g. Avocet, Stilt, Oystercatcher. Sexes alike.

Young (immature) has the crown and neck pale grey, the former streaked with dark brown; back, scapulars and tail brownish grey.

For downy chick see Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Winter visitor in small numbers, locally and sporadically, to the sea coasts of W. Pakistan (Makran, Sind) and peninsular India, northern Ceylon (resident ?), Andaman, Nicobar, Maldives, and Laccadive islands. [E. Pakistan?] Affects tidal mudflats and estuaries, lagoon shores, coral reefs exposed at low tide, etc.

Extralimital. 'Northern and western shores of the Indian Ocean, Red Sea and the Persian Gulf, south to Natal and east to India; islands in the Red Sea; Laccadive and Andaman Is., Comoro Is., Aldabra and Madagascar' (Peters).

GENERAL HABITS. Essentially maritime; gregarious. Keeps in small parties and large flocks — of up to 60 or 70 birds recorded from the Andamans. Sometimes solos. Usually very shy. Largely crepuscular, feeding like plovers, running about with mincing steps, stopping abruptly and tilting forward at an oblique angle to pick up food. Very close in general behaviour

APPENDIX

339

BREEDING. As 257.

MUSEUM DIAGNOSIS. See Key to the Subspecies. Paler than *asiatica* (255) and with no trace of reddish wash on upperparts. Pale streak markings on mantle prominent, but not as bold as in *pusjabi* (256). Chin and throat dark chocolate-brown (contra chestnut in nominate *asiatica*).

MEASUREMENTS AND COLOURS OF RARE PARTS. As in 255.

p. 89. Obtained in Myitkyina dist., Burma (Hpungang Pass, 27°30' N., 96°48' E., c. 3050 m.) September 1969 (U Tun Yin in *epist.*) — thus the first record east of 93°.

p. 90. MISCELLANEOUS. The stiff primary and tail quills are highly prized for making the vanes of arrows in Bhutan where archery is the national sport.

p. 129, line 4. Sri Lanka, 1 record (CBCN, Feb. 1978).

p. 148. In the second edition of Ripley's *Synopsis of the Birds of India and Pakistan* the order of Nos. 327-339 is: 329, 330, 327, 328, 333, 331, 332, 334, 339, 340, 335/336, 337, 338.

p. 181. For further recovery data see JBNHS 65: 784-93, 66: 174-82, 630-31, 68: 267-9.

p. 185. The male American Finfoot, *Heliornis fulica*, is reported to carry newly hatched chicks in pleated skin pockets under wings (10th Annual, 1971, *Living Birds*, Cornell Lab. Ornith.).

p. 198. Following recent taxonomic revisions in the Order Charadriiformes, the second edition of Ripley's *Synopsis of the Birds of India and Pakistan* places the families Rostratulidae, Recurvirostridae, Ibisididae, Dromadidae, Burhinidae and Glareolidae before Charadriidae.

p. 289. A bird ringed in Bharatpur (27°14' N., 77°28' E.) 29.i.1969, recovered in Alma Ata region (45°53' N., 74°50' E.) 4.x.1969. Another ringed in the same locality 7.iii.1970, recovered in Kemero region (53°37' N., 87°20' E.) 30.viii.1970 — both in Kazakh SSR.

p. 302. A bird ringed in Bharatpur (27°14' N., 77°28' E.) 3.xi.1967, recovered in Yakutian ASSR (68°14' N., 145°21' E.) June 1970 — c. 6250 km. NE.

p. 309. A bird ringed in Kutch (23°14' N., 68°45' E.) 13.xii.1970, recovered in Kazakh SSR (53°55' N., 69°17' E.) 19.x.1972 — c. 3500 km. N.

p. 311. A bird ringed at Point Calimere, Tamil Nadu (10°18' N., 79°52' E.) 25.iv.1970, recovered in Kazakh SSR (43°36' N., 77°03' E.) 17.ix.1971 — c. 3700 km. N.

p. 320. Aberrant migration once recorded. A bird ringed in East Africa (Lake Nakuru, Kenya, 0°26' S., 36°06' E.) 12.iv.1969, recovered near Meerut, U.P. (29°00' N., 77°42' E.) 16.ii.1973. *The Ring*, Vol. 7, No. 79/1974 — 2.

338

CHARADRIIFORMES

to Stone Curlew. Flight reminiscent of Bronzewing *Jaçana* (*Metopidius indicus*) with legs trailing behind.

FOOD. Chiefly crabs. One examined by Hume in the Andamans had fed entirely on the species *Gonodactyla chiragra*.

VOICE AND CALLS. According to Baker 'it is said to have a low rather musical call'. Shrill notes *chuk-chuk-chuk-chuk* uttered in the vicinity of the nest-holes. A continuous *chuk-chuk* kept up at night (Cheeseman).

BREEDING. Extralimital as far as known, but may turn up in NW. Ceylon as reported by Parker in 1881 (SF 9: 482), not since confirmed. Season in the Persian Gulf islands May-June. Nests colonially 'rabbit-warren' fashion in holes in sandbanks on coral reefs, apparently made by crabs and enlarged to suit. Burrows 15-20 cm. in diameter, a metre or more deep, ending in an enlarged egg-chamber. Egg — invariably a singleton — pure white and quite unlike the egg of any other Charadriine bird. It is enormous in size, being quite as large as the egg of *Exacus recurvirostris* (437), a bird double the weight of the Crab Plover. Average size of 30 eggs 65.4 × 45.9 mm. (Baker). Share of the sexes in the domestic chores, and period of incubation, undetermined. Curiously enough although the bird lays only a single large egg, it has two lateral brood patches like other waders which normally lay 3 or 4.

MUSEUM DIAGNOSIS. See under Genus; for details of plumage, Baker, loc. cit. Chick (in down). 'Entirely covered with long, very pale smoky grey down, darker on forehead and round eyes. Legs slate grey. The character of the down is more Larine than Limicoline, and lacks the mottling and lines which the latter nearly always show' (Ticehurst). 'Keel on gonyx well developed' (Meinertzhagen). Downy chicks, unlike those of other Charadriines, are helpless and cannot run or even walk for the first few days.

MEASUREMENTS

	Wing	Bill (from feathers)	Bill (from skull)	Tarsus	Tail
♂♂	202-225	55-61	60-70	88-100	64-76 mm.
♀♀	201-216	54-56	62-66		(Baker, Whistler)

Weight 6 ♂♀ (autumn/winter) 230-300 (av. 265.1) gm. — BNHS.

COLOURS OF RARE PARTS. Iris brown. Bill black. Legs and feet greyish white to pale glaucous blue.

APPENDIX

p. 48. 257a. **Tamil Nadu Jungle Bush Quail.** *Pardicula asiatica vellori* Abdulali & Reuben

Pardicula asiatica vellori Abdulali & Reuben, 1964, Jour. Bom. nat. Hist. Soc. 64(3): 690 (Vellore, North Arcot district, Tamil Nadu)

LOCAL NAMES. None recorded.

SIZE AND FIELD CHARACTERS. As of 255, q.v. See Key to the Subspecies.

STATUS, DISTRIBUTION AND HABITAT. Resident. North Arcot district, Tamil Nadu, probably extending to Shimoga (Karnataka) and Palkonda Hills (northeastern Andhra Pradesh) — apparently intergrading with 255 — and presumably south through Tamil Nadu except for the range of *vidali*. Plains and hills up to c. 1500 m. — dry scrub-and-bush country.

GENERAL HABITS, FOOD, VOICE AND CALLS. As of 255.

Order CHARADRIIFORMES (cont.)¹

Family BURHINIDAE: Stone Curlews, Thick-knees

For morphology and other details see Stresemann, E., 1927-34, *Aves*: 775; Baker, E. C. S., 1929, *FBI* 6: 76 (Oedienemidae); Van Tyne, J., & Berger, A. J., 1959: 445; Pittman, C. R. S., 1964, Article 'Thickknee' in Thomson, A. L. (ed.), *New Dict. Birds*, London and New York.

Key to the Genera

Page

- Bill much longer than head and compressed laterally.....*Esacus* 4
- Bill not longer than head and not compressed.....*Burhinus* 1

Genus BURHINUS Illiger

Burhinus Illiger, 1811, *Prodromus*: 250. Type, by monotypy, *Charadrius magnirostris* Latham

Bill shorter than head, stout, straight, broader at base than high. Nostrils elongate, placed in a shallow groove. Forehead high; eyes very large. Wing long and pointed: 2nd primary (as.) longest. Tail of 12 slightly graduated feathers. No hind toe; nail of middle toe broad and dilated on the inner side.

BURHINUS OEDICNEMUS (Linnaeus)

Key to the Subspecies

- Larger, wing c. 228 - 244 mm.; paler and less buff.....*B. o. harterti*
- Smaller, wing c. 203 - 222 mm.; darker and more buff.....*B. o. indicus*

435. Persian Stone Curlew, *Burhinus oedienemus harterti* Vaurie

Burhinus oedienemus harterti Vaurie, 1963, *Amer. Mus. Novit.*, No. 2131:2 (Kafir Kala, northern Khorasan, eastern Iran)

Cf. Abdulali, H., 1970, *JBNHS* 67: 288
Baker, *FBI* No. 2048, Vol. 6: 79

LOCAL NAMES. *Kārwānāḥ*, *Bārsiri* (Hindi).

SIZE. Grey Partridge +; length c. 41 cm. (16 in.).

FIELD CHARACTERS. As in the Indian race (436), q.v.

STATUS, DISTRIBUTION AND HABITAT. Resident, with some local movements: West Pakistan (Baluchistan, Sind, W. Punjab) and NW. India south through Rajasthan and N. Gujarat to Kutch, the population there intergrading with 436. Affects open semi-desert and stony scrub country, dry river- and tank beds with babool groves and tamarisk jungle, etc.

EXTRALIMITAL. Northern Africa from Morocco to Egypt, south to the Tademmat Plateau, Tuareg Mts and Faiyum; Crete, Cyprus; southern Palestine south to Sinai; desert of Kara Kum, and Afghanistan southward to the Persian Gulf, Baluchistan, and the Indian Desert (after Peters).

¹ *Synopsis*, 2nd edition, following recent revisions in this Order (Charadriiformes) by Jehl, J. R., 1968, *Mem. San Diego Soc. Nat. Hist.* 3: 1-53, places the families Burhinidae and Glareolidae along with Rostratulidae, Ibisorhynchidae and Dromadidae before Charadriidae.

STONE CURLEWS, THICK-KNEES

— even rambling jungly gardens in urban areas, e.g. New Delhi. In Madhya Pradesh often found in the same facies as Painted Spurfowl (*Gallopodiceps lunulata*).

EXTRALIMITAL. Burma, south-west and central Thailand, and Cambodia.

GENERAL HABITS. Terrestrial, cursorial, largely crepuscular and nocturnal. Usually seen in pairs or small parties of 5 or 6; in winter sometimes loose gatherings, or flocks, of up to 50 or more. Sedentary and parochial, inhabiting the same grove or patch of scrub jungle day after day, but subject to erratic local movements in winter. Sluggish during daytime, spending the hot hours under a shady grove or in shrubbery, lying low and flushed only by a dog or beaters, or when almost trodden on. The birds then fly a short distance low over the ground, running to hide themselves upon alighting. When suspicious or alarmed they scuttle off with quick pattering steps, slinking furtively — neck retracted, head ducked — occasionally squatting and 'freezing' with neck pressed flat on the ground, the large unblinking eye surreptitiously following the intruder's movements. In this posture the bird's plumage gives it perfect camouflage even at close range, magically transforming it into a pat of desiccated cowdung! Flight strong, with action reminiscent of both plover and bustard. Emerges into open clearings at dusk to feed, and is partial to roads through forest. Runs ahead of an approaching car, taking short flights in the beam of the headlights and momentarily re-alighting to be instantly disturbed again. In the darkness the peculiar flickering or vibrating wing-tips and the white markings on the wings proclaim its identity.

FOOD. Insects, worms, slugs, small reptiles, mice (?), along with which is usually swallowed a quantity of grit; occasionally some seeds. Among stomach contents the following insects have been identified: *Chrologonus* sp., *Himatium* sp., carabid and tenebrionid beetles, *Camponotus compressus* ants, and the mole-cricket *Gryllotalpa africana* (Mason & Lefroy, 1912).

VOICE AND CALLS. A series of sharp, clear, quick-repeated whistling screams pick-pick-pick-pick, often ending up with pick-wick, pick-wick, pick-wick, etc. somewhat slower in tempo with accent on second syllable. Timbre of call reminiscent of curlew. Mostly heard at dusk and dawn; frequently throughout moonlit nights. The birds are particularly noisy during the breeding season, often engaging in uneven duets or trios from different quarters. Also a single whistling scream, slowly repeated.

BREEDING. Season, February to August, chiefly March and April. In Ceylon April to September, chiefly June and July. Nest, a shallow unfilled scrape on stony ground at the base of a bush, grass-tusssock, clod of earth, or stone, in a dry shingly river bed, mango orchard or waste land. Eggs, normally 2 — exceptionally 3 — pale stone-colour or buff, blotched and smudged with blackish brown, sometimes strongly tinged with purplish or reddish, and with secondary grey markings. Variations occur. The shape varies from broad to long oval, generally quite obtuse at the smaller end, rarely rather pointed. Average size of 68 eggs 47.6 × 34.7 mm. (Baker). Incubation by both sexes but chiefly by female. When one bird is sitting, the other usually keeps guard in the proximity of the nest. Downy chicks as cryptically coloured as the eggs, less active than in most other plovers during the first few days; squatting doggo on approach of an intruder and

GENERAL HABITS, FOOD, VOICE AND CALLS. As in the Indian race (436). BREEDING. Season, nest, and eggs as in the Indian race. Eggs have been taken round Karachi and elsewhere in Sind, and near Dera Ismail Khan in the former N.W.F. Province (W. Pakistan). — Average size of 15 eggs 48.7 × 36.6 mm. (Baker).

MUSEUM DIAGNOSIS. The race *harterti* is paler and, on an average, larger than *indicus* of peninsular India and Ceylon (Vaurie, loc. cit.). Birds from our arid north-western portions (Sind, Rajasthan, N. Gujarat, Kutch) are intermediate, but closer to *indicus* in all respects.

MEASUREMENTS. Five examples from Gujarat measure:

	Wing	Bill (from skull)	Tarsus	Tail
4 ♂♂	223-227	44-46	82-88	115-116 mm.
1 ♀	217	46	81	107 mm. (SA)

COLOURS OF BARE PARTS. As in 436.

436. Indian Stone Curlew. *Burhinus oedienemus indicus* (Salvadori)

Oedienemus indicus Salvadori, 1865, *Atti Soc. Ital. Sci. Nat. Milano* 8: 381 (India)
Burhinus oedienemus mayri Koelz, 1939, *Proc. Biol. Soc. Wash.* 52: 82 (Londa, Bombay)
Baker, *FBI* No. 2047, Vol. 6: 77

Plate 39, fig. 14 and Plate 42, fig. 11.

LOCAL NAMES. *Kārwānāḥ*, *Bārsiri* (Hindi); *Lambi* (falconers); *Kharma*, *Chhāḥ* *shilabāḥ* (Bengal); *Kalleḍu* (Telugu); *Kānāl masāl* (= jungle hare), *Kannāḍi āl* *kāṭti* (Tamil); *Vāyālkānnāḍ* (Malayalam); *Gōlu kiralāḍ*, *Gōlu kiralā* (Sinhala); *Musal* *kinandi* (Tamil, Ceylon).

SIZE. Grey Partridge +; length c. 41 cm. (16 in.).

FIELD CHARACTERS. A dark-streaked sandy brown plover-like cursorial bird with thick head, long bare yellowish 'thick-kneed' legs, and huge yellow 'goggle' eyes. At rest a broad buffy bar on the closed wings, and in flight two narrow white bars and a conspicuous white patch in the dark wings are suggestive pointers. Sexes alike.

Young (immature). Paler than adult, more marked with buff and with the streaks on the underparts narrower. White wing markings less distinct.

For downy chick see Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident, with some local movements. All India (including Assam and Manipur), both Pakistans, Nepal, Ceylon — plains and up to c. 1000 m. in the Himalayas and peninsular hills; low-country Dry zone in Ceylon. Restricted to deciduous biotope. Affects stony hillsides and hummocks with sparse dhāk (*Butea*) and thorn scrub, light forest, dry riverain tracts and tank beds with babool and tamarisk jungle, mango topes and orchards, and groves of trees around villages

vanishing miraculously into the background. Brooded and tended by both parents.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit. The race *indicus* is darker and, on an average, smaller than *harterti* of the arid portions of NW. India and W. Pakistan.

Chick (in down). Forehead, crown, back and wings sandy grey speckled with black; centre of crown with two longitudinal black lines; a broad black band behind eye round the nape; cheeks, chin, sides of head and underparts buffy white, more buff on breast and with a black patch on its upper portion; two broad black lines along each side of ridge of back; two lateral black bars from base of wings to tail-tuft. 'Iris brown; bill and legs dusky pink' (Ingilis).

MEASUREMENTS. Specimens from peninsular India and Ceylon give

	Wing	Bill (from skull)	Tarsus	Tail
5 ♂♂	205-220	41-46	81-85	105-108 mm.
6 ♀♀	197-217	43-46	76-85	91-108 mm. (SA, HW)

COLOURS OF BARE PARTS. Iris yellow; eyelid yellow. Bill: base yellow, remainder black. Legs and feet greenish yellow.

MISCELLANEOUS. An observation recorded by a competent naturalist (Macdonald, A. St. J., 1950, *JBNHS* 49: 556) suggests that not only does the Stone Curlew lose its scent during the breeding season, like many other ground-nesting birds, as a protection against predators that follow their nose, but on the other hand may actually develop an obnoxious scent or taste to deter its enemies further. This observer ate a breeding Stone Curlew — excellent fare in other seasons — which his trained dog had failed to nose out and retrieve, and found it to taste 'like a pigeon boiled in quinine'! This poses an interesting problem for experimentation.

The aboriginal Murias of Bastar district (M.P.) have discovered that a Stone Curlew will not cross a mound or ridge of wood ashes though it will readily cross one of earth. They snare the bird by throwing a low ridge of ashes across the bird's accustomed path and thus diverting it along to a gap in which a horse-hair noose has been set (Kirkpatrick, K. M., 1954, *JBNHS* 52: 299).

Genus ESACUS Lesson

Esacus Lesson, 1831, *Traité d'Orn.*, livr. 7: 547. Type, by monotypy, *Oedienemus recurvirostris* Cuvier

Orthorhamphus Salvadori, 1874, *Ucc. Borneo*, in *Ann. Mus. Civ. Genova* 5: 312. Type, by monotypy, *Oedienemus magnirostris* Vieillot

Distinguished from *Burhinus* by its much more massive bill, which is compressed and nearly twice the length of the middle toe without claw.

ESACUS MAGNIROSTRIS (Vieillot)

Key to the Subspecies

- Culmen curving strongly upwards.....*E. m. recurvirostris*
- Culmen straight or almost so.....*E. m. magnirostris*

437. Great Stone Plover. *Esacus magnirostris recurvirostris* (Cuvier)

Oedicnemus recurvirostris Cuvier, 1829, Règne Anim., ed. 2, 1: 500, note 2
(No locality = Nepal, *cf.* Baker)
Baker, FBI No. 2049, Vol. 6: 80
Plate 39, fig. 15 and Plate 42, fig. 12

LOCAL NAMES. *Bāda kārūnāk* (Hindi); *Abi* (falcons); *Gānga tilāi* = Ganges lapwing, *Bāda shilabātān* (Bengal); *Baligura* (Miris of plains, Assam).

SIZE. Domestic hen; length c. 51 cm. (20 in.).

FIELD CHARACTERS. A leggy thick-headed, massive-billed plover — a larger edition of the Stone Curlew but more or less uniform greyish sandy above, white below. The distinctly upturned-looking black and yellow bill, enormous yellowish 'goggle' eyes, with white spectacle-marking

× c. 1

around them and two blackish bands above and below, are leading pointers, as is also a blackish lateral band near shoulder of closed wing. Sexes alike. In flight the peculiar arched profile of the back and a round white patch flashing on the black wing-quills are additional clues. Distant flight silhouette strikingly duck-like.

For downy chick see Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Mainly resident but with some local migratory (?) movements — all India (including Assam and Manipur), both Pakistans, Nepal, Ceylon (low-country Dry zone). Essentially riverain, affecting rocky beds of the larger rivers and their barren environs in deciduous biotope; occasionally sea beaches, tidal estuaries and salt-pans.

Extralimital. Burma, central Vietnam (Annam), and Hainan Island.

LOCAL MIGRATION? Regular seasonal appearances and disappearances as reported from certain areas unexplained and needing study. In Manipur appears regularly every year in August (earliest 29 July) and only stays until September, frequenting only particular grazing grounds and not others seemingly equally suitable. Never observed on 'return migration' (Higgins, 1934, JBNHS 37: 83). On Rameswaram Island (South India) present and fairly common except in certain months, with a marked influx during October to December (Biddulph, 1938, JBNHS 40: 250).

GENERAL HABITS. Like the Stone Curlew, also largely crepuscular and nocturnal, but distinctly not so shade-loving. Spends the day drowsing in the full glare of the sun on some baking hot sheet rock on a river bank or islet. Usually keeps in pairs or small parties of 4 to 5; occasionally loose flocks of up to 20 or so. Actions and behaviour very like 436. It is a fast

STONE CURLEWS, THICK-KNEES

7

Cinque, North Button, Little Button, etc. Not in the Nicobars. Affects muddy and sandy seashores.

Extralimital. 'The greater part of the Indo-Australasian region from the Andaman Is. and the coasts of the Malay Peninsula, Philippines, Borneo and Sumatra, east to the Bismarck Archipelago, New Guinea, Solomon Is., New Caledonia and Australia' (Peters).

GENERAL HABITS. Very little recorded in our limits. Evidently similar to the Indian race *recurvirostris* except that it is exclusively maritime. Keeps to reefs and sandy beaches in pairs or small parties, sometimes in association with Crab Plovers (*Dromas ardeola*).

FOOD. Crabs and shellfish.

VOICE AND CALLS. 'An eerie double syllable, unique and unmistakable' (Cairns). 'A mournful wee-loo harsh in tone' (Condon & McGill).

BREEDING. Season in the Andamans (Little Cocos, near Port Blair, Cinque I.), March and April — so far as known. Nest, a hollow scratched on the seashore just above high-water mark either in shingle or sand or among flotsam washed up by the tides. Eggs, 1 or 2, creamy white irregularly streaked, spotted and blotched with black or brownish black, with secondary markings of inky grey. Average size of 15 eggs 63.7 × 45.0 mm. (Baker). Share of the sexes and incubation period not recorded.

MUSEUM DIAGNOSIS. Bill differs from 437 in being much broader and deeper with the culmen almost straight instead of strongly upcurved. For description of plumage see Baker, loc. cit.; for fuller details Hume, 1874, SF 2: 291-2.

MEASUREMENTS

Wing	Bill (from feathers)	Tarsus
♂ ♀ 266-277	76-82	80-84 mm. (Baker)

'Average weight 2 lb. 4 oz.' (c. 1025 gm.) — Hume.

COLOURS OF BARE PARTS. Iris and orbital skin chrome yellow. Bill black, yellowish at extreme base. Legs and feet yellow, greenish yellow or greyish yellow; claws black.

Family GLAREOLIDAE: Coursers (Courier Plovers), Pratincoles.

For morphology and other details see Stresemann, E., 1927-34, *Aves*: 776; Baker, E. C. S., 1929, FBI 6: 84; Van Tyne, J., & Berger, A. J., 1959: 446; Pitman, C. R. S., 1964, Article 'Pratincole' in Thomson, A. L. (ed.), *New Dict. Birds*, London and New York.

CHARADRIIFORMES

6

runner and can swim creditably on occasion, riding the water high like a duck.

FOOD. Mainly crabs, the heavy bill being well adapted for prising up stones to procure them from underneath. Doubtless also eats frogs, molluscs, insects and other small animals lurking in such places. Has been observed to rob the nest of a Kentish Plover, swallowing the eggs entire (Dharmakumarsinhji, 1949, JBNHS 48: 809).

VOICE AND CALLS. 'A loud harsh single note; a low hiss when angry or frightened' (Baker). 'A loud creaking note not at all like the "curlew" call of the common Stone Plover' (Bets). 'Wild wailing cries *kree-kree-kree* *k're-k're-k're-k're*' (Phillips).

BREEDING. Season, February to June, chiefly to mid April; in Ceylon January to August, chiefly during April to July. Nest, a shallow scrape on an exposed sandbank in a river bed, unsheltered by bush or clod. Eggs frequently laid on bare sheet rock. More or less the same site is occupied year after year if undisturbed. Eggs, 2 — very like those of the Stone Curlew in shape, coloration and markings, only larger. Average size of 60 eggs 54.4 × 41.0 mm. (Baker). As in Stone Curlew, both sexes incubate and tend the young. Incubation period undetermined.

MUSEUM DIAGNOSIS. For description of plumage see Baker, loc. cit.

Chick (in down). 'Covered with close "furry" down. Narrow frontal band and line to eye, under eye and thence to occiput black; broken black lines on each side of spine, meeting at level of thighs and sending transverse bar to base of wings, black; short black line over thighs; rest of upperparts "pepper and salt" colour, finely dotted with black. Underparts white' (Ticehurst). For a more detailed description see Whistler, H., 1912, JBNHS 21: 1074.

MEASUREMENTS

Wing	Bill (from feathers)	Tarsus
♂ ♀ 252-273	74-87	c. 80-84 mm. (Baker)

Tail c. 112 mm. (SA). 'Average weight 1 lb. 12 oz.' (= c. 790 gm.) — Hume.

COLOURS OF BARE PARTS. Iris lemon yellow. Bill: sides at base including gape and base of lower mandible bright chrome yellow; entire culmen and rest of bill black. Legs and feet greenish grey; claws black.

438. Australian Stone Plover. *Esacus magnirostris magnirostris* (Vieillot)

Oedicnemus magnirostris Vieillot, 'Geoffroy St. Hilaire' = Vieillot, 1818, Nouv. Dict. Hist. Nat. 23: 231. (No locality = Australia, 1819, ex pl. G 39, f. 1, 28)
Baker, FBI No. 2050, Vol. 6: 81

LOCAL NAMES. None recorded.

SIZE. Domestic hen; length c. 57 cm. (22½ in.).

FIELD CHARACTERS. Larger than 437; readily distinguished from it by the comparatively enormous straighter bill and much more contrasty black and white markings on the head. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Andaman Islands: recorded on almost every island — Little Cocos, North Bolton, Niell, Sir Hugh Rose,

CHARADRIIFORMES

1799, 1800, 1801, or *Macrotarsus* Link, 1795. See also *Macrotarsus bitorquatus* Blyth, 1849, Jour. As. Soc. Bengal 18: 260.

Rhinoptilus Strickland, 1852 (1850), Proc. Zool. Soc. London: 220. New name for *Macrotarsus* (sic) of Blyth, preoccupied by *Macrotarsus* Lacépède, in error (Blyth, tom. cit. supra, spelt his name *Macrotarsius*). Type, by subsequent designation, *Cursorius chalcopterus*. (Sharpe, 1896, Cat. Bds. Brit. Mus. 24: 43, error, an invalid designation under Art. 30, Rule (f), International Rules of Zoological Nomenclature.)

Bill rather long, slender, and slightly arched. Tarsus and bare tibia slender, shielded in front and behind. No hind toe; anterior toes short, middle toe longer than the lateral ones with its claw expanded internally or slightly pectinated. Wings long and pointed. Tail short and almost even.

Key to the Species

	Page
A Bill straight; breast with two transverse bands <i>C. bitorquatus</i>	11
B Bill rather long, narrow and slightly curved downward; no pectoral bands 1	
1 Crown rufous in front, grey behind (adult); or, if lacking, breast cream coloured (imm.) <i>C. cursor</i>	8
Crown chestnut throughout with small black nuchal spot (adult); or, if lacking, breast dull rufous (imm.) <i>C. coromandelicus</i>	9

439. Creamcoloured or Desert Courser. *Cursorius cursor cursor* (Latham)

Charadrius Cursor Latham, 1787, Gen. Syn. Bds., Suppl. 1: 293 (Kent)
Baker, FBI No. 2051, Vol. 6: 85

Plate 38, fig. 1 and Plate 41, fig. 17

LOCAL NAMES. *Askalo* (Brahui, Baluchistan); *Chāina bori* (Kutch).

SIZE. Grey Partridge —; length c. 23 cm. (9 in.).

FIELD CHARACTERS. A sandy buff lapwing-like cursorial bird of semi-desert country with longish bare white legs and slender, slightly arching black bill. The rufous and ashy grey crown with a broad black and white stripe from behind eye to nape, and black edging to the closed wings (primaries) are leading pointers. Sexes alike.

On the ground, colour scheme and general effect remarkably like an enlarged edition of the Desert Lark (*Alaemon alaudipes*) which shares its barren habitat. In flight, the black lining of the narrow pointed wings is a striking feature.

Young (immature). Paler duller sandy with the upperparts wavyly barred with blackish brown. No rufous or grey in the crown.

STATUS, DISTRIBUTION AND HABITAT. Winter visitor (August to April) to the arid portions of W. Pakistan (Baluchistan, Sind, Punjab), and NW. India — Rajasthan (SE. to about Ajmer) and Gujarat (Banāskāntha, Kutch, Saurashtra). Affects semi-desert and desert country — sunbaked *pāts* with sparse *Salvola* and *Suaeda* bushes, or dotted with *Capparis* and hummocks of wind-blown sand. Also sandy fallow fields on the desert edge.

Extralimital. 'Breeds in N. Africa from Morocco to the Red Sea, Palestine eastward through Mesopotamia (Iraq) to S. and W. Persia, perhaps farther. In winter occurring as far S. as Lake Chad and Somaliland and extending to NW. India. Occasional in Europe north to the British Isles and Germany' (Peters).

MIGRATION. No ringing or other precise data.
GENERAL HABITS. Similar to Indian Courser (440), q.v., with which it sometimes associates where their habitats overlap. Keeps in loose scattered parties of 6 to 10 birds, occasionally up to 30 or more. Flight and wing action closely resembles pratincoles'.

FOOD. Chiefly insects — caterpillars, beetles, ants, locusts, etc.
VOICE AND CALLS. Very silent. Occasionally a low clucking note on the wing somewhat like that of the Common Sandpiper.

BREEDING. Extralimital, but some suggestive circumstantial evidence of nesting, sporadically (?) in Bahawalpur and Kutch.

MUSEUM DIAGNOSIS. For description of plumage see Baker, loc. cit.

MEASUREMENTS			
Wing	Bill (from skull)	Tarsus	Tail
4 ♂♂ 160-171	50-52	52-60	63-68 mm.
4 ♀♀ 162-166	29-33	55-57	64-66 mm. (SA)

Hartert (Vög. Pal. Fauna 2: 1524) gives as follows:
♂♂ 153-166 30-32.5 56-60 61-64 mm.
(mostly 158-164)

COLOURS OF BARE PARTS. Iris brown. Bill black. Legs and feet creamy white or fleshy white.

440. Indian Courser. *Cursorius coromandelicus* (Gmelin)

Charadrius coromandelicus Gmelin, 1789, Syst. Nat., 1 (2): 692 (Coromandel Coast) Baker, FBI No. 2052, Vol. 6: 85
Plate 38, fig. 2 and Plate 41, fig. 18

LOCAL NAMES. Nibri (Hindi); Thirath (Mirahikars, Bihar); Terā chikurā (Telugu); Wili kirāla (Sinhala); Al katti (Tamil, Ceylon); Vili ālāppin (Malayalam).
SIZE. Grey Partridge — ; length c. 26 cm. (10 in.).

FIELD CHARACTERS. A sandy brown lapwing-like cursorial bird with chestnut and black underparts, slender slightly arching black bill, and long bare china-white legs. The rich rufous crown with a conspicuous double black and white stripe through and above eye to nape are diagnostic. Sexes alike. In flight reminiscent of pratincole, the dark undersides of the narrow pointed wings heightening the resemblance.

× 1/2

Young (immature). Above, dull buff irregularly barred with blackish brown. A small pale supercilium but no black stripe

No size difference between the sexes, but birds from Ceylon clinally somewhat smaller than from peninsular India.

COLOURS OF BARE PARTS. Iris dark brown or hazel. Bill black. Legs and feet china-white or ivory white.

441. Jerdon's or Doublebanded Courser. *Cursorius bitorquatus* (Blyth)

Macrotarsius bitorquatus 'Jerdon' = Blyth, 1848, Jour. As. Soc. Bengal 17: 254 (Eastern Ghats of the peninsula of India)
Baker, FBI No. 2053, Vol. 6: 88
Plate 38, fig. 3

LOCAL NAMES. Adiri ālā-kitti = 'Jungle empty-purse' (Telugu) recorded by Jerdon, enigmatical and not locally current or understood!

SIZE. More or less same as Indian Courser (440); length c. 27 cm. (10½ in.).

FIELD CHARACTERS. An obvious close relation of the Indian Courser. Above: Crown and hindneck dark brown with broad whitish supercilia from lores looping round nape; rest of upper plumage pinkish sandy brown. Below: chin and throat whitish; foreneck rufous, separated from brown breast by a white band; a second white band across lower breast; rest of underparts whitish. Tail white and black. A white wing-bar prominent in flight. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Present status unknown; ostensibly extinct. Believed by Jerdon (c. 1864) to be a permanent resident apparently with an extremely limited range. Recorded rarely since first described in 1848 and only from the Penner and Godavari valleys in Andhra — Nellore, Cuddapah, Sironcha, Bhadrachalam, and Anantapur neighbourhoods. Last authentic record in 1900, since when thorough search by competent ornithologists has failed to rediscover it in the same localities or elsewhere. Unlike Indian Courser was found on rocky undulating ground with thin forest and scrub jungle, not in open waste land.

GENERAL HABITS, FOOD, VOICE AND CALLS. 'Was found in small parties, not very noisy, but occasionally uttering a plaintive cry' (Jerdon). Blanford met pairs twice and three birds together once (1857 and 1871) and describes the flight as more rapid than Indian Courser's.

BREEDING. A clutch of 2 eggs claimed to have been taken by an anonymous writer in the defunct Asias newspaper in 1895. They were described as bright yellow-stone, the ground colour almost obliterated by black scrawly blotch-and-spots; laid on the ground in thin scrub jungle. No authentic information available. Two males collected by Blanford on 5 and 8 March (1871) near Bhadrachalam showed no gonadal development.

MUSEUM DIAGNOSIS. Wing rather less pointed than in Indian Courser; 2nd and 3rd primaries (as) longest and subequal. Bill smaller, straight and rather broader at base than in 440. For description of plumage see Baker, loc. cit.

MEASUREMENTS			
Wing	Bill (from feathers)	Tarsus	Tail
♂♀ 161-168	18-19	68	64-65 mm. (Baker)

below it. Below, chin and abdomen white; breast dull rufous, more or less barred with blackish.

For downy chick see Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident. Common but rather patchily distributed everywhere; also partly nomadic and/or locally migratory (?) — W. Pakistan (Baluchistan, Sind, Punjab), all India (excepting Assam and Manipur), E. Pakistan, Nepal, etc. In Ceylon resident in the low-country Dry zone, chiefly around Jaffna Peninsula. Affects dry stony plains and Deccan plateau country — waste and fallow land with scattered scrub, ploughed fields, and village grazing grounds. Avoids areas of heavy rainfall as well as pure desert, but associates with Cream-coloured Courser (439) at the seam of its desert habitat.

LOCAL MOVEMENTS. No ringing or other precise data.

GENERAL HABITS. Terrestrial and cursorial. Keeps in pairs or scattered parties and small flocks in open country, where its coloration is astonishingly obliterative as long as the bird remains still. Runs about swiftly in short spurts dipping forward obliquely every now and again in characteristic plover style to pick some insect. When alarmed or suspicious the bird spurts forward a few metres, halting abruptly every little while to pull itself erect for a good look at the intruder before making the next spurt, and so on, quickly increasing the distance between itself and the object of its suspicion. If further pressed, rises with a peculiar note and flies fairly low along the ground for maybe fifty or a hundred metres, resuming its spurts immediately upon touching down. When thoroughly disturbed, rises higher in the air with deliberate rapid wing-strokes, then showing a considerable turn of speed. The narrow pointed dark-lined wings and flight silhouette are distinctly like a pratincole's.

FOOD. Chiefly insects — beetles and their larvae, grasshoppers, crickets, etc.

VOICE AND CALLS. Very silent. A low clucking note on flushing.

BREEDING. Season overall March to August, the most favoured months varying locally; in Ceylon mainly May. Nest, a shallow unlined scrape on the bare soil on arid fallow or waste land. Eggs, 2 or 3, pale yellowish stone-colour to rich yellow-buff, thickly spotted and blotched with black; with minor variations. They are smooth-surfaced, broad blunt ovals. Incubation and tending of chicks largely by female, but male also assists. Period of incubation undetermined. Unlike lapwings, the parents do not demonstrate when nest approached or chicks handled. Both eggs and downy chicks remarkably camouflaged, merging perfectly into their surroundings and becoming completely lost even at a couple of metres' distance the instant the observer takes his eyes off them.

MUSEUM DIAGNOSIS. For description of plumage see Baker, loc. cit.

Chick (in down). 'Whole head, wings and upperparts mottled ginger, creamy white and black with no definite pattern. Underparts creamy white, pectoral region ginger; legs greyish' (Ticehurst).

MEASUREMENTS			
Wing	Bill (from skull)	Tarsus	Tail
♂♀ 143-163	23-30	49-57	45-64 mm. (SA, HW)

COLOURS OF BARE PARTS. Iris umber brown. Bill blackish at tip of both mandibles, pale yellow at gape and base as far as nostrils. Legs and feet pale yellowish white with a fleshy tinge; soles flesh-coloured; claws horny (Blanford).

Genus GLAREOLA Brisson

Glareola Brisson, 1760, Orn. 1: 48; 5: 141. Type, by tautonymy, *Glareola* Brisson = *Hirundo pratincola* Linnaeus

Bill short, wide and rather high at base; culmen curved; gape very large. Wing long and narrow: first primary (as.) longest; closed wings reaching to tip of or beyond tail. Tarsus short, scutellated in front and behind; hind toe well developed and raised above the anterior toes at base; lateral toes short; outer and middle toes united by a small web. Claws long, that of middle toe pectinated on inner margin.

442. Collared Pratincole or Swallow-Plover. *Glareola pratincola* (Linnaeus)

Hirundo Pratincola Linnaeus, 1766, Syst. Nat., ed. 12, 1: 345 (Shores of southern Europe and in Austria; restricted type locality, Austria, BOU Committee)
Baker, FBI No. 2054, Vol. 6: 89
Plate 44, fig. 2

LOCAL NAMES. None recorded.

SIZE. Myna ±; slimmer. Length c. 23 cm. (9 in.).

FIELD CHARACTERS. A short-legged plover, shaped like a tern, with long narrow, pointed wings extending when closed to tip of deeply forked tail. Above, head and back olive-brown; lores black continued under eye as a narrow black band or gorget looping round throat patch. Upper tail-coverts white; tail black with white base. Below, chin and throat pale rufous-buff bounded by the black loop (reminiscent of Grey Partridge). Upper breast brown, passing downwards into rufous and then to white on abdomen and under tail-coverts. Narrow pointed wings, chestnut underwing lining, and black wing-quills conspicuous in flight. Sexes alike.

Young (immature). Above olive-brown stippled with fulvous and black. Below, no black gorget; breast mottled brown and rufous-white.

STATUS, DISTRIBUTION AND HABITAT. Breeds sparingly in W. Pakistan; straggles into India and Ceylon in winter. Specimens taken at Allahabad

¹Vaurie (1953) treats *G. pratincola* and *G. maldivorum* as full species.

COURSERS, PRATINCOLES

13

in the east, Ahmedabad, Ratnagiri, and Coimbatore in the south, and in Hambantota district (Southern Province), Ceylon. Possibly more common and regular than the records indicate, but undifferentiated from the resident *maldivarum* (443). Affects barren sun-scorched flood plains by rivers and tidal creeks, and grazing land bordering jheels, etc.

Extralimital. 'Breeds in the countries adjacent to and islands in the Mediterranean and Black Seas, eastward through Mesopotamia (Iraq) and S. Persia to NW. India; also from the Caspian Sea to Turkestan. Partly resident, but birds from the northern part of the breeding range winter in Africa north of the Sahara' (Peters).

GENERAL HABITS, FOOD, VOICE AND CALLS. As in the Indian race (443), q.v.

BREEDING. Breeds colonially in West Pakistan, in Baluchistan and Sind (Sonmiani in Las Bela, and Jungshahi, both within 100 km. of Karachi). *Season*, March, April, May. Nest and eggs as in 443. Average size of 40 eggs taken in W. Pakistan 30.5 × 23.4 mm. (Baker). Both sexes share incubation; period recorded elsewhere as about 18 days. When young are hatched, adult birds remarkably demonstrative, flying round very close to the intruder, constantly uttering their tern-like cry *chitti, chitti*, then settling at a few paces to do the well-known 'wounded' antics — lying with wings outspread and falling over on their sides (Ticehurst). C. R. S. Pitman describes the curious effect produced by one such colony of fluttering birds in mass distraction display as 'of a snake coiling about or a big lizard moving along'.

Downy chicks fed by regurgitation. They run very swiftly and are adept at hiding in hoof-prints, etc. and vanishing from sight.

MUSEUM DIAGNOSIS. Differs from *maldivarum* by shape and colour pattern of tail (see sketch): in *pratincola* outermost tail-feather over 20 mm. longer than the next; in *maldivarum* under 15 mm. See also Key to the Subspecies. Tips of secondaries

generally white; throat and lower breast less strongly suffused with rufous. For description of plumage see Baker, loc. cit.

Chick (in down). 'Head, wings and back grizzled dark brown and pale buff with median dark line down crown; underparts pale buff' (Ticehurst).

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail

♂♀	176-200	15-16	30-32	54-58	102-119 mm.

(Baker)

COLOURS OF BARE PARTS. As in 443.

COURSERS, PRATINCOLES

15

BREEDING. In addition to the known breeding localities (see Status) also said to breed in the Andamans (where normally a summer immigrant), but not yet proven. *Season*, overall April through June. *Nests*, colonial: a shallow scrape, or not even that, on hard sunbaked grassland or stubble fields preferably where recently burnt, where the eggs become remarkably invisible. Eggs sometimes laid in deepish hoof-prints of cattle. The same sites often used year after year. *Eggs*, 2 or 3, pale yellowish stone to rich yellow buff, densely spotted and blotched with black and with grey secondary markings. In coloration and shape very similar to eggs of Indian Courser (440) with the same range of variations. Average size of 60 eggs 30.8 × 23.9 mm. (Baker). Behaviour at nest, etc. not different from 442, q.v.

MUSEUM DIAGNOSIS. For distinguishing from 442 see Key to the Subspecies and remarks under that form.

Young (immature). For description, not in FBI, see Lapersonne, JBNHS 35: 686.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail	
				central	outer
♂♀	173-191	13-15	30-33	52-62	71-85 mm.

(Baker)

COLOURS OF BARE PARTS. Iris dark brown, bill black, reddish at gape brighter in breeding season. Legs and feet dusky black.

444. Small Indian Pratincole or Swallow-Plover. *Glareola lactea* Temminck

Glareola lactea Temminck, 1820, Man. d'Orn., ed. 2: 503 (Bengal)

Baker, FBI No. 2056, Vol. 6: 92

Plate 38, fig. 5 and Plate 44, fig. 4

LOCAL NAMES. *Utteran* (Sind); *Chhāṣṭā bābūibāṭān* (Bengal).

SIZE. Sparrow+; length c. 17 cm. (6½ in.).

FIELD CHARACTERS. A sandy grey fruiatile bird with pointed, swallow-like wings and slightly forked tail.

In overhead flight the whitish underparts, black wing lining (axillaries and coverts) contrasting with white bases of the quills, and black-tipped squarish white tail, are suggestive clues. In fading twilight, silhouette and actions in the air strongly reminiscent of pipistrelle bat.

Adult. Above pale sandy grey. Forehead brown; a band from eye to bill black. Tail-coverts and base of tail white, blackish towards end. Below, sooty brown tinged with rufous, becoming white from lower breast downwards. Sexes alike.

Young (immature). Feathers of upperparts obsoletely edged paler sandy or buff, producing a somewhat scaled effect. Throat and foreneck spotted with blackish.

STATUS, DISTRIBUTION AND HABITAT. Resident, nomadic (?), and local migrant. West Pakistan (westward limit Indus river), all India (including Kashmir and Assam), Nepal (terai and up to c. 750 m.), E. Pakistan, and

14

CHARADRIIFORMES

443. Large Indian Pratincole or Swallow-Plover. *Glareola pratincola maldivarum* J. R. Forster

Glareola (Pratincola) Maldivarum J. R. Forster, 1795, Faunula Indica, ed. 2: 11 (Open sea in the latitude of the Maldive Islands, ex Latham, Gen. Syn. 5: 224, vr. B)

Baker, FBI No. 2055, Vol. 6: 90

Plate 38, fig. 4 and Plate 44, fig. 3

LOCAL NAMES. *Bēḍā bābūibāṭān* (Bengal); *Abularg?* (Maldive Is.).

SIZE. Myna ±; slimmer. Length c. 24 cm. (9½ in.).

FIELD CHARACTERS. As for 442 but tail less deeply forked. Difference imperceptible except in the hand. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Not clear: variously resident, summer visitor, nomadic and/or locally (?) migratory. Known to breed in

× c. ½

W. Pakistan (Sind), Madhya Pradesh, near Delhi (JBNHS 65: 780), W. Bengal (near Calcutta—Biswas), Assam, E. Pakistan, and Ceylon, straggling erratically chiefly in winter more or less throughout India; E. Pakistan, Nepal, Ceylon, Andaman, Nicobar, Cocos and Maldive Is. Breeds in company with nominate *pratincola* at the seam or meeting ground of their breeding ranges in Sind, both forms being summer visitors

to the district from east and west respectively. 'The former (*pratincola*) does not breed eastwards of this district, nor the latter (*maldivarum*) west of it' (Ticehurst). Affects dried-up flood plains by large rivers, tidal mudflats and marshes, paddy stubbles in coastal areas, ploughed and fallow fields, open grazing grounds, etc.

Extralimital. 'Breeds from the upper Argun River in Transbaikalia, N.E. Mongolia and S. Manchuria, south to India, Ceylon, Burma, Siam, Indochina, and Hainan. On migration or in winter through the Malay Archipelago to Australia' (Peters).

GENERAL HABITS. Gregarious, and inclined to be somewhat crepuscular. Keeps in flocks of 30 or 40 — sometimes very large ones of several hundred. Most active in the mornings and evenings — also in cloudy overcast weather — flying about high up in the air like swallows, wheeling and twisting and in swift zigzags, hawking insects with their capacious gapes — occasionally descending to treetop height or even skimming over cultivated fields and grassland. To a lesser extent also feeds on the ground, running about like a courser. The birds are sluggish during daytime, spending the hot hours squatting or standing about in the scorching sun on some open sandbank in a river or on pasture land.

FOOD. Flying insects, principally moths (Heterocera), beetles (Coleoptera), bugs (Hemiptera) and winged termites (Termitidae). Also 'Water-boattmen' (Corixidae and Notonectidae) which must evidently fly high in sunshine. Baker noted 'a curious habit of scratching in the soil rather like a small game bird, both when feeding and when dusting'.

VOICE AND CALLS. Constantly utters a characteristic *kirri-kirri* in flight (Deignan). Cf. 442 under 'Breeding'.

16

CHARADRIIFORMES

Ceylon (low-country Dry zone). Affects large placid streams with sandbars, following the northern ones into the Himalayas up to c. 1800 metres. Also large jheels and coastal swamps (e.g. the Sunderbans, where reported to be extraordinarily common and abundant).

LOCAL MOVEMENTS. No ringing or other precise data. Found in many breeding localities only between April and August, disappearing thereafter.

GENERAL HABITS. Gregarious. More partial to water than its larger relatives. Keeps in flocks in the neighbourhood of large tanks and rivers — sometimes immense and of almost swarm proportions. Rather crepuscular, hawking into the dusk till almost quite dark. Winged insects captured high up in the air or scooped up from near the ground or water surface. After a bout of dashing and zigzagging to and fro the birds descend to settle on a sandbank in a scattered crowd, individuals darting about in spite to feed in the characteristic plover manner. From time to time the flock rises simultaneously as to a given signal, to resume hawking. Flight rather 'angular', very reminiscent of a pipistrelle's, with the same agile turning, twisting, abrupt stopping short and doubling in pursuit of prey. In the gloaming when pratincoles, swifts and the small insectivorous bats are all flying around together high up in the air as is common, indeed any one of them may casually be mistaken for the other.

FOOD. Insects, chiefly flying beetles (Coleoptera), bugs (Hemiptera) and termites (Neuroptera).

VOICE AND CALLS. Some notes reminiscent of the *tuck-tuck-tuck* calls of the House Gecko (*Hemidactylus*). 'Others [notes] made me feel I was listening to a greenfinch' (Lowther, from photographing hide). When disturbed at nest colony and flying about agitatedly overhead, *tiriri, tiriri, tiriri*, etc.

BREEDING. *Season*, in India overall February through April; in Ceylon March, April. Second layings later, even up till June if first clutches washed away by floods due to melting snows or unseasonable rain. *Nests* colonial, often several scores close to one another — shallow scrapes or none at all on exposed sandbanks in placid rivers, often down to the water's edge; frequently in company with terns and skimmers. *Eggs*, normal clutch 2 exceptionally 3. In eastern India *ride* Baker, 3 most usual, 2 exceptional; in Assam clutches of 4 normal. Ground colour of eggs mostly pale sandy buff or sandy grey with small spots and blotches of light grey-brown or reddish brown and secondary blotches of lavender or neutral tint. Minor variations common. Shape broad oval, very little compressed at smaller end. Average size of 200 eggs 25.9 × 20.5 mm. (Baker). Both sexes take part in incubation; period unrecorded. The eggs as well as downy chicks are admirably camouflaged and merge into their sandy environment in an astonishing way. Nesting birds, flying around and agitatedly diving at

SKUAS, JAEGER

17

intruder, have a curious habit of alighting, singly or several at a time, squatting in front of him, opening wings and shuffling as if settling on eggs or chicks. When further approached they scuttle away dragging one wing or beating it on the sand as if broken, again shuffling and making as if to settle on eggs a little further on, and repeating the broken-wing tactics when further approached, finally taking to the air at the water's edge and joining their companions overhead.

MUSEUM DIAGNOSIS. See Key to the Species; for description of plumage Baker, loc. cit.

Chick (in down). 'Whole of upperparts finely mottled greyish white, dusky, and pale buff; narrow black line behind eyes; underparts white' (Ticehurst).

MEASUREMENTS

Genus CATHARACTA Brünnich

Catharacta Brünnich, 1764, Orn. Boreal.: 32. Type, by subsequent designation, *Catharacta skua* Brünnich

Cf. Witherby, Handbook of British Birds, 1947, 5: 122; Ibis, 1956, 98: 161.
Contains large pelagic gull-like birds with webbed feet, of brown or squamated plumage, paler or darker in shade, resembling the immature plumage of certain gulls, and also some shearwaters (Procellariidae). Bill differs from gulls' in being broader at base with culmen greatly curved at tip which is bent over the lower mandible. Cere extends more than half culmen, the anterior lower portion overhanging the nostril (cf. shearwaters which have tubular nostrils). Lower mandible nearly straight, the angle being near the tip. Tarsi long and strong, scutellated in front reticulated behind; anterior toes long and fully webbed; hind toe small; claws small but curved and sharp. Wing long and pointed: 1st primary (as.) longest. Tail rounded with middle rectrices slightly elongated and projecting beyond the others.

Skuas are predatory on the eggs and chicks of terns, penguins, and other colonial-nesting sea birds. But they also live largely by piracy, attacking and chasing gulls and other birds savagely and with determination, forcing them to surrender their lawful prize and then deftly retrieving the spoils in mid-air. The birds breed in the

22

CHARADRIIFORMES

STATUS. Not very uncommon along the Makran coast (W. Pakistan) where Hume met with it at sea off Ormara, Gwadar, Pasni, etc. from middle to end February. Butler saw about a dozen between Pasni and Gwadar 13-17 May, and W. W. A. Phillips observed one — *presumably* this species — in the Arabian Sea at c. 24°47'N., 66°32'E. as late as early July (1946, JBNHS 46: 612). Five examples sighted, Bombay (Sinclair, J. C., 1976, JBNHS 73: 530).

Dr C. B. Ticehurst quotes an interesting observation on the parasitic habits of what was probably this skua recorded by a Portuguese mariner, one Pedro Taxeira, early in the year 1604 off the coast of Oman. He writes that he 'saw certain birds chasing others from natural enmity. The weaker soar upward to escape from the stronger, and in terror void the contents of their stomachs. The bird below hunting the others to this end or from natural spite as fast as this happens, opens his beak, catches the same droppings and eats them. I have it from natives that on this matter he subsists.'

DISTRIBUTION. Breeds on the Arctic coasts and islands of the Holarctic Region. (For details see Peters, 1934, 2: 311.)

MUSEUM DIAGNOSIS. See Key.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Mid toe without claw	Tail

449. Sooty Gull. *Larus hemprichii* Bruch

Larus (*Adelarus*) *Hemprichii* 'Bp.' = Bruch, 1853, Jour. f. Orn. 1: 106 (Red Sea)

New name for *Larus crassirostris* Vigors, not of Vieillot

Baker, FBI No. 2063, Vol. 6: 104

Plate 45, fig. 7

LOCAL NAMES. None recorded.

SIZE. Domestic duck —; length c. 48 cm. (19 in.).

FIELD CHARACTERS. A medium-sized sea gull with brown head and breast, white collar, and greyish brown mantle. Sexes alike.

Adult (summer). Head, nape, and throat (the 'hood') sooty brown with a short white eyebrow. Separated from greyish brown mantle and grey breast by a prominent white collar. Wing-quills blackish brown, the inner ones tipped with white. Abdomen, tail-coverts and tail white.

In winter the white collar disappears and the head and foreneck are paler brown, much mottled and streaked with white.

Young (immature). Upperparts paler and squamated with whitish; tail brownish mottled with white, with a broad brown subterminal bar.

For downy chick see Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Winter visitor to Makran and Sind coasts of West Pakistan. Common and abundant in Karachi Harbour and seaboard, withdrawing towards breeding ground in early June. Strangely enough never recorded from the Gujarat coast, but a single straggler observed at Bombay by Hume, January 1875 (1876, SF 4: 414).

Extralimital. 'Breeds on islands in the southern part of the Red Sea, on the coasts of the Gulf of Aden, and on Astola I. off coast of Persian Baluchistan [W. Pakistan]; ranges north in the Red Sea to about lat. 22°N., south on the coast of E. Africa to Zanzibar, along the Makran coast and east to Sind' (Peters).

GENERAL HABITS. Gregarious and exclusively maritime, never (?) found away from the sea coast; largely a scavenger. Frequents harbours, flying around ships at anchor for scraps and garbage, but chiefly attends on off-shore fishing boats to scavenge the fish offal cast overboard. Unlike Herring Gull does not frequent villages for this purpose. Picks up scraps floating on the water from the air or alights alongside to deal with them, riding buoyantly like a duck and taking off again effortlessly.

FOOD. Chiefly dead fish and offal. An important predator of terns' eggs and chicks in nesting colonies; also pirating on the birds in the manner of a skua.

VOICE AND CALLS. On breeding ground utters 'a peculiar mournful cry which is kept up throughout the breeding season' (E. A. Butler, 1877, SF 5: 296). For other calls see Fogden, op. cit. infra.

BREEDING. Colonial; sometimes individual. Only known locality within our area Astola or Astalu Island off the Makran coast (West Pakistan)

GULLS, TERNS

25

c. 40 km. ESE. of Pasni. Season, end June to end August. Nest, 'a slight depression with a few bents of grass and *Salvola* scrub situated at the side of and sheltered by a tuft of *Salvola*' (C. B. Ticehurst quoting Sir Percy Cox). Eggs, full clutch of 2 or 3: dull pale yellowish stone to pale purplish grey or pale brown, blotched and spotted with various shades of brown, grey, or inky purple. Average size of 24 eggs 56.8 × 40.9 mm. (Baker). Incubation period 'at least 25 days'. (For full details see M. P. L. Fogden, 1964, 'The Reproductive Behaviour and Taxonomy of Hemprich's Gull, *Larus hemprichii*'. *Ibis* 106: 299-320.)

MUSEUM DIAGNOSIS. For description of plumage see Baker, loc. cit.

Chick (in down). Pale greyish fawn, very slightly mottled darker on upperparts and with a dull pink bill tipped with black — Fogden.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	320-348	43-48	50-58	139-159 mm. (Baker)
8 ♂ ♂	340-363	48-52 mm.		
3 ♀ ♀	330-337	43.5-48 mm.		

(Ticehurst)

COLOURS OF RARE PARTS. Adult. Iris brown. Eye rim red. Bill yellow-green, black at angle, red band, yellow tip. [Cape bright red — Fogden.] Legs and feet olive-green. Immature. Eye rim black. Bill greeny-grey, black at angle, reddish tip. Legs and feet grey' (Ticehurst).

LARUS ARGENTATUS — LARUS FUSCUS

There is some difference of opinion among authorities on the taxonomic status of the large Herring and Blackbacked gulls of the *argentatus-fuscus* complex. These are two very closely related 'species' differing mainly in the coloration of the mantle, which ranges from pale blue-grey in *Larus argentatus* to almost slaty black in *L. fuscus*. The differences between adjacent populations of the two are no more than would normally pass for geographical races of a single species were not the position complicated by the fact that their breeding ranges overlap in northwestern Europe. By some authorities they are nevertheless treated as races of a single species, the anomaly of sympatry being explained away by the putative status of the two as terminal links of a circumpolar chain of races ('species ring') that have come together again after prolonged isolation from each other during which they have developed reproductive isolation and now behave like true species. The apparent absence of interbreeding between the two species is shown by Paludan, 1951, to be untrue and not due to any genetic isolation but merely to a difference in the timing of their respective physiological readiness. On certain Danish islands where both the species breed — *argentatus* usually starting a fortnight earlier than *fuscus* — Paludan found a few mixed pairs of *argentatus* with *fuscus* freely interbreeding where the timing had been synchronous. However, in view of the fluidity of opinion among ornithologists these gulls are being treated here as two polymorphic species. Racial identification of individual Indian examples, especially immature, is difficult even

¹ Paludan, Knud, 1951, 'Contributions to the breeding biology of *Larus argentatus* and *Larus fuscus*'. Copenhagen (Ejnar Munksgaard).

GULLS, TERNS

27

horizontal carriage of body. Flocks roost at night on sheltered sandbars or rocks, the birds often flying considerable distances back and forth between their feeding and roosting places around dusk and dawn. Flight strong and buoyant with leisurely wing-beats interspersed with long periods of graceful, effortless sailing, gliding and soaring — up, down, or in circles — taking full advantage of air currents and eddies.

FOOD. Fish offal, and miscellaneous refuse; molluscs, crabs, insects. Robs eggs and chicks of terns and other colonial-nesting sea birds, and to some extent also lives by piracy like skuas.

VOICE AND CALLS. One of the commonest calls a loud raucous *kee-ow*, *kee-ow*, *kee-ow*, etc. reminiscent of the Fishing Eagle *Haliaeetus leucorhynchus*, resembling the creaking of the block tackle of a fishing boat lowering its sails, or of the uncoiled wooden water-lifting pulley of a village well.

BREEDING. Extralimital. Colonial; on sea-cliffs and coastal sand dunes.

MUSEUM DIAGNOSIS. One of the darkest forms of the Herring Gull. For description of plumage see Baker, loc. cit.; for details of plumage phases, bionomics, characters, etc. of the paler-mantled and pinkish-legged but otherwise very similar nominate race, Withersby, 1941, 5: 85-95.

For an exhaustive review of the forms of the larger gulls, including *Larus argentatus* and *L. fuscus*, Stegmann, B., 1934, Jour. f. Orn. 82 (3): 340-80.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	415-450	49-63	62-77	158-180 mm.

COLOURS OF RARE PARTS. Adult. Iris white to yellow; orbital ring bright vermillion. Bill bright yellow with a vermillion patch near tip of lower mandible. Legs and feet bright yellow (Baker).

MISCELLANEOUS. Two birds (of the nominate race) ringed as flying juveniles in 1909 and 1910 were recovered when almost 25 and 26 years old (*Der Vogelzug*, July 1935, p. 135). Since then a herring gull has been recovered 31 years 11 months after ringing as chick (*The Ring* 3: 147-52, 1962).

451. Pinklegged Herring Gull. *Larus argentatus mongolicus* Sushkin

Larus argentatus mongolicus Sushkin, 1925, Bds. Russian Altai etc.: 63
(Lake Uriugnoor [= Urga Nor], NW. Mongolia)

Baker, FBI No. 2066? (part), Vol. 6: 109

SIZE. Same as 450 = domestic duck ±; length c. 60 cm. (23 in.).

FIELD CHARACTERS. Not satisfactorily distinguishable from 450; mantle slightly paler grey; legs and feet usually pinkish.

Young (immature). As 450.

STATUS, DISTRIBUTION AND HABITAT. An eastern form 'wintering as far west as the coast of Bombay and West Pakistan (Sind). In passage may occur inland on large lakes. Birds previously referred to as *cachinnans* in Indian list probably belong to this race' (SDR).

26

CHARADRIIFORMES

in the museum, and impossible in the field. Published sight records in India are vitiated by ambiguity; therefore no more than the general status of the wintering forms is attempted here.

LARUS ARGENTATUS Pontoppidan

Key to the Subspecies

Mantle paler, legs and feet pale fleshy pink or bluish.....*L. a. mongolicus*

450. Yellowlegged Herring Gull. *Larus argentatus heuglini* Bree

Larus Heuglini Bree, 1876, Bds. Eur., ed. 2, 5: 58 and pl. (New name for *Larus cachinnans* Pallas, not of Pallas, Heuglin, 1873, Orn. Nord-Ost. Afr. 2, Abth. 2, no. 892, part; type from Zeyla, Somaliland)

Larus affinis taimyrensis Buturlin, 1911, Orn. Mitt. 2: 149

(Western shores of the Gulf of Yennesei)

Baker, FBI No. 2065, Vol. 6: 107

Plate 45, fig. 8

LOCAL NAMES. Unrecorded.

SIZE. Domestic duck ±; length c. 60 cm. (23 in.).

FIELD CHARACTERS. A large, heavy gull. Adult (summer). Entire head, neck, underparts and tail snow white. Mantle slaty grey. In flight leading and trailing edges of wings white. Wing-quills chiefly black with small white 'mirror' near tip of wing. Legs and feet yellow; a bright red patch near tip of lower mandible.

In winter head and hindneck streaked with brown. Sexes alike.

Young (immature). Above, dark brown flecked with whitish; more buffy on the wings. Below, white mottled and streaked with pale brown. Tail brown, tipped with white. Legs and feet dull fleshy yellow.

STATUS, DISTRIBUTION AND HABITAT. Winters along the northern Indian Ocean coasts east to the Makran coast and south along the coast of West Pakistan and western India to Bombay, rarely to Kerala and Ceylon (SDR).¹ A pair (subspecies?) observed in Kathmandu Valley, Nepal, in November 1962 and one collected (Fleming, R. L., 1963, *Pavo* 1(2): 127). Doubtless on passage.

Affects the sea coast and harbours; inland lakes in Sind (and elsewhere?) 'only where there is a fishing industry' (Ticehurst).

Extralimital. 'Breeds in northern Siberia in the wooded and perhaps subalpine portions of the lower Yenisey, Taimyr Peninsula, and the Khatanga; non-breeders occur on the adjacent portions of the Arctic coast. Relict breeding colonies on the Baraba and Kirghiz Steppes. Winters in the southern part of the Red Sea, the north Somali coast, and in the Persian Gulf' (Peters). For fuller details see Vaurie, 1965, 2: 468-9.

GENERAL HABITS. Gregarious and largely maritime. A scavenger at seaports, harbours and fishing centres. Picks up scraps cast overboard from ships and fishing boats, and fish offal around coastal villages. Settles freely both on water and on the ground, swimming buoyantly or walking about with a

¹ But see Note, p. 25.

28

CHARADRIIFORMES

Extralimital. 'Breeds on the lakes of central Asia from southeastern Russian Altai and Dzungaria across NW. Mongolia to Lake Baikal. In winter on the coasts of China and Indochina' (Peters). See also Vaurie, 1965, 2: 472.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 450.

BREEDING. Extralimital.

MUSEUM DIAGNOSIS. Unsatisfactory without adequate comparative material. See Key; also description Stegmann, B., 1934, Jour. f. Orn. 82 (3): 376-7.

MEASUREMENTS. 46 ♂ ♀ (27 ad., 19 imm.) Wing 435-480 mm. (av. 462); tarsus 63-75 mm. (Stegmann).

COLOURS OF RARE PARTS. As in 450 except legs and feet which are chiefly pale flesh colour or bluish, but sometimes yellow!

452. Lesser Blackbacked Gull. *Larus fuscus fuscus* Linnaeus

Larus fuscus Linnaeus, 1758, Syst. Nat., ed. 10, 1: 136

(Europa, restricted type locality Sweden)

Baker, FBI No. 2065, Vol. 6: 107

Plate 45, fig. 9

LOCAL NAMES. Unrecorded.

SIZE. Same as 450 = domestic duck ±; length c. 60 cm. (23 in.).

FIELD CHARACTERS. Adult (summer). Head, neck, underparts, and tail pure white; mantle dark slaty grey, almost blackish. In flight the strongly contrasting narrow white leading and trailing edges of the dark wings, and white tips to the black primaries conspicuous. When seen together with *argentatus* difference in the mantle of the two species quite obvious. Legs yellow as in 450, but usually more orange. Sexes alike.

In winter head more heavily streaked with brown than in *argentatus*.

Young (immature). Mottled brown, indistinguishable with certainty from 450, q.v.

STATUS, DISTRIBUTION AND HABITAT. Winter visitor (August-September to April-May) to the coast of West Pakistan (Makran, Sind) and western India south to Kerala; possibly also Ceylon and up the Coromandel coast whence reported. Records of large wintering gulls of the *argentatus-fuscus* group in India badly mixed up and ambiguous as to species. Position needs clearing up by careful collection of specimens. There are inland records (of either or both species?; on passage or wintering?) from Chitral, N. Baluchistan, Delhi, Cachar, Manipur, Madhya Pradesh, Orissa.

Extralimital. 'Breeds from N. Scandinavia eastward to the Murman coast and south to the Gulf of Bothnia, Gulf of Finland, Lake Ladoga and Lake Onega. Winters from the eastern Mediterranean, Red Sea and the Persian Gulf, south to Sierra Leone and the E. African lake region' (Peters). [India.]

GENERAL HABITS. Gregarious. Chiefly a scavenger in seaports, fishing centres and coastal villages, competing with kites and other gulls for scraps and garbage floating on the water, scooping them off the surface in flight or alighting on the water beside them. Often also wades into the surf at the tide's edge to seize a crab or pick up miscellaneous jetam. Occasionally piratical like skuas.

GULLS, TERNS

29

FOOD. Dead fish and offal, scraps and garbage, crabs, marine molluscs and worms, etc. On its breeding grounds highly destructive to eggs and chicks of the smaller gulls and terns and other colonial-nesting sea birds.

VOICE and CALLS. Very similar to the raucous *kee-ow, kee-ow* of the Herring Gull, but deeper and louder. Rather rarely heard in its winter quarters.

BREEDING. Extralimital. For a very good account see Paludan, Knud, 1951, 'Contributions to the breeding biology of *Larus argentatus* and *L. fuscus*'. Copenhagen (Ejnar Munksgaard).

MUSEUM DIAGNOSIS. See Key. For description of plumage see Baker, loc. cit.; Witherby, 1941, 5: 97.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂♂	420-450	50-55	59-66	145-160 mm.
♀♀	405-420	46-49	—	—

2 ♀♀	423-433	58-59	61	158-165 mm.
	(Gujarat coast)			(SA)

COLOURS OF BARE PARTS. 'Iris white to pale straw. Bill yellow with a bright red patch (at the angle) near the tip of the lower mandible; gape and eyelids orange to orange-vermilion. Legs and feet pale yellow to orange-yellow' (Baker).

452a. **Great Blackbacked Gull.** *Larus marinus* Linnaeus
See Appendix

453. **Great Blackheaded Gull.** *Larus ichthyæstus* Pallas

Larus Ichthyæstus Pallas, 1773, Reise Russ. Reichs 2: 713 (Caspian Sea)
Baker, FBI No. 2060, Vol. 6: 101
Plate 45, fig. 6

LOCAL NAMES. For all gulls *Dhokra* (Hindi); *Kheir* (Mirshikars, Bihar).

SIZE. Domestic duck +; c. 66-72 cm. (26-28 in.).

FIELD CHARACTERS. Our largest gull, readily recognized by enormous size and usually solitary habit.

Adult (summer). Head and neck black with two small but prominent crescentic white patches one above one below eye. Mantle pearl grey with a slaty tinge; rest of plumage pure white. Primaries mainly white, the outer ones with subterminal black bands and white tips, the inner ones and secondaries grey with broad white tips. Stout yellow bill with bright red patch at angle. Sexes alike.

In winter head white, more or less mixed and streaked with brownish black. The black head is assumed about February.

Young (immature). Mottled pale brown with almost white head. Wing quills largely brown. Tail with broad terminal blackish band.

STATUS, DISTRIBUTION and HABITAT. Winter visitor to the coasts of India and both Pakistans; occasionally (irregularly) to Ceylon in the Jaffna

GULLS, TERNS

31

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂♂	475-510	60-69	75-84	170-190 mm.
♀♀	435-480	49-61	—	— mm.
				(Witherby)

COLOURS OF BARE PARTS. Adult. Iris hazel brown; fine circumorbital ring coral-red. Bill, basal two-thirds bright yellow followed by a bright reddish orange patch and then by a subterminal blackish-brown band; tips paler yellow; gape and mouth bright orange. Legs and feet bright yellow; claws horny brown. Immature. Circumorbital ring blackish brown. Bill, basal two-thirds greenish yellow or sulphur-yellow, tip reddish orange. Legs and feet greenish yellow or sulphur-yellow. Rest as in adult (SA).

454. **Brownheaded Gull.** *Larus brunnicephalus* Jerdon

Larus brunnicephalus Jerdon, 1840, Madras Jour. Lit. & Sci. 12: 225
(West coast of Indian peninsula)
Baker, FBI No. 2062, Vol. 6: 103
Plate 45, fig. 13

LOCAL NAMES. For all gulls: *Dhokra* (Hindi); *Kādālpāta* (Malayalam); *Kādil kākāi* (Tamil); *Muhudu kaputā* (Sinhala).

SIZE. Jungle Crow ±; length c. 46 cm. (18 in.).

FIELD CHARACTERS. A medium-sized gull, grey above white below with a dark coffee-brown head (the 'hood') in summer. Distinguished from the similar looking Blackheaded Gull (455), with which often seen together,

x.c. 3

by somewhat bigger size and presence of a large white patch, or 'mirror', near the tips of the black primaries.

In winter head greyish white with a vertical black crescent mark behind the ear. Sexes alike. Distinguished from very similar Blackheaded Gull in winter plumage by the prominent wing mirror. Brown head assumed by end March, before emigration.

Young (immature). Brownish mottled with pale grey above. Tail white with a broad blackish subterminal band. Various intermediate phases occur, between this and adult plumage, but wing mirror usually distinguishes it from the confusingly similar Blackheaded Gull.

STATUS, DISTRIBUTION and HABITAT. Breeds in Ladakh. Common winter visitor (August/September to March/April) to the sea coasts throughout both Pakistans, India, and Ceylon. Nepal (vagrant?). Not recorded from the Andaman, Nicobar, Maldivé or Laccadive islands, therefore apparently

CHARADRIIFORMES

30

Peninsula and Northern Province. Not recorded from the Andaman or Maldivé Islands. Occasional inland on large rivers and lakes as winter visitor or passage migrant: recorded thus in northern Baluchistan (Saranan), Sind (Manchar Lake), Punjab Salt Range (Khabakki Lake), Rajasthan (Bharatpur), Delhi (Jumna R.), Nepal (terai), Bihar (Darbhanga dist.), Uttar Pradesh (Corbett Park), Upper Assam (Ranganadi).

Larus ichthyæstus

Breeding range

Extralimital. Breeds in S. Russia from the Crimea, Sea of Azov and the Sarpa Steppes eastward (including Caspian and Aral Seas) to NW. Mongolia and the Irtysh. Winters south to the eastern Mediterranean, Red Sea, Persian Gulf, and the coasts of India and Burma (Peters). Breeding on Tibetan lakes conjectural but highly probable (Ludlow, *Ibis* 1950: 42).

GENERAL HABITS. Usually solitary; occasionally small loose flocks. Once a gathering of 50 + in association with Caspian Terns (Vembanad backwaters, Kerala). Often follows fishing-boats returning to port with the catch for sprats thrown overboard, but seldom enters harbours to scavenge among the shipping like its congeners. Hume noted its predilection for swimming about at sea rather than sitting on the shore as other gulls do when resting, but this is largely because of its far ranging habits in search of food and depends on how far from land the bird is at the time.

FOOD. Chiefly fish and crustaceans. Bills and gullets of specimens taken in Kerala were crammed exclusively with sword-fishes (*Hemirhamphus xanthopterus* C.V.) 19-20 cm. long. Like other large gulls also indulges in piracy.

VOICE and CALLS. A loud raucous *kraa-a*, rather like the Raven's. Seldom heard in its winter quarters.

BREEDING. Extralimital.

MUSEUM DIAGNOSIS. For description of plumage see Baker, loc. cit.; Witherby, 1941, 5: 78-9.

CHARADRIIFORMES

32

does not venture far offshore. Also found in varying numbers inland at most large rivers and lakes, chiefly on passage. Abundant on Sambhar Lake

Larus brunnicephalus

Breeding range Winter

(Rajasthan) throughout winter; in smaller numbers also around the 'Salt Lakes' near Calcutta. On a moderate-sized jheel in Manipur 'a flock of at least ten thousand individuals in March' (Hume, 1888, SF 11: 349). Affects coastal lagoons and backwaters, tidal creeks and estuaries, and the neighbourhood of fishing villages and harbours.

Extralimital. 'Breeds on the inland lakes of the high plateaus of central Asia from Chinese Turkestan to S. Mongolia and south to Ladakh and the eastern Himalayas [?]. Winters on the coasts of southern Asia from the Gulf of Aden to Tenasserim and in the Gulf of Siam' (Peters).

GENERAL HABITS. Gregarious—not different from other gulls. Commonly associates with Pariah and Brahminy kites and other gulls, particularly the Blackheaded (455), in harbours to scavenge kitchen refuse and garbage thrown overboard from ships at anchor. Escorts outgoing and incoming ships and fishing-boats, gliding and circling effortlessly around them for long periods, now ahead now astern, swooping from time to time to pick discarded scraps and offal from the water. Sometimes settles momentarily

GULLS, TERNS

33

In the wake to gobble down a morsel before catching up with the ship again by seemingly leisurely wing-beats, occasionally alighting on the rigging.

MIGRATION. A flock on high-elevation lake in Nepal, c. 5000 m., March 1978?, apparently on aberrant spring passage (Fleming)—CBCN, March 1978: 13.

FOOD. Fish, prawns, and offal. On occasion—in inland localities—insects, grubs, slugs, and earthworms, and shoots of various crops. Has been observed hawking winged termites, and eating floating human ordure from municipal sewage outflows.

VOICE AND CALLS. One call commonly heard, a loud raucous *kreek* very like the Jungle Crow's or Raven's. Much more noisy on its breeding ground than in winter quarters.

BREEDING. On the high plateau lakes in Ladakh at c. 3000-4500 m.—Tsokar, Tso Moriri, possibly Pangong and others. *Season* mainly June-July. *Nest* a mound of grass etc. raised above water level on boggy waterlogged ground on the edge of a lake or on semi-floating spongy grass hummocks or islets. *Nests* colonial, from almost touching to a few metres from one another, as the situation dictates. *Eggs*, normally 3 frequently 2, variable bluish-, greenish- or creamy white, or buff, boldly blotched and spotted with blackish- or reddish brown, with a few hieroglyphic scrawls. Average size of 100 eggs 61.3 × 42.6 mm. (Baker). Both sexes share incubation. Period undetermined.

MUSEUM DIAGNOSIS. For description of plumage see Baker, loc. cit.

		(from skull)		
3 ♂♂	345-360	48-56	50-51.5	130-142.5 mm.
1 ♀	344	54.5	52	134 mm.
				(HW, SA)

COLOURS OF BARE PARTS. Adult. Iris red-brown or yellow-brown (biscuit colour); eyelids deep blood-red. Bill and mouth orange-red to deep blood-red. Legs and feet deep blood-red. Immature. Iris 'almost white' (Baker). Legs and bill more yellow or orange-red, the latter tipped with dusky.

455. Blackheaded Gull. *Larus ridibundus ridibundus* Linnaeus

Larus ridibundus Linnaeus, 1766, Syst. Nat., ed. 12, 1: 225 (European seas = England)

Baker, FBI No. 2061, Vol. 6: 102

Plate 45, fig. 11

LOCAL NAMES. For all gulls: *Dhokra* (Hindi).

SIZE. House Crow ±; length c. 43 cm. (17 in.).

FIELD CHARACTERS. A grey and white medium-sized gull with blackish brown head (the 'hood') in summer. Very similar to Brownheaded Gull, q.v.; distinguished from it by somewhat smaller size and, in flight, in the leading edge of the wing being pure white with no white 'mirror' near tip of primaries.

In winter likewise without black head; then distinguishable from Brownheaded Gull chiefly by wing pattern. Sexes alike. The dark coffee-coloured ('black') head is largely assumed by end March prior to emigration.

3

GULLS, TERNS

35

MIGRATION. No ringing or other precise data. 'A few pass up [through Chitral] from March to May' (Perreau).

GENERAL HABITS. Gregarious, and a scavenger like 454, frequently associated with it in winter.

FOOD. As in 454.

VOICE AND CALLS. Loud and raucous; also similar to 454. Most commonly heard: a querulous scream *kree-ah* and a loud wailing *ka-yek, ka-yek*.

BREEDING. Extralimital. More or less as in 454.

MUSEUM DIAGNOSIS. For description of plumage see Baker, loc. cit.; for fuller details of plumage phases etc. Witherby, 1941, 5: 70-3.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂♂	293-315	31-36	43-49	110-125 mm.
(one 320)				
♀♀	285-302	29-33	—	— mm.
				(Witherby)

COLOURS OF BARE PARTS. Iris dark brown or crimson-brown. Bill, legs and feet deep bright red.

MISCELLANEOUS. Longevity: one ringed as nestling on 13 June 1910 in Cumberland, U.K. found dead in the home colony on 26 May 1930, therefore 20 years old (*British Birds* 24: 55, 1930).

456. Slenderbilled Gull. *Larus genis* Brème

Larus Genis Brème, 1839, Rev. Zool.: 321 (Sardinia)

Baker, FBI No. 2064, Vol. 6: 106

Plate 45, fig. 12

LOCAL NAMES. For all gulls: *Dhokra* (Hindi); *Kothar* (Makran).

SIZE. House Crow ±; length c. 43 cm. (17 in.).

FIELD CHARACTERS. Adult (winter). Confusingly like Blackheaded Gull in size and wing pattern (in flight): head and body, above and below, pure white; mantle pale pearl grey. Differentiated from it, after some experience, both at rest and in flight, by noticeably small head and long neck and longer, bright red bill. Also by absence of brown spot on ear-coverts, and (usually) brighter red legs. Sexes alike.

In summer easily distinguished since head remains glistening white, whilst rest of plumage acquires a delicate rosy flush.

Young (immature) more or less as winter adult, but with some brown on the wing-coverts, and a blackish terminal band on tail. There is a faint pale grey patch on the ear-coverts, and the bill and legs are yellowish red. Adult plumage is acquired in second autumn, *vide* Ticehurst.

For downy chick see Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident and breeding within our limits only in West Pakistan (Makran, Las Bela), numbers there largely augmented in winter by immigrants. Winter visitor to Sind where also 'excessively common along the coast and sometimes up the tidal creeks' (Ticehurst). A specimen taken at Bhavnagar on 5 December (Dharmakumarinhiji). Possibly occurs more commonly on the Kutch-Saurashtra

34

CHARADRIIFORMES

Young (immature). As in 454, also with broad blackish subterminal bar to the white tail.

STATUS, DISTRIBUTION AND HABITAT. Winter visitor (August-September to March-April) to the coasts of both Pakistans and India; more abundant on the Makran and Sind coasts and the western seaboard of the peninsula than on the eastern side. Common up the Hooghly R. from its mouth to Calcutta practically to the exclusion of the Brownheaded Gull (H. G. Alexander); regular but in small numbers (Biswas). Not recorded in Andaman or Nicobar Is. Vagrant to the Maldives; possibly the same in the Laccadives.

Larus ridibundus

■ Breeding range

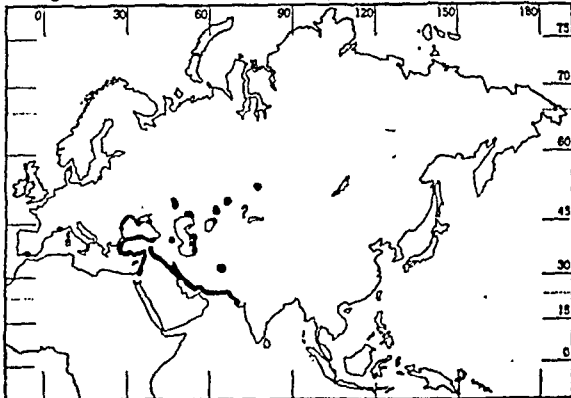

A single sight record from Nilaveli, Sri Lanka (CBCN). Occurs inland in varying abundance and irregularly—perhaps largely on passage—on rivers and jheels. Recorded in Sind (Manchar Lake), Kashmir ('winter visitor'), Chitral (Drosh), N. Baluchistan (Quetta Valley), Delhi (Jumna R.), U.P. (Gorakhpur, Ghazipur), M.P. (Mhow), Punjab (Sutlej R. and lakes in Salt Range), Rajasthan (Sambhar Lake), Nepal (lowland rivers), Assam (N. Cachar), Bihar (Darbhanga district). Published sight records not free from ambiguity with the similar looking Brownheaded Gull. Affects seacoast, estuaries, shipping harbours, and municipal sewage outflows, etc.

Extralimital. 'Breeds in Europe and Asia from Iceland, the Faeroes, British Isles, S. Scandinavia, Finland, Arkhangelsk, lat. 66°40'N. on the Ob, 64° on the Lena, 68° on the Kolyma, and from Kamchatka, south to Sardinia, mouth of the Danube, Central Russia, Transcaucasia, Tarbagatai, N. Mongolia, and Ussuriland. In winter south to the Azores, Gambia, southern shores of the Mediterranean, Nile Valley, Persian Gulf, India, Indochina, Japan and the Philippines' (Peters).

36

CHARADRIIFORMES

coasts than this only positive record indicates, but overlooked among Black-headed Gulls. Since then, in recent years, several specimens have also been collected and observed offshore Greater Bombay (Navarro, 1967, JBNHS 65: 218) and the species may actually be a regular winter visitor to this coast. Nepal (Kosi R.) Feb. 1974—S. C. Madge, *in epist.*

Larus genis

■ Breeding range

Extralimital. 'Breeds on the Black and Caspian Seas, Sea of Azov, Persian Gulf, Makran coast and Sind; S. Spain (?). Ranges throughout the Mediterranean, coast of NW. Africa and the Red Sea' (Peters).

GENERAL HABITS. Not a scavenger like the Black- and Brownheaded gulls, therefore absent in shipping harbours and about coastal villages. But 'huge flocks may be met with not far out at sea feeding on fry as they break the surface; the hindmost birds constantly take the place of the foremost, and they move along, as the fish-shoal moves, with constant screaming and squabbling; when satiated they retire to the sands along the tide's edge, forming a pinkish white line' (Ticehurst).

FOOD. Mainly fish.

VOICE AND CALLS. Not specifically recorded.

BREEDING. Breeds in large mixed colonies with Caspian and Gullbilled terns on the island in Sirunda jheel at Sonmiani (Las Bela, W. Pakistan). Also at other suitable places in Makran. *Season*, May-June. *Nest*, a compacted pad of grass and water-weeds, on the ground. *Eggs*, 2 or 3, variable in coloration and markings. Normally creamy or buffy white, blotched and spotted with blackish brown, with secondary blotches of shades of grey—the markings denser at the broad end. Average size of 200 eggs 55.75 × 38.65 mm. (Baker). Share of the sexes in the domestic chores, incubation period, and other details unrecorded in our area.

GULLS, TERNS

37

MUSEUM DIAGNOSIS. See Key; for description of plumage Baker, loc. cit.
Chick (in down). 'Head, sides of head, upperparts, wings and thighs evenly mottled with about equal areas of black and white alternating; underparts more white but black spots across lower throat and on sides of breast and flanks' (Ticehurst).

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	280-316	38-46	47-55	119-144 mm. (Baker)

COLOURS OF BARE PARTS. Somewhat variable individually. Adult. Iris pale yellow; eyelids bright red. Bill deep crimson red. Legs and feet bright dark red.

457. Little Gull. *Larus minutus* Pallas

Larus minutus Pallas, 1776, Reise Russ. Reichs 3: 702
 (Rivers of Siberia and in Russia = Berezovo, Tobolsk, Siberia)
 Not in Baker, FBI
 Plate 45, fig. 10

SIZE. Pigeon —; length c. 25-30 cm. (10-12 in.).

FIELD CHARACTERS. A diminutive gull distinguished by its small size, absence of black in primaries, blackish underside of wings, and noticeably tern-like flight and movements, flicking food off water surface in its stride etc.

Adult (winter). Above, forehead, lores, and a line over eyes white; crown and nape leaden grey. Upperparts blue-grey; upper tail-coverts and tail white. Primaries blue-grey with white tips, broadly blackish on inner webs. Below, underparts and axillaries white; underwing blackish. Sexes alike.

In summer very like a miniature Blackheaded Gull when at rest, but entire head and upper neck (not only the hood) pure black. Rarely a pink tinge on breast.

STATUS, DISTRIBUTION AND HABITAT. Accidental vagrant. A specimen collected in Ladakh by Walter Koelz.¹ A possible sight record in Bombay Harbour (Magrath, 1910, JBNHS 20: 224) and others in Rann of Kutch (SA, 1974, JBNHS 71: 609).

Extralimital. Breeds in northern Europe and Siberia from Holland and Denmark to the Sea of Okhotsk. Winters on coasts of W. Europe, Mediterranean and Black Seas, Sea of Okhotsk, Japan Sea, etc. (Alexander, 1955).

GENERAL HABITS. The Bombay sight record attributed to this species by the observer was noted as 'a very small gull flying about together with a number of Blackheads'.

FOOD, VOICE AND CALLS. Not recorded in our area; presumably more or less as of 455.

MUSEUM DIAGNOSIS. See Key. For description of plumage and its various phases (also bionomics) see Witherby, 1941, 5: 60-4.

¹No. FMNH 229168, ♀ juv., 21 Sept. 1936, Piting, Ladakh, Field Museum Nat. Hist. Chicago.

GULLS, TERNS

39

458. Indian Whiskered Tern. *Chlidonias hybridus indicus* (Stephens)

Virelva Indica Stephens, 1826, in Shaw's Gen. Zool. 13 (1): 169 (Cawnpore, India)
Hydrochelidon leucoparia leggii Mathews, 1912, Bds. Austr. 2: 320 (Ceylon)
 Baker, FBI No. 2067, Vol. 6: 111
 Plate 46, fig. 3
 Distribution map, p. 61

LOCAL NAMES. For all terns: *Tehāri*, *Gāngā chel*, *Madh louska*, *Koorāri* (Hindi); *Krind*, *Kru* (Kashmir); *Muhudu līhiniyā* (Sinhala); *Kādāl kūrūri* (Tamil, Ceylon); *Rāmadāru*, *Samūdrapu kākī* (Telugu); *Kīri* (Gond); *Kāḍikkāḍka* (Malayalam).

SIZE. Pigeon —; slimmer and longer winged. Length c. 25 cm. (10 in.).

FIELD CHARACTERS. A slender, graceful silvery grey and white bird with long narrow pointed wings and slightly forked (almost square) grey tail,

Winter, × c. 1

usually seen in flight over water. Crown flecked with blackish in winter. Very short red legs and red bill, the latter looking blackish in winter. When at rest on the ground the closed wings project beyond the tail.

In summer the glossy jet black cap down to the eyes, with prominent contrasting snow white cheeks ('whiskers') below it, and the black belly and short-squarish tail, are leading pointers to its identity. Sexes alike.

Young (immature) have the crown and mantle brown, the head darkest and mottled rufous. Underparts and hindneck white.

STATUS, DISTRIBUTION AND HABITAT. Resident and/or breeding visitor in Kashmir and northern India (Gangetic Plain) east to Assam and East Pakistan, spreading out in winter over the entire Union, Nepal (lowlands), and Ceylon. Chiefly passage migrant and/or winter visitor in W. Pakistan (Baluchistan, Sind, Peshawar, Chitral); may breed locally but no definite evidence. Affects inland jheels, marshes and flooded paddyfields; also coastal lagoons, tidal mudflats, and estuaries.

Extralimital. Persian Baluchistan.

GENERAL HABITS. Gregarious. The normal method of feeding in this short-tailed group known as 'Marsh Terns' is for an individual or small flock to fly methodically back and forth on slowly beating wings at a height of 3 to 6 metres or so, bill and eye directed intently below for signs of life. When a gentle wind is blowing the birds work thus slowly and deliberately upwind to the end of their beat scanning the surface carefully, then shoot back downwind to the starting point to repeat the manoeuvre. From time to time one swoops down at a tangent to lightly flick off with the bill something from the surface of land or water, continuing its flight without interruption. Rarely they also plunge from the air in the manner typical of the sea terns. Occasionally the birds hawk flying insects over cultivation,

38

CHARADRIIFORMES

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♂	215-230	21-23	25-29	84-94 mm.
♀ ♀	210-226	21-24	—	— mm. (Witherby)

The Ladakh specimen measures Wing 212, bill (from skull) 31, tarsus 25, tail 83 mm.—Traylor.

COLOURS OF BARE PARTS. Iris dark brown. Bill (ad. summer) red-brown, (winter and juv.) blackish; inside mouth (ad.) orange. Legs and feet (ad. summer) vermillion, (ad. winter and juv.) red-brown to flesh (Witherby).

Terns

Terns differ from gulls in being much more lightly built, with longer narrower wings and different flight. In spite of their webbed feet they rarely settle on water (except *Anous*), resting and roosting on rocks or mudbanks on their ridiculously short legs. They capture their living prey—fishes, insects, crustacea, etc.—by scooping them up from the surface in flight, or by plunging vertically from the air and going under water momentarily.

Unlike gulls they have both mandibles of equal length instead of upper longer than lower. Bill straight, generally slender, with pointed tips; nostrils linear. Tail long and deeply forked in some species, with outer rectrices attenuated and greatly lengthened; only slightly forked (almost square) in others. Wings long; first primary (as.) longest. Legs and feet small.

Genus CHLIDONIAS Rafinesque

Chlidonias Rafinesque, 1822, Kentucky Gazette, n. s. 1(8), Feb. 21: 3, col. 5. Type, by monotypy, *Sterna melanops* Rafinesque = *Sterna surinamensis* Gmelin

Bill short and slightly compressed. Legs and feet small, the webs between the toes deeply emarginate making the feet appear only half webbed; claws long and curved. Wings long, exceeding tail when closed. Tail short and very slightly forked, almost square. All the species are largely dark grey or black on the underparts during the breeding season.

Key to the Species

Adult ♂ ♀. Breeding and Winter

Rump slaty grey.....	<i>C. niger</i>
Rump ashy grey.....	<i>C. hybridus</i>
Rump white.....	<i>C. leucopterus</i>

40

CHARADRIIFORMES

turning and twisting in the chase, or swoop to flick them off ground-crops such as gram (*Cicer*).

FOOD. Insects—dragonflies and their larvae, grasshoppers, water beetles—tadpoles, crabs, fish.

VOICE AND CALLS. A sharp *break, break*, sounding in the distance like the harsh churring notes of the Rufous-backed Shrike (*Lanius schach*); reminiscent also of a louder version of the common Skipper frog's (*Rana cyanophlyctis*), especially when nesting birds are disturbed by an intruder and demonstrate agitatedly overhead.

BREEDING. Recorded localities are: Kashmir Valley (c. 1500 m.), Delhi, U.P. (Lucknow, Fyzabad, Etawah, Gonda), Bihar (Darbhanga, Dhanbad), Assam (N. Cachar), E. Pakistan (Khulna, Sylhet). *Season* overall June to August, varying locally, the first layings (e.g. in Kashmir) being frequently washed away by floods. *Nest*, a small and often flimsy pad of water-lily stems and decaying rushes placed on a floating mat of *singāra* (*Trapa*) plants and other aquatic vegetation, anchored to the substrate and bobbing up and down on the ripples. Built in colonies, sometimes up to a hundred nests or more, a few metres from one another. Pilfering of material from neighbouring nests by swoops from the air an almost universal practice, sometimes resulting in the ravaged nest getting overturned, tipping the contents into the water. *Eggs*, 2 or 3 large, moderate ovals sometimes pointed at the smaller end. They are variable in coloration and markings both as to clutches and individual eggs in the same clutch. A common type is some shade of sea-green, blotched and speckled with brown. Average size of 200 eggs 36.9 × 27.4 mm. (Baker). Both sexes incubate; period undetermined. Male feeds incubating female on fish or other titbit often brought over long distances, sometimes followed by copulation. Downy buff-speckled black chicks when alarmed instantly skeddaddle from nest taking cover among and under the floating water-lily leaves, often lying fully submerged with closed eyes and only the bill showing above.

MUSEUM DIAGNOSIS. Differs from the European and SW. Asian nominate race in having a smaller wing. For description of plumage see Baker, loc. cit. Fresh summer dress is acquired between mid March and end May apparently by a complete moult. 'Young birds of the year at the end of August are already moulting their body feathers, though many of the dark-tipped feathers of the upperparts are yet to be cast. These dark markings vary very much in individuals; in [some] specimens they are so profuse as to make the upperparts appear almost black' (Ticehurst).

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
7 ♂ ♂	221-229	32-37	20-23	76-81 mm.
5 ♀ ♀	213-219	32-36	20-23	77-80 mm. (HW, SA)

For the nominate race Witherby gives Wing ♂ ♂ 232-250, ♀ ♀ 230-242 mm.

COLOURS OF BARE PARTS. Iris dark greyish brown or brown. Bill dark reddish brown to red. Legs and feet dark coral brown to bright or dark red; soles brighter coral; claws black.

MISCELLANEOUS. Large quantities of eggs of this tern (and moorhens etc.) are collected for sale and local consumption by the boatmen in Kashmir. A diminution in the number of birds in certain areas is evident, calling

GULLS, TERNS

41

for early official restriction and regulation of the practice of commercial egg-gathering.

459. Whitewinged Black Tern. *Chlidonias leucopterus* (Temminck)

Sterna leucoptera Temminck, 1815, Man. d'Orn.: 483
(Coasts of the Mediterranean)
Baker, FBI No. 2070, Vol. 6: 114
Plate 46, fig. 2 and Distribution map, p.61

LOCAL NAMES. As under 458.

SIZE. Pigeon —; slimmer. Length c. 23 cm. (9½ in.).

FIELD CHARACTERS. A short-tailed marsh tern, very similar to Whiskered in winter. Doubtfully distinguishable from it except perhaps by slightly smaller size and dull grey (v. silvery grey) mantle.

In partial summer dress, gradually assumed from about mid March, identity unmistakable in flight by the sharp contrasts of dark and white in the plumage. Forehead white, hind head mottled blackish. Underparts dark sooty grey. Under wing-coverts black or blackish contrasting with grey primaries. Tail pure white, nearly square.

In full summer plumage entire head and body velvety black except lower back which is blackish grey. Wing-quills largely silvery grey; tail pure white. Upper wing-coverts, seen as a broad white band in flight, contrasting strongly with black body and underwing lining. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Rare winter visitor to Assam (Cachar), East Pakistan (Sylhet), West Bengal (Calcutta), and Ceylon. Once taken in Madhya Pradesh (Raipur, D'Abreu, 1935, JBNHS 38: 112). Only thrice recorded on the western side of India: once in Bombay (26.iii.1950, Humayun Abdulali) and twice in Saurashtra (Jasdan, June 1949 and 12.v.1955, Y. S. Shivraj Kumar) — JBNHS 49: 310; 53: 130. Pakistan (Karachi dist.) May 1977 (T. J. Roberts, JBNHS 75: 216). A specimen has been taken and a flock sighted in the Andaman Is. (Hume, 1879, SF 8: 495) and more recently also in the Maldives where it is 'probably an infrequent winter visitor' (Phillips, 1963, JBNHS 60: 576). Possibly less vagrant than appears, as liable to be overlooked among the more numerous Whiskered terns with which it keeps in winter, and is impossible to distinguish from satisfactorily before it starts moulting into its distinctive summer dress. However, upper side of tail pure white in this species, grey in Whiskered.

EXTRALIMITAL. 'Breeds in SE. Europe and C. Asia from Hungary and Galicia, C. Russia, Siberia (N. to lat. 55°), Transbaikalia and Amurland, south to Turkestan and N. Mongolia. Winters in tropical and southern Africa to the Orange R. Colony and Damaraland; Persian Gulf, India, Ceylon, Burma, S. China, and the Malay Archipelago to Australia' (Peters).

GENERAL HABITS, FOOD, VOICE AND CALLS. As of Whiskered Tern (458), q.v.

BREEDING. Extralimital. More or less as in 458.

MUSEUM DIAGNOSIS. 'In winter and juvenile absence of dark brown patches on sides of breast, combined with pale rump and short bill distinguish it from other marsh terns' (Witherby). For description of plumage see Baker, loc. cit.; for plumage phases and other details Witherby, 1941, 5: 9-11.

GULLS, TERNS

43

FIELD CHARACTERS. A common pale pearl-grey and white tern, larger than the Whiskered, with deeper-forked white tail and stout black gull-like bill.

In winter, head white streaked with black and with a blackish patch round eye and above ear-coverts; in summer a jet-black cap down to eyes, covering forehead, crown, and nape. Sexes alike.

Young (immature). Crown grey or greyish white. Upperparts, especially scapulars, inner wing-coverts and inner secondaries pale brown with buffish edges. Primaries grey-brown, darker than in adult.

For downy chick see Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Breeding locally in West Pakistan and NW. India (Las Bela and Punjab; doubtless also elsewhere). In winter widespread and locally common, numbers largely augmented by extra limital immigrants. Practically the entire Indian Union (see also 461) from

Gelochelidon nilotica

■ Breeding range 1 *G. n. nilotica* (460). 2 *G. n. effusa* (?) (461).

Makran coast and Sind eastward across Rajasthan and the Gangetic Plain to Bihar, south through the Peninsula to Kanyakumari, and Ceylon. Presumptive breeding in Ceylon not yet confirmed. Specimens obtained in the Maldives (December) but status there uncertain. Affects coastal mudflats, backwaters, tidal creeks, salt pans, etc., and large inland jheels and rivers.

EXTRALIMITAL. 'Breeds locally in Europe and the western three-quarters of Asia from Denmark, Baltic Sea, Middle Urals, Zaisan-nor and S. Mongolia (perhaps north to Transbaikalia) south to the Iberian Peninsula, NW. Africa, Asia Minor, Persia, India (east to the Ganges) and Ceylon [?]. Winters in northern and eastern tropical Africa, Persian Gulf and India; occasionally to the Sunda Is.' (Peters).

IMMIGRATION. No ringing data. Fair numbers on passage through Chitral 'during end April and May' (Perrau, 1910, JBNHS 19: 921) and through

42

CHARADRIIFORMES

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail central outer	Depth of fork
♂♂	200-218	23-24	19-22	58-67	67-75
♀♀	192-210	—	—	—	5-11 mm.

COLOURS OF BARE PARTS. Iris dark brown. Bill (ad.) black tinged crimson. (juv. and 1st winter) black-brown tinged orange at gape. Legs and feet (ad.) bright vermilion. (juv. and 1st winter) red to red-brown (Witherby).

459a. Black Tern. *Chlidonias niger niger* (Linnaeus)

Sterna nigra Linnaeus, 1758, Syst. Nat., ed. 10: 137 (near Upsala, Sweden)
Not in Baker FBI
Plate 46, fig. 1

SIZE. Same as 459; length c. 23 cm. (9½ in.).

FIELD CHARACTERS. In winter differs from Whiskered Tern by dull grey v. silvery grey mantle; from Whitewinged Black chiefly by black of hind head continuing as a dark patch on either side of neck in front of base of wings.

Summer plumage unmistakable: dark slate-grey above, black below without the white wing-shoulder or white tail of 459.

STATUS. Sight recorded near Delhi, 11 October 1949, with adequate corroborative evidence by an experienced observer familiar with the species in Europe. (H. G. Alexander, JBNHS 49: 120-21). Confirmatory specimen desirable.

Genus GELOCHELIDON Brehm

Gelochelidon C. L. Brehm, 1830, Isis von Oken, 23, col. 994

Type, by monotypy, *Gelochelidon meridionalis* Brehm = *Sterna nilotica* Gmelin

Differs from *Sterna*, q.v., in its stouter bill. Feet fully webbed as in *Sterna*; tarsus longer than middle toe and claw. Tail comparatively shorter than in *Sterna* with the outer feathers less prolonged.

GELOCHELIDON NILOTICA (Gmelin)

Key to the Subspecies

Larger, wing 300-333 mm.; culmen 35-41 mm.	<i>G. n. nilotica</i>
Smaller, wing 272-292 mm.; culmen 32-35 mm.	<i>G. n. effusa</i>

460. Gullbilled Tern. *Gelochelidon nilotica nilotica* (Gmelin)

Sterna nilotica Gmelin, 1789, Syst. Nat. 1(2): 606 (Egypt)
Baker, FBI No. 2072, Vol. 6: 117
Plate 46, fig. 15

LOCAL NAMES. As under 458. *Kirru*, *Deeri arena* (Maldives).

SIZE. House Crow —; length c. 38 cm. (15 in.).

44

CHARADRIIFORMES

Kohat 'from beginning of April till May — last seen 5th May' (Whitehead, 1911, ibid. 20: 975).

GENERAL HABITS. Gregarious, but frequently seen singly or in twos and threes or small scattered flocks, and in association with other river and marsh terns. Seldom met far offshore along the coast. Flies low over sand- and mudflats, swooping down at a tangent from time to time to pick up some titbit in its bill as it skims close to the surface. Sometimes hawks flying insects over cultivation and stubbles in company with Whiskered Terns, and dips in low flight to scoop up a caterpillar or grasshopper from off ground-crops like gram or groundnut. On the coast flocks together to rest with gulls and other terns at the edge of the tide waiting for the ebb to expose the feeding flats.

FOOD. Largely sand crabs (*Oxyrops*) on the sea coast. Also prawns and other crustacea, frogs, small fish, and insects. Floating ordure from municipal sewage outflow recorded in Cochin Harbour.

VOICE AND CALLS. Not intelligibly described in India. 'Scolding cries of *zit, kuzikterick* or a high-pitched *hik...hikihikihikihik* while flying around one' (G. M. Henry, Ceylon).

BREEDING. Recorded on sandbanks in the Punjab rivers — Chenab, Beas, Sutlej — and on an island in Sirunda jheel, Las Bela. *Season* end April to end June, varying with local conditions. *Nest* a slight depression in the sand, according to Waite (1917, JBNHS 25: 300) characteristically with some small pieces of sticks or other debris which identifies it at once among the bare unlined depressions of River Terns and Skimmers nesting with it in mixed colonies. *Eggs*, 2 or 3, broad to moderately long ovals of variable coloration from pale yellowish- or greenish stone to buffy brown or brown, boldly blotched with purple, red, or blackish brown and with secondary markings of grey and lilac. Average size of 100 Indian eggs 47.9 x 34.2 mm. (Baker). Share of the sexes in incubation, period, and other details of breeding biology not recorded.

MUSEUM DIAGNOSIS. Differs from the eastern race *effusa* (461) in having a longer wing and somewhat longer bill. For description of plumage see Baker, loc. cit.; for details of plumage phases etc. (and bionomics), Witherby, 1941, 5: 12-14.

CHICK (in down). 'Upperparts dirty grey-buff with black spots on crown, behind eyes and the dorsum where they tend to form stripes; carpus white, throat dusky to blackish, rest of underparts nearly white' (Ticehurst).

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail central outer	Depth of fork
♂♂	315-332	34-41	33-37	89-93 120-138	30-48 mm.
♀♀	320-330	—	—	—	—

COLOURS OF BARE PARTS. Iris black-brown. Bill black. Legs and feet (ad.) black, (juv. and 1st winter) dark red-brown (Witherby).

461. Javan Gullbilled Tern. *Gelochelidon nilotica effusa* (Horsfield)

Sterna effusa Horsfield, 1821, Trans. Linn. Soc. London 13(1): 199 (Java)

LOCAL NAMES. As under 458.

GULLS, TERNS

45

SIZE. As of 460; length c. 38 cm. (15 in.).

FIELD CHARACTERS. Same as the nominate race (460) q.v. Slightly smaller but otherwise indistinguishable. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Breeding locally (race presumed) in West Bengal and East Pakistan (Khulna Sunderbans). Found in winter east of Bihar — W. Bengal, Orissa, and through Assam and E. Pakistan. A specimen taken in the Andaman Is. in November; status there uncertain. In non-breeding season the ranges of the races overlap, making subspecific identification of individual specimens impossible. Extralimital range not yet properly worked out. Inhabits islands of the Malay Archipelago.

GENERAL HABITS, FOOD, VOICE AND CALLS. Not different from 460.

BREEDING. A very large colony with eggs — many quite fresh — discovered on an island in the Khulna Sunderbans on 22 April 1922 (Stanford, 1937, JBNHS 39: 867). Skins of breeding birds needed to confirm the subspecies which is only presumed.

MUSEUM DIAGNOSIS. Differs from the western (nominate) race only in having a smaller wing (272-292 mm. *vide* Baker), and somewhat shorter bill (32-35 mm. from feathers).

COLOURS OF BARE PARTS. As in 460.

Genus *Hydroprogne* Kaup

Hydroprogne Kaup, 1829, Skizz. Entw.-Gesch. Eur. Thierw.: 91. Type, by subsequent designation, *Sterna caspia* Pallas = *Sterna tischgravi* Lepechin

Distinguished from *Gelochelidon* by greater size, comparatively short tarsi, shorter tail, and very large stout red bill. Only the nominate race occurs in our area.

462. Caspian Tern. *Hydroprogne caspia caspia* (Pallas)

Sterna caspia Pallas, 1770, Novi Comm. Acad. Sci. Petropol. 14(1): 582, pl. 22

(Caspian Sea)

Baker, FBI No. 2071, Vol. 6: 115

Plate 46, fig. 10

LOCAL NAMES. As for other terns (see under 458). *Kākra* (Sind); *Māruwudu* *lithimā* (Sinhala); *Periya kādai kūrāi* (Tamil, Ceylon).

SIZE. Jungle Crow +; length c. 51 cm. (20 in.).

FIELD CHARACTERS. The largest of our terns; recognizable by its size and very large, stout coral-red bill and black legs and feet.

Adult (winter): Above, pearl-grey with white head and neck (all round), streaked on the crown with black; below, pure white.

In summer, forehead and crown to below eyes glossy jet black. Sexes alike.

Summer, x c. 1

GULLS, TERNS

47

and plunging at the quarry, often submerging completely. Sometimes alights on water like a gull, but normally rests on the ground, on sandspits, etc.

FOOD. Mainly fish, prawns and swimming crabs. Seldom any terrestrial items or flotsam refuse.

VOICE AND CALLS. A loud raucous *krake-krake* (whence its Sindhi name). G. M. Henry describes a loud squawk *kuwuw, kuwuw*, probably an alarm or scolding note, and 'a harsh cry *kruuxiair* repeated several times by a bird flying along a lagoon shore'.

BREEDING. Recorded breeding localities within our limits: Sirunda jheel at Sonmiani, Las Bela, and Astola (or Astalu) Island off the Makran coast (W. Pakistan); sandbanks off the island of Mannar (Ceylon). Breeds in colonies mixed with Gullbilled and other terns. Season, May and June. Nest, a shallow scrape in the sand, c. half a metre or so away from its neighbours. Eggs, 2 or 3, broad to long ovals, varying in ground colour from pale yellowish or greyish stone to dull dark buff, occasionally with a pinkish tinge. Blotched with deep brown or blackish brown, with secondary blotches of grey. Average size of 30 Indian-taken eggs 64.8 x 46.0 mm. (Baker). Both sexes incubate. Period undetermined; elsewhere recorded as 20-22 days.

MUSEUM DIAGNOSIS. For description of plumage see Baker, loc. cit.; for details of plumage phases and structure etc. (also bionomics) Witherby, 1941, 5: 15-18.

CHICK (in down). 'Like *nilotica* (460, q.v.), but much fewer spots on crown and dorsum, and none behind the eyes' (Ticehurst).

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail central outer	Depth of fork
♂♂	398-425	64-72	45-47	98-110 135-150	30-45 mm.
♀♀	400-425	—	—	—	—

COLOURS OF BARE PARTS. Iris dark brown. Bill (ad.) rich coral-red, (juv.) paler, tipped dusky. Legs and feet black (Witherby).

Genus *STERNA* Linnaeus

Sterna Linnaeus, 1758, Syst. Nat., ed. 10, 1: 137. Type, by tautonymy, *Sterna hirundo* Linnaeus (*Sterna prebinomial* specific name in synonymy)

Thalassea Boie, 1822, Isis von Oken, Bd. 1, col. 563. Type, by subsequent designation, 'Th. cantianus' = *Sterna cantianus* Gmelin = *Sterna sandvicensis* Latham

Bill rather long, pointed, more or less compressed laterally, straight or slightly curved throughout. Tarsus shorter than middle toe with claw. Feet small; front toes completely webbed; a hind toe present. Wings long and pointed: first primary (as.) longest. Tail deeply forked, the outer tail-feathers much longer than the rest, narrowing into a 'streamer' towards tip.

Genus world-wide with 12 species and several races normally occurring in our area.

Key to the Species

B Bill shorter (under 49 mm.), slender, straight and more or less laterally compressed.....2	
1 Bill black, tipped yellow..... <i>S. sandvicensis</i>	70

46

CHARADRIIFORMES

Young (immature). Head as in winter adult. Upperparts grey barred with brown, especially on scapulars and innermost secondaries. Tail-feathers and primaries darker than in adult.

For downy chick see Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Breeds locally in W. Pakistan and Ceylon. In winter spreads out sparingly more or less throughout the sub-continent, locally common, its numbers doubtless augmented by extralimital immigrants. Occurs sparingly also in the Maldives Is. (status?). Affects the sea coast, tidal mudflats, estuaries and backwaters (Kerala), and the larger lakes (e.g. Manchar, Chilka) inland.

Extralimital. Breeds very locally in Europe and Asia over a wide range of latitudes, between c. 10°N. (Ceylon) and 60°N. (Finland). Also breeds in Africa and N. America. In the Old World winters south to Africa, India and the Sunda Is.

MIGRATION. A party of 7 birds blown down in a storm at Thull (in the former N.W.F.P.) on 22 May 1898 (Rattray, 1899, JBNHS 12: 347) was evidently on passage. In Baluchistan 'visits such waters as Khushdil Khan and Saranan lakes on passage. Meinertzhagen noted them there from April 30 to May 17' (Ticehurst, 1927, *ibid.* 32: 86). An example ringed in the Dzhambul Region of Kazakhstan (c. 43°30'N., 70°40'E.) on 1.vii.1961 has been recovered on the Ganges R. in West Bengal (c. 25°20'N., 87°35'E.) on 3.xi.1964 (*ibid.* 61: 693).

GENERAL HABITS. In non-breeding season less gregarious than most other terns, usually seen singly or in twos and threes either by themselves or in

Hydroprogne caspia

■ Breeding range

association with other species. Hunts in the manner characteristic of the sea terns — hovering over a likely spot of water with bill pointing downwards

463. Indian River Tern. *Sterna curantia* J. E. Gray

Sterna curantia J. E. Gray, 1831, in Hardwicke's Ill. Ind. Zool. 1(5): pl. 69, f.2 (India)

Baker, FBI No. 2080, Vol. 6: 125

Plate 46, fig. 9

LOCAL NAMES. In general as under 458. *Kūnāi* (Sind).

SIZE. House Crow ±; slenderer. Length c. 38-46 cm. (15-18 in.).

FIELD CHARACTERS. A slender, graceful fluviatile bird, pale grey above white below, with long narrow pointed wings, deeply forked 'swallow' tail, very short red legs, and pointed deep yellow bill.

Summer, x c. 1

In winter, crown and nape flecked and streaked with black. In summer (breeding plumage) entire forehead, crown, and nape down to below eyes

glossy jet black. A horizontal crescentic white patch below eyes. Sexes alike. Young (immature). Upperparts, including wing and tail-feathers edged with buffy white and subedged terminally with blackish. Forehead and a broad supercilium pure white.

STATUS, DISTRIBUTION and HABITAT. Resident and breeding widely on sandy islets in rivers chiefly in the plains practically throughout the Indian Union (including Kashmir Valley), both Pakistans (including the former N.W.F. Province and Punjab Salt Range) and Nepal (lowlands). Absent in Ceylon. Rare on the seaboard and less common in southern peninsular India. Affects the larger rivers, estuaries, and tanks.

Extralimital. Burma and Malay Peninsula east to the Mekong river.

GENERAL HABITS. Keeps singly or in twos and threes, or small scattered parties flying deliberately up and down placid stretches of rivers or large tanks, scanning the water below for prey. Normally hunts by plunging from a height with wings pulled in, often submerging completely, presently to reappear with a small fish held crosswise in the bill. As it resumes its flight, with a little shrug to shake off the water from its feathers, the victim is jerked into position and swallowed head foremost. When satiated the birds flock to rest — as they also roost at night — on sandbanks, the entire gathering with head to wind. When one bird is shot and drops to the ground, its companions in the air will almost instinctively dive down after him presumably meaning to share in his imaginary spoils. Numbers will soon gather at the spot, flying around in a disorderly rabble overhead to investigate.

FOOD. Chiefly fish; also crustaceans and aquatic insects.

VOICE and CALLS. Not specifically recorded. While swooping at intruder in nest colony, making as if to strike, a loud drawn-out note *ping* 'sounding like the scream of a bullet whistling past' (Lowther).

BREEDING. Colonial. *Season*, March to May. *Nest*, a shallow scrape or depression on the bare sand on sandspits and islets in large rivers, often in company with pratincoles, other tern species and skimmers. *Eggs*, normally 3, rarely 4, broad ovals only slightly smaller at one end than the other. Coloration very variable — from buffy stone to greenish grey, spotted, blotched, and streaked with brown and inky purple. Average size of 200 eggs 42.0 × 31.4 mm. (Baker). Both sexes incubate. Period recorded as 'about 18 to 19 days'. Frequently the first crop of eggs is washed out by untimely floods, necessitating a second or even third laying in quick succession.

MUSEUM DIAGNOSIS. See Key to the Species; for further details of plumage Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail (outer feathers)
♂ ♀	260-280	39-43	c. 20-22	178-228 mm. (Baker)

Depth of fork c. 50-80 mm. (SA).

COLOURS OF BARE PARTS. Iris brown. Bill (summer) bright deep yellow; (winter) less bright yellow with a darker tip. Legs and feet red.

× c. 4
Distal portions of outermost primaries of A. *S. macrura* (466a), B. *S. hirundo* (464), and C. *S. dougallii* (466).
N.B. There is considerable individual variation in the width of the black line on inner web in A and B. The white at tip in C is diagnostic.

MUSEUM DIAGNOSIS. For description of plumages, structure, etc. (also bionomics) see Witherby, 1941, 5: 28-35.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail central outer	Depth of fork
♂ ♀	255-288	33-39	19-21	68-87 135-175	65-95 mm.
♀ ♀	255-280	—	—	65-76 140-160	64-86 mm.

COLOURS OF BARE PARTS. Iris dark brown. Bill (ad. winter) mostly black, sometimes some crimson at base; (ad. summer) scarlet, tip black; (juv.) as winter but black portion browner and base more yellowish. Legs and feet (ad. winter) red to red-brown; (ad. summer) vermillion; (juv.) yellow-orange (Witherby).

465. Tibetan Common Tern. *Sterna hirundo tibetana* Saunders

Sterna tibetana Saunders, 1876, Proc. Zool. Soc. London: 649 (Tibet)

Baker, FBI No. 2084, Vol. 6: 130

LOCAL NAMES. In general as under 458.

SIZE. Same as 464; length c. 36 cm. (14 in.).

FIELD CHARACTERS. As for 464 but darker and slightly browner above, darker below. Difference less pronounced in winter, and the races then indistinguishable. Sight records unreliable.

For downy chick see Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Breeds in Ladakh. Winter visitor to the Indian Union and East Pakistan; fairly common in the Gangetic Plain, less common to scarce in the Peninsula. Irregular visitor to Ceylon, sometimes in considerable numbers. Overall status given by Baker as 'a very common visitor to the whole of western and central India' is palpably erroneous. Affects the larger rivers and jheels, and tidal creeks and estuaries.

STERNA HIRUNDO Linnaeus

Key to the Subspecies

Purer grey above and below and distinctly paler below in breeding plumage.....	<i>S. h. hirundo</i>
Browner grey above and below and decidedly darker below in breeding plumage.....	<i>S. h. tibetana</i>

464. European Common Tern. *Sterna hirundo hirundo* Linnaeus

Sterna Hirundo Linnaeus, 1758, Syst. Nat., ed. 10, 1: 137 (in Europa = Sweden)

Baker, FBI No. 2083, Vol. 6: 129

Plate 46, fig. 8

LOCAL NAMES. In general as under 458.

SIZE. House Crow —; slimmer. Length c. 36 cm. (14 in.).

FIELD CHARACTERS. A grey-mantled tern with deeply forked white tail of which the longest outer feathers, or streamers (grey and white), do not project beyond the wing-tips when bird at rest.

Adult (winter). Upperparts ashy grey. Forehead white or mottled with white; crown streaked with black. *Below*, chin, throat, wing-lining and under tail-coverts white; breast and abdomen greyish white with a vinous tinge. First primary largely black, and blackish bill with red base are suggestive clues for differentiation from confusingly similar Roseate Tern (466) and Arctic Tern (466a) in winter.

In summer a black-cap covers forehead, lores, and crown to lower edge of eye, and the bill becomes coral-red with black tip. Sexes alike.

Young (immature). Like adult in winter but mantle mottled with greyish brown; a dark band on upper wing-coverts; outer webs of tail-feathers dark grey. Bill brownish.

STATUS, DISTRIBUTION and HABITAT. Status anomalous in Sind and in Baluchistan where the birds definitely belong to the nominate race. Chiefly winter visitor but some non-breeding individuals staying on in Karachi Harbour and probably other suitable inlets throughout the hot weather. Probably a passage migrant in Lower Baluchistan — Makran etc. (Tiechurst). Reported by Meinertzhagen as plentiful (non-breeding) on Khushdil Khan lake near Quetta (N. Baluchistan) in May, and early June. No definite records of the nominate race traceable in India. Affects tidal creeks, estuaries, and large inland waters.

Extralimital. Breeds in N. America, Europe and W. Asia — Norway, Finland, etc., in the valleys of the Ob and Yenisey, Black and Caspian Seas, Iran, Iraq, Tarbagatai, etc. In the Old World winters to west coast of Africa, and Makran coast. (For fuller details see Peters, 2: 332; Vaurie, 2: 494-5.)

MIGRATION. No ringing data.

GENERAL HABITS. Similar to other terns. Hunts mainly by plunging

FOOD. Mainly fish. Also crustaceans, molluscs and insects.

VOICE and CALLS. Not recorded in Indian winter quarters.

BREEDING. Extralimital. More or less as in 463.

Extralimital. 'Breeds on the inland waters of Turkestan, Ladakh and Tibet. Winters in central and eastern India and the Malay states' (Peters).

GENERAL HABITS and FOOD. Similar to 464.

VOICE and CALLS. Not intelligibly described.

BREEDING. Breeds commonly on the high-elevation lakes in Tibet, and evidently also Ladakh — Pangong, Tsokri, Tso Moriri (?) etc. c. 3500 m. — though no recent investigator has actually found eggs there. *Season* in Tibet chiefly June-July. *Nest*, sometimes solitary, usually colonial, amongst a mass of dried weeds and grass — occasionally a mere scrape amongst pebbles on the bare shore of an islet in a lake, or on a small grassy hummock in the middle of a bog. *Eggs*, 2 or 3, varying from pale dull grey-green to yellowish stone-colour, blotched with dark brown, reddish brown or blackish, with secondary blotches of grey or lavender-grey. Average size of 50 eggs 41.9 × 30.5 mm. (Baker). The birds generally betray their nests by their loud cries and agitated behaviour. They are bold in attacking intruders, 'one bird stooped 20 or 30 times like a falcon while its nest was being photographed' (Ludlow).

MUSEUM DIAGNOSIS. See Key.

Chick (in down) indistinguishable from nominate race. *Above*, pale sandy or buff mottled on back with black; crown generally marked with two fairly well-defined lateral black bands and a less well-defined central one. *Below*, throat and foreneck purplish brown, paler on the chin; rest of underparts white.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail (outer feathers)
♂ ♀	245-279	34-38	c. 19-22	145-156 mm. (Baker)

Weight 5 oo? 102-110 gm. — BNHS.

COLOURS OF BARE PARTS. As in the nominate race.

466. Roseate or Rosy Tern. *Sterna dougallii korustus* (Hume)

Sterna korustus Hume, 1874, Stray Feathers 2: 318 (Andaman Islands)

Baker, FBI No. 2086, Vol. 6: 132

Plate 46, fig. 6

LOCAL NAMES. In general as under 458.

SIZE. House Crow —; slimmer. Length c. 38 cm. (15 in.).

FIELD CHARACTERS. A slender grey and white tern with deeply forked tail; practically indistinguishable from 464 and 465 in winter, but longer *pure white* outermost tail-feathers or streamers (v. grey and white) noticeable by those familiar with both species.

Adult (winter). Forehead and forecrown white speckled with black; crown and nape black. Underparts white with a very faint rosy flush. Bill black.

The bright red legs readily distinguish it from Blacknaped Tern — also with rosy tinged underparts — which has black legs.

In summer (breeding) forehead, crown, and nape down to lower edge of eye black. White underparts suffused with rosy. Bill black with red base. Sexes alike.

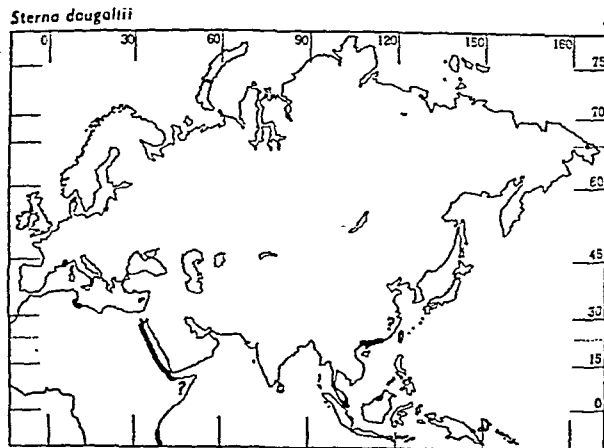

GULLS, TERNS

53

Young (immature). Above, forehead spotted, and crown streaked with brown, black, and white. Upperparts white with double bars of brown rump and upper tail-coverts ashy grey, sometimes mottled with brown; Below, white.

For downy chick see Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Breeds in the Andamans (islets off Port Blair), off the southeastern and west coasts of India (Rameswaram I.,

Breeding areas

Vengurla Rocks), Ceylon (west coast and east coast islets), and reportedly also the Maldives (Fujarde islet). Non-breeding range and movements imperfectly known. Affects sea coast and offshore islets.

Extralimital. *S. d. korustus* breeds also in the islands of the Mergui Archipelago, South Burma; other races as shown on map.

GENERAL HABITS. A sea tern confined to coastal waters and offshore islets.

FOOD, VOICE and CALLS. Nothing recorded as significantly different from other sea terns, e.g. the Crested (478, 479), q.v., with which it freely associates.

BREEDING. Breeds in mixed colonies, sometimes of considerable size, with Blacknaped and Crested terns. Season April-May-June, varying locally and also in different years. Nest, a scrape in the sand sometimes scantily lined with debris and small shells and pebbles, or amidst scraggy grass tufts on rocky islets. Eggs, 1 or 2 — very rarely 3. Similar to those of Tibetan Tern (465) but somewhat smaller. Variable in coloration, most commonly pale yellowish or greyish stone with numerous freckles and some large blotches of dark brown, reddish brown, purple-black or black, and secondary

GULLS, TERNS

55

467. Whitecheeked Tern. *Sterna repressa* Hartert

Sterna repressa Hartert, 1916, Nov. Zool. 23: 298 (Fao, Persian Gulf). New name for *Sterna albigena* of authors, not Reichenbach

Baker, FBI No. 2082, Vol. 6: 128

Plate 46, fig. 7

LOCAL NAMES. In general as under 458.

SIZE. House Crow —; length c. 35 cm. (13½ in.).

FIELD CHARACTERS. Confusingly similar to Tibetan and Arctic terns; difficult to differentiate with certainty unless in the hand. See Key and Museum Diagnosis.

Adult (summer). Above, black upperparts of head, including upper lores, not descending to lower edge of eye (giving a white-cheeked effect). Upperparts including tail-coverts, tail, and wings dark ashy grey. Below, chin white; rest of underparts ashy grey with a lilac tinge. Legs bright red. Sexes alike.

In winter head white, the feathers round the eye, nape, and upper hindneck more or less black or chocolate-brown; lower hindneck and underparts white.

STATUS, DISTRIBUTION and HABITAT. Breeds on Vengurla Rocks off Malvan on the west coast, c. 16°N., 73°30'E. Common on Makran and Sind coasts, March to May, but no evidence of breeding; probably only on passage to its breeding grounds in the Persian Gulf. Records on Tamil Nadu and Maharashtra coasts scanty, possibly due in part to difficulty in field identification of terns. A specimen, Bombay harbour, 12.vi.1973 (Prabhakara Menon, JBNHS 71: 610). Obtained in the Laccadive Is. by Hume; not recorded in Ceylon or the Andaman Is.

Extralimital. 'Southern parts of the Red Sea, coasts of Somaliland and Kenya Colony, Arabian Sea and Persian Gulf to the Malabar coast and the Laccadive Islands' (Peters).

GENERAL HABITS, FOOD, VOICE and CALLS. A maritime tern, sometimes met many miles out from the coast, but avoiding inland waters. Hunts by plunging from the air; other behaviour also typical of the sea terns. Nothing specifically recorded.

BREEDING on the offshore islets south of Ratnagiri on the West Coast (Vengurla Rocks) where added eggs and desiccated remains of the birds have been picked up after the breeding season during which the heavy monsoon seas make landing on the rocks impossible. The birds evidently nest here in mixed colonies together with Large Crested, Roseate, Sooty, and Brownwinged terns (Abdullah, JBNHS 1940, 41: 661; 1942, 43: 448). Season, the SW. monsoon — evidently May and June, perhaps into July. Nest, (description from islets off the Somali coast) a shallow depression on open sand flats or in sand accumulated by wind and wave action in hollows and roughnesses of sheet rock, sometimes lined — deliberately or fortuitously (?) — with bits of twig and grass stems. The nests placed close to one another. Eggs, 2 or 3, occasionally only 1. Coloration variable, from stone or whitish- to olivaceous buff, spotted and streaked with dark reddish brown, with secondary markings of lilac. Average size of 100 eggs 40.8 × 30.4 mm. (Baker).

MUSEUM DIAGNOSIS. For description of plumage see Baker, loc. cit.

54

CHARADRIIFORMES

markings of grey or lavender. Average size of 100 eggs 40.2 × 29.3 mm. (Baker). Incubation by both sexes; period undetermined.

MUSEUM DIAGNOSIS. For description of plumage phases and structure (also bionomics) of the nominate race see Witherby, 1941, 5: 24-7. The race *korustus* differs from it only by slightly darker plumage and slenderer bill.

Chick (in down). Upperparts, chin and throat grey tinged with buff or rich buff, the black bases of the down showing through. Rest of underparts white.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail (outer feathers)
♂ ♀	210-226	31-38	c. 20-22	130-164 mm. (Baker)

COLOURS OF BARE PARTS. Iris dark brown. Bill (winter) black or (breeding) red with terminal third blackish. Legs and feet bright red.

466a. Arctic Tern. *Sterna macrura* Naumann

Sterna macrura Naumann, 1819, Isis: 1847 (Island Nordstrand and coast of West Schleswig)
Not in Baker

SIZE. As of Tibetan Common Tern (465). Length c. 36 cm. (14 in.).

FIELD CHARACTERS. Similar to 464 and 465 'but throat, breast and abdomen French-grey with no vinaceous tint; a white streak on the sides of the head below the black cap (in summer); outermost primaries with inner web narrowly grey next the shaft; secondaries broadly margined with white; outside tail-feathers very long with dark grey outer webs; bill blood red; feet coral red' (Alexander, 1955).

Extralimital. Breeds in the Holarctic Region chiefly between 60° and 75° N. lat. Winters in the Antarctic Ocean south to c. 75° S. lat. performing an annual return migration of over 35,000 km.

STATUS, DISTRIBUTION and HABITAT. The only record for our area is an adult male in full breeding plumage, presumably a lost vagrant, collected on 2 July (1928) in the Suru Valley, Kashmir, c. 4000 m. along with Tibetan terns (Whistler, 1936, *Ibis*: 600).

MUSEUM DIAGNOSIS. For description of plumages and structure see Witherby, 1941, 5: 38-40.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail central outer	Depth of fork
♂ ♂	265-282	30-33	15-17	70-80 170-200	90-138 mm.
♀ ♀	260-275	—	—	66-75 158-185	92-117 mm.

COLOURS OF BARE PARTS. Adult. Iris dark brown. Bill winter blackish, summer blood-red, occasionally with blackish tip. Legs and feet, winter blackish, summer coral-red (Witherby).

468. Eastern Blacknaped Tern. *Sterna sumatrana sumatrana* Raffles

Sterna Sumatrana Raffles, 1822, Trans. Linn. Soc. London 13 (2): 329 (Sumatra)
Baker, FBI No. 2092, Vol. 6: 139

Plate 46, fig. 12

LOCAL NAMES. In general as under 458; *Sterna yena* (Car Nicobar).

SIZE. House Crow —; length c. 35 cm. (13½ in.).

FIELD CHARACTERS. A pale pearly grey and white sea-tern, looking particularly white against the dark grey sea. Distinguished by a black band commencing in front of eye and encircling the sides of head and nape. Rest of head white. Tail deeply forked: central feathers grey, streamers white. Underparts white suffused with delicate rosy pink. Legs and bill black. Sexes alike.

In winter black nuchal band narrower and less prominent.

Young (immature) has the nape dark chocolate-brown, inner wing-coverts dark grey-brown, primaries dark grey.

In first-feather plumage (succeeding the down) crown brownish; feathers of upperparts with wavy brown bars.

STATUS, DISTRIBUTION and HABITAT. Common in the Andaman and Nicobar Islands, between May and October, mostly dispersing over the adjacent seas after breeding. May occur in Khulna Sunderbans of East Pakistan and West Bengal.

Extralimital. Breeds also on other small islets in the tropical Pacific and eastern Indian oceans south to the Sunda Is. and c. 20°S. lat.

GENERAL HABITS, FOOD, VOICE and CALLS. Exclusively maritime. Food chiefly fish caught by plunging.

BREEDING. Breeds on small rocky islets off the east coast of the Andamans (and Nicobars?) — more sheltered during the SW. monsoon. Season, May to July. Nest, a skimpy bed of a few small fragments of coral collected on the rock, or mere dimples in sand. In small scattered colonies each nest separated by several metres from its neighbour. Eggs, 2 or 3, sometimes only 1. Variable in coloration and very similar to eggs of *S. dougalii* — mostly greyish stone with numerous spots of dark or light brown; some much warmer coloured with reddish brown blotches; others yellowish brown or pale green in ground colour instead of grey. Average size of 200 eggs 39.6 × 28.6 mm. (Baker).

GULLS, TERNS

57

MUSEUM DIAGNOSIS. See Key. For fuller description of plumage, Baker loc. cit.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail (outer feathers)
♂ ♀	220-227	31-38	18-19	129-150 mm. (Baker)

Wing 3 ♂♂ (Andamans) 215, 216, 227; 6 ♀ ♀ 208-224 (av. 213) mm. (Abdulali).
COLOURS OF BARE PARTS. Iris brown. Bill black with a small yellowish tip (c. 15 mm.) to both mandibles, not always present. Legs and feet black.

469. **Western Blacknaped Tern.** *Sterna sumatrana matthewsi* Stresemann
Sterna sumatrana matthewsi Stresemann, 1914, Nov. Zool. 21: 60
(Aldabra Islands, type from Ile Piquart)
Not in Baker, FBI

LOCAL NAMES. Kirru dooni (general for terns — Maldivian).

SIZE. House Crow — ; length c. 35 cm. (13½ in.).

FIELD CHARACTERS. As for 468; indistinguishable from it unless in the hand. See Key to the Subspecies.

STATUS, DISTRIBUTION AND HABITAT. Breeds in the Maldive Islands where it is the most abundant and widespread tern. Not recorded in Ceylon or along the western coast of the Peninsula.

Extralimital. 'Islands of the western Indian Ocean from the Seychelles, Amirante and Aldabra Islands east to the Chagos Islands' (Peters).

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 468. 'Voice less loud and harsh than in the majority of the family' (W. W. A. Phillips).

BREEDING in the Maldives (Addu Atoll etc.) on small islets and coral banks with scrub. Season, June-July. Clutches laid on bare coral shingle between small lumps of broken coral or in shallow, seemingly unintentional scrapes scattered several metres from one another. Eggs, 1 or 2, mostly light stone grey, spotted, speckled and blotched with sepia to light brown, with faint secondary blotches of purplish grey or lavender. Coloration extremely cryptic on background of weathered grey coral shingle and sand. Average size of 14 eggs 39.4 × 27.44 mm. (Phillips, JBNHS 55: 567-9).

MUSEUM DIAGNOSIS. Differs from eastern nominate race in having a smaller wing and larger bill. See Key to the Subspecies for measurements.

COLOURS OF BARE PARTS. As in 468.

470. **Blackbellied Tern.** *Sterna acuticauda* J. E. Gray

Sterna acuticauda J. E. Gray, 1831? (1830-1832), in Hardwicke's Ill. Ind. Zool. 1(6): pl. 70, f. 3 (Cawnpore, India)

Baker, FBI No. 2093, Vol. 6: 141
Plate 46, fig. 19

LOCAL NAMES. In general as under 458.

SIZE. House Crow — ; length c. 37 cm. (14½ in.).

FIELD CHARACTERS. A medium-sized sea tern with dark greyish brown mantle, wings, and tail, and white underparts. Long outer feathers or streamers of the 'swallow' tail largely white. Forehead and superciliary

Summer, x c. 1

region conspicuously white; crown, nape, and a stripe from lores to behind eye black. Aply known as Bridled Tern from its face markings. In flight contrastingly white leading edge of upper wing and white on tail-feathers very conspicuous. Sexes alike.

In winter crown brown, flecked with white.

Young (immature). Above, paler brown, the feathers broadly edged white. Crown brown with greyish edges to the feathers; nape almost all brown. Black band from lores replaced with white speckled with black.

¹ Synonymized, as by Vaurie (1965). The subspecies are inseparable from nominate *anaethetus*.

58

CHARADRIIFORMES

FIELD CHARACTERS. A medium-sized, deeply fork-tailed fluviatile tern.

Adult (summer) ashy grey above, chiefly black below. Forehead, crown, nape, and crest glossy black; lores, cheeks, chin, and throat pure white. Readily distinguished from Whiskered Tern in black-bellied summer plumage by long, deeply forked tail (v. short and almost square). Sexes alike.

In winter upper part of head white streaked with black, and with a black patch behind eye. Below, white tinged with grey on foreneck and breast. Then distinguished from River Tern (463) only by smaller size and slenderer bill.

Young (immature). Above, buffy grey, the feathers edged paler buffy white and subged blackish.

For downy chick see Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident, practically throughout the Indian Union, Nepal, and both Pakistans, affecting large rivers and jheels in the plains. Less common in South India; absent in Ceylon. Occurrence west of Indus river (Las Bela, southern Baluchistan, etc.) needs confirmation. An essentially inland and freshwater tern, not found on the sea coast. Overall less common than River Tern.

Extralimital. Burma, Thailand, western Indochina.

GENERAL HABITS. Keeps in large or small flocks flying up and down placid stretches of rivers or resting on shoals and sandbanks in close-packed gatherings, all uniformly face to wind. The birds hunt methodically, flying a few metres above the surface, bill and eyes directed intently below — sometimes almost skimming the water — with slow wing-beats upwind taking advantage of the resistance for a deliberate scanning of the surface. At the end of its beat the bird turns round and shoots swiftly downwind back to the starting-point to repeat the process. The quarry is captured by plunging vertically from the air and submerging, or by lightly scooping it off the water or land.

FOOD. Mainly fish; also insects and crustaceans.

VOICE AND CALLS. A shrill *krek*, *krek* constantly uttered while flying about.

BREEDING. Colonial. Season, chiefly March and April, sometimes continuing into May — perhaps for second layings when first destroyed by floods; earlier, c. February, in S. India. Nest, a small shallow scrape, often merely a dimple, in the bare sand on sandspits and large sandy islets in rivers. Colonies, frequently of considerable size, and shared with River Terns, skimmers and pratincoles. Eggs, normally 3, sometimes 2, rarely 4, broad ovals very slightly compressed at the smaller end. Variable in ground colour from pale to dark sandy, occasionally with a greenish tinge; speckled or spotted all over with reddish or purplish brown and secondary markings of pale grey or pale purplish grey. As in all river-bed nesting birds, both the eggs and downy chicks become completely obliterated in their sandy background. Average size of 100 eggs 32.4 × 24.9 mm. (Baker). Both sexes incubate; period recorded as '15 or 16 days'. The parents shelter the eggs and chicks from the fierce sun by standing over them or sprinkling them with water carried from the river by dousing their belly feathers. To feed the incubating mate and chicks the birds (♂ only?) have been repeatedly observed to fly unnecessarily long distances to collect fish at outlying tanks, even though plenty were available in the river closer at hand.

60

CHARADRIIFORMES

STATUS, DISTRIBUTION AND HABITAT. A pelagic wide-ranging tern found sporadically far out at sea. Disperses after breeding over the Arabian Sea to the coasts of Pakistan, western India and Sri Lanka. Two records from Andaman Is. (Abdulali, JBNHS 68: 400), but probably occurs oftener than reported. Doubtless occurs off the Sind and Gujarat coasts whence specifically not yet recorded, though several once observed from ship between Karachi and Bombay, and many caught by the sailors while roosting on board.

Extralimital. Breeds on islands in the southern half of the Red Sea, northern Somali coast, Makran coast (?) and Persian Gulf. Ranges southward to Mozambique and east to western India. Also locally on islands in the China Sea from Taiwan to Malacca and eastward through the Sunda Is. to New Guinea and Australia. Ranges to Sri Lanka, Mergui Archipelago and Japan (Peters).

MIGRATION. Flocks totalling an estimated '50 to 100,000' recorded as purposefully flying N-S along the coast at Colombo, Sri Lanka, between c. 17 and 21 August, 1974, conjectured as migrating to winter feeding grounds in the southern Indian Ocean (T. W. Hoffmann, CBCN, August 1974: 132-3).

GENERAL HABITS. Gregarious and exclusively maritime. Usually found offshore, but also wanders considerable distances out to sea. Flocks follow shoals of fish, plummeting on them from a height, several birds at a time or in ones and twos, going completely under. The bird presently reappears with a silvery victim held crosswise in the bill. This is manoeuvred into position and bolted head foremost, as with a little shrug to shake off the water from its plumage, the bird wheels round to resume the slaughter, plunging again and again where the fishing is good. Flocks settle on floating buoys or rocks or ships' rigging to rest, and frequently roost at night up amongst the lifeboats.

FOOD. Mainly fish.

VOICE AND CALLS. Described as 'a rather hoarse *krek* or harsh *quik*'.

BREEDING. Breeds on islands off the Maharashtra coast, on Vengurla Rocks off Ratnagiri (c. 16°N., 73°30'E.), in Lakshadweep (Laccadives) on Balliappanni or Cherbaniani Atoll (c. 12°20'N., 71°50'E.), and reportedly on other atolls (Matthew & Ambedkar, JBNHS 61: 186), and the Maldive islands. Season, SW. monsoon chiefly June-July straggling into September. Nests colonial; in mixed colonies with Large Crested (*Sterna bergii*) and other terns: a shallow scrape or dimple in the sand. Eggs, normally 1, exceptionally 2, cream or buffy pink in ground colour, profusely spotted and speckled with Indian red, with secondary markings of lilac, 'somewhat resembling eggs of the common Moorhen' (Archer). Average size of Vengurla-collected eggs in Hume collection 43.2 × 30.1 mm. (Baker).

MUSEUM DIAGNOSIS. See Field Characters.

	Wing	Bill (from feathers)	Tarsus	Tail (outer feathers)
♂ ♀	c. 236-263	c. 41-48	c. 23	c. 126-184
(Composite of subspecies from Baker)				

COLOURS OF BARE PARTS. Iris dark brown. Bill, legs, feet and claws black.

GULLS, TERNS

61

Chlidonias hybridus

Breeding range

Chlidonias leucopterus

Breeding range

flocks well out to sea 'never within 7 or 8 miles of land' (Hume, in the Laccadives). F. N. Betts saw one in these waters resting on the back of a sleeping sea turtle (1938, *ibid.* 40: 385). Very active and clamorous both in daytime and during night on its breeding grounds as well as flocks at sea when agitated or attracted in the dark as by a well-lit passing ship. This habit coupled with the distinctive cry have earned its popular name of 'Wideawake' or 'Wideawake Tern'.

FOOD. Fish and squids obtained by plunging from a height or scooping up from the surface; flying fish caught in the air. Clear evidence of nocturnal feeding provided by a case of six undigested (recently swallowed) deep-sea fishes, *Vinciguerria luetia* (Garman), with photophores intact, regurgitated by an example which had landed on shipboard in the Pacific 3 hours after sunset. These bathypelagic fishes (fam. Gonostomatidae) only ascend to the surface from deep water in the darkness to feed (Mörzer Bruyns & Voous, 1965, *Ardea* 53 (1-2): 79).

VOICE AND CALLS. Cry described as a wild wide-wake.

BREEDING. Season in the Laccadives evidently much prolonged, c. December/January to May; on Vengurla Rocks apparently between c. April and August/September. The stormy seas just before and during the SW. monsoon (May to September) make landing on Vengurla Rocks for investigation impracticable. The length of this period suggests the possibility that unsuccessful parents may breed again at an interval of less than twelve months, as on some Pacific islands (Ashmole, 1965, *Proc. U.S. Acad. Sci.* 53 (2): 311-18). Eggs laid on the bare soil, or in a shallow depression in vast closely packed colonies ('about 3½ pairs to the square yard' in Seychelles — Ridley). Normally 1, occasionally (perhaps accidentally) 2; moderately elongated regular ovals. Coloration very variable: white to pinky white or 'yellowish pinkish stone colour' (Hume), speckled and blotched with violet or brown. Average size of 30 eggs 52.3 × 36.0 mm. (Baker). Both sexes incubate; period unrecorded.

MUSEUM DIAGNOSIS. For description of plumage see Baker, loc. cit.

MEASUREMENTS	Wing	Bill (from feathers)	Tarsus	Tail (outer feathers)

CHARADRIIFORMES

474. Sooty Tern. *Sterna fuscata nubilosa* Sparrman

Sterna nubilosa Sparrman, 1788, Mus. Carls., fasc. 3, no. 63 (Finland, *errore* = 'India Orientalis' according to Sundevall)

Sterna infuscata Lichtenstein, 1823, Verz. Doubl. Mus. Berl.: 81 (East Indies)
 Baker, FBI No. 2096, Vol. 6: 144
 Plate 46, fig. 16

LOCAL NAMES. As for 458 (all terns).

SIZE. House Crow; length c. 43 cm. (17 in.).

FIELD CHARACTERS. A medium sized black-and-white pelagic tern with conspicuously long pointed wings and deeply forked tail. Leading edge of upper wing contrastingly white; outermost elongated tail-feathers greyish white; bill and feet black.

Adult (summer). Very similar to Brownwinged Tern (471) but somewhat larger and much darker (sooty black) above. White frontal band broader but superciliary portion of it only extending to just above eye. Dark loreal stripe more oblique, reaching bill nearer to gape and extending above eye. *Below*, breast and throat white; abdomen and under tail-coverts greyish. Sexes alike.

Summer, × c. ½

In winter crown and lores speckled with white.

Young (immature). Above, sooty brown or dark grey spotted with buffy white on back and wings, broadest on scapulars and tertiaries. *Below*, somewhat paler sooty brown, whitish on lower abdomen and under tail-coverts.

STATUS, DISTRIBUTION and HABITAT. Breeds in vast numbers on the Laccadive Islands (Cherbaniani Reef). Also breeds on Vengurla Rocks off the western coast of the Peninsula (S. of Ratnagiri); reportedly in the Maldives, and probably the Andamans. Disperses over the ocean after breeding; non-breeding range insufficiently known. Vagrants (storm-blown?) have occurred far inland, e.g. Cachar (Assam), Darbhanga (Bihar), Tirunelveli (Tamil Nadu) and in the Hill zone of Ceylon. Once taken on the Konkan coast (Alibag); occasional winter visitor to coastal Ceylon. Large flocks observed at sea between Ceylon and N. Mahé Atoll (Maldives) in November; also in the vicinity of the islands at various times of the year (Phillips, 1963, JBNHS 60: 577).

Extralimital. 'Islands in the Indian Ocean (Mascarene, Seychelles), China Sea, Sulu Sea; Ryukyu Is.' (Peters).

GENERAL HABITS. A pelagic tern seldom coming to land except in the breeding season, and thought, according to M. W. Ridley (1957, JBNHS 54: 920-1), 'to feed, sleep, and even copulate in the air'! Usually seen in

64

CHARADRIIFORMES

475. Little Tern or Ternlet. *Sterna albifrons albifrons* Pallas

Sterna albifrons Pallas, 1764, in Voeg's Cat., Adumbr.: 6 (Holland)

Sterna minuta innominata Zarudny & Loudon, 1902, Orn. Monatsb. 10: 150
 (Bampur and Esposafar, Persian Baluchistan)

Sterna albifrons praeternissa Baker, Bull. Brit. Orn. Cl. 49: 39
 (Buna Island, Persian Gulf)

Baker, FBI, 2087, 2090, Vol. 6: 135, 138

Plate 46, fig. 4

LOCAL NAMES. None recorded.

SIZE. Myna ±; length c. 23 cm. (9 in.).

FIELD CHARACTERS. Distinguished from all other grey and white terns by its diminutive size.

Adult (summer) with velvety black cap, white forehead, and orange-yellow bill and feet. Sexes alike.

In winter the black cap much mixed with white, bill blackish, feet dusky red.

Young (immature). Upperparts with dark wavy bars; forehead and crown white, speckled with brownish black; nape blackish finely stippled with white.

STATUS, DISTRIBUTION and HABITAT. The species overall occurs widely but rather locally in both Pakistans, northern India east to Assam, peninsular India south to Kerala and Rameswaram I., Nepal lowlands, Ceylon, Laccadive and Maldivé Is. Ranges of the races uncertain and tentative, since besides being locally migratory the birds spread out extensively in the non-breeding season and mingle confusingly, making sight records insufficiently definitive. Affects tidal creeks, coastal lagoons and salt-pans, but chiefly rivers and freshwater jheels inland.

As presently understood *S. a. albifrons* breeds only in W. Pakistan (Makran, Las Bela) and NW. India (Gujarat — Bhavnagar), wandering down the west coast to about the latitude of Bombay.

Extralimital. 'Breeds in Europe and western Asia from the British Isles, southern Sweden . . . south to the Mediterranean, Black and Caspian Seas and Tarbagatai. Winters south to the Somali coast of Africa and to NW. India' (Peters).

GENERAL HABITS. Keeps singly or in small loose parties or flocks, working deliberately back and forth over water with quick wing-beats, bill and eyes directed below, scanning the surface for food; shooting back downwind to starting-point to repeat the manoeuvre. Often hovers over a promising spot like Pied Kingfisher (*Ceryle rudis*). Plummet with wings pulled in to seize prey below surface, or dips steeply at a tangent to pick it off the water with a backward flick of the bill as it momentarily skims over it. Observed 'dropping from a height of c. 20 feet into water only 2 inches deep' (Hingston, R.W.G., unpublished MS.). A number of birds plunging one after another, each emerging presently with a silvery fish in the bill is a fascinating sight. Flies with quicker wing-beats than the larger terns, reminiscent in silhouette of a hobby (*Falco subbuteo*).

FOOD. Chiefly small fish and crustaceans; also aquatic insects.

VOICE AND CALLS. A sharp *creek, creek* or *cree-uk* of the same tone quality as the Pied Kingfisher's *chiruk* call. Other calls described in Witherby, loc. cit.

GULLS, TERNS

65

BREEDING. In small colonies on sandbanks in rivers (Chenab, Sutlej, Punjab — Whistler) or sandy islets in jheels (Saranda, Las Bela 'in a different part to that occupied by Caspian terns etc.' — Ludlow). *Season*, chiefly May and June. *Eggs* — 2 or 3 — laid on bare sand or shingle in a shallow depression; sandy coloured, variously tinged with yellowish, greyish, or greenish, and blotched, spotted or speckled with some shade of dark brown or reddish brown. Average size about 32 × 24 mm. Both sexes incubate; period unrecorded.

MUSEUM DIAGNOSIS. See Key. In nominate *albifrons* upperparts darker than in 476 and 477. Shafts of first three primaries dark brown to brownish white. Black of crown tapering anteriorly; white of forehead touching eyes above. Legs and feet orange-yellow or yellow (Humayun Abdulali, 1964, JBNHS 61 (2): 441). For plumage phases and structure (also bionomics) see Witherby, 1941, 5: 40-3.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail central outer	Depth of fork
♂♂	164-180	27-32	15-18	43-48 75-95 (one 66)	23-50 mm.
♀♀	164-180	—	—	42-48 74-85	28-41 mm. (Witherby)

COLOURS OF BARE PARTS. Adult. Iris brown. Bill yellow, tip brown. Legs and feet orange.

476. Blackshafted Ternlet. *Sterna saundersi* Hume¹

Sterna saundersi Hume, 1877, *Stray Feathers* 5: 324, note 325 (Karachi, Sind)
Baker, FBI No. 2091, Vol. 6: 138

LOCAL NAMES. *Bondu*, *Bondu dooni* (Maldives).

SIZE. Same as 475; length c. 23 cm. (9 in.).

FIELD CHARACTERS. Indistinguishable in the field from 475 or 477. See Key and Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Little definitely known. Breeds for certain in the immediate surroundings of Karachi City, the birds arriving there about the first week in April and disappearing by beginning of September. Probably also breeds in suitable places along the Sind and Makran coasts in W. Pakistan (Ticehurst, C. B., *Jbis* 1924: 143). Non-breeding whereabouts of this population unknown. Non-breeding specimens have been collected in Gujarat (Kandla, May; Pirotan Island, July), near Bombay (Dharamtar Creek, April) and Ceylon (Karativu Island); also at Madras and in the Laccadive (Hume) and Maldivé islands. Very large numbers observed in Addu Atoll (Maldives) throughout the year; reported by the locals to breed there during April with other terns (Phillips, 1953, JBNHS 60: 577).

Affects tidal creeks and coastal lagoons; very seldom found on fresh water.

Extralimital. 'Southern coasts of the Red Sea, the Somali coast of Africa, southern coasts of the Persian Gulf to Sind' (Peters).

GENERAL HABITS, FOOD, VOICE and CALLS. Nothing specifically recorded except that 'it is a salt-water bird entirely, its local migrations presumably

¹ Awarded specific rank on account of sympatry, and different colour pattern and ecology.

GULLS, TERNS

67

but not proved. A breeding visitor to these places; whereabouts in non-breeding season unknown. Collected on Sankosh River, northern W. Bengal, in April (SDR).

Extralimital. 'Korea and Japan south along the coast of eastern China and Indochina [Viet Nam, Cambodia, etc.] and eastward through the Philippines, Celebes and Lesser Sunda Is. to the Bismarck Archipelago and New Guinea' (Peters).

GENERAL HABITS, FOOD, VOICE and CALLS. As in 475 and 476.

BREEDING. *Season*, near Bombay chiefly May and June; in Tamil Nadu and Ceylon May to August. Small to fair-sized colonies ('over 100 nests on Uttan Washi islet near Bombay'). *Eggs*, 2 or 3 laid on bare rock or in a shallow scrape in shingly soil, unlined or with a flimsy bed of grass; the clutches close together (2 or 3 feet apart) where space restricted, or widely spaced as in *saundersi* where spacious. Shape typical of terns' eggs, broad ovals very little smaller at one end than the other. Coloration variable, mostly as in nominate *albifrons*, but some eggs stone colour or beige or bluish white with a few black blotches and spots. Average size about 32 × 24 mm. Both sexes incubate; period unrecorded. On exposed sandbanks and shingle-beds eggs and hatchlings protected from fierce heat of the sun by the parents flying out and dipping their belly feathers in water before relieving each other on nest. Both eggs and newly hatched chicks (covered with greyish creamy down with a disruptive pattern of black spots) blend perfectly with the coarse sand and gravel substrate and vanish from view in an astonishing way.

MUSEUM DIAGNOSIS. Differs from nominate *albifrons* in having shafts of all the primaries glistening white. For description of plumage see Blanford, FBI (1st ed.) 4: 320.

Plate 46, fig. 11

LOCAL NAMES. *Gardoni* (Maldives); *Mahudu lūhinya* (Sinhala); *Periya kondai kōdai* (Tamil); *Tharathauri* (Lakshadweep).

66

CHARADRIIFORMES

depending on food supply. The birds come up the creeks following the shoals of fry (which abound in the nesting season) and move off again after breeding to new and better feeding grounds amongst the innumerable sandbanks of the Sind coast — places practically inaccessible to the observer' (Ticehurst).

BREEDING. In small scattered colonies. *Season* (Karachi) April-May to July-August. *Nest*, an unlined hollow, occasionally lined with shell fragments and small pebbles — sometimes an animal's hoof-print — on salt mudflats above high-tide mark, preferably on a small mound of wind-blown sand collected round a *Suaeda* plant or other obstruction. The nests widely scattered, each being 20 to 100 yards from the next. *Eggs*, almost invariably 2, pale to warm buff, with small spots and scrolls of dark brown all over, and secondary markings of violet-grey. 'Average size of 46 eggs 32.52 × 24.05 mm. Weight of clutches 15-17.5 grains (av. 16.4)' — Ticehurst. Both sexes share in incubation; period unrecorded.

MUSEUM DIAGNOSIS. Differs from *albifrons* (475) in being distinctly paler grey above. First three primaries (as.), including shafts, black and white, very contrasting. In *albifrons* usually first two primaries are black and white; occasionally the third also but in that case the black and white is not sharply contrasted. Legs yellowish brown or lemon yellow or orange in *albifrons*. Black of crown not tapering anteriorly but truncated above white forehead; the latter does not reach top of eye.

MEASUREMENTS

	Wing	Bill (from feathers)
10 ♂♂	166-174	29.5-31.5 mm.
6 ♀♀	165-173	27.5-29 mm.

COLOURS OF BARE PARTS. Adult (breeding). Iris brown. 'Bill yellow, black at tip (7.5-13.5 mm.). Tarsi and toes anteriorly and webs yellowish brown, yellower at back of tarsi and soles' (Ticehurst).

477. Whiteshafted Ternlet. *Sterna albifrons pusilla* Temminck

(Sunda Islands and the Moluccas to New Guinea = Java)

Baker, FBI No. 2088, Vol. 6: 136

LOCAL NAMES. *Muhudu lūhinya* (Sinhala); *Kādāl kūrī* — apparently general for all terns (Tamil).

SIZE. Slightly larger than 475; length c. 25 cm. (10 in.).

FIELD CHARACTERS. Indistinguishable in the field from 475 or 476. See Key and Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Sight records not definitive. Breeds for certain in Ceylon (Whistler, 1944, SZ 23 (3 & 4): 270, and Phillips MS. notes), and on Uttan Washi, a small offshore islet in the Bombay neighbourhood (Sālim Ali and Humayun Abdulali, 1939, JBNHS 40: 635 — recorded as *albifrons*, later corrected). Also on Rameswaram I., Tamil Nadu (c. 9°18'N., 79°19'E.) (Biddulph, 1938, JBNHS 40: 251) evidently this race,

68

CHARADRIIFORMES

SIZE. Pariah Kite —; length c. 53 cm. (21 in.).

FIELD CHARACTERS. A large sea tern with black crown and prominent nuchal crest, lemon yellow bill, and black legs.

Adult (summer). Lores and a band across forehead white. Crown down to eyes, nape, and a distinct nuchal crest velvety black. Neck (all round) and underparts white. Mantle grey with a lilac tinge. Tail greyish white; primaries blackish. Sexes alike.

In winter head white, lightly speckled with black on forecrown, boldly on hindcrown. Nuchal crest all-black.

Young (immature) has the upperparts dull brownish grey, with the wing-quills greyish brown.

STATUS, DISTRIBUTION and HABITAT. Resident. Breeding in West Pakistan (Astalu I. off Pasni on Makran coast; islands off the mouth of Kajhar Creek near the Sind-Kutch border), and E. Pakistan (Sunderbans). In India on the west coast (Vengurla Rocks south of Ratnagiri); and W. Bengal (Sunderbans). Also on Adam's Bridge and rocky islets off the SW. coast of Ceylon, the Laccadives, and reportedly in the N. Malé Atoll of the Maldivé Is. Probably on other suitable islands in the area. Found at one time of the year or another along the entire western and eastern seaboard. Keeps chiefly to the open sea.

Extralimital. 'Coasts of northeastern Africa and southern Asia from the Red Sea to Tenasserim . . . and Mergui Archipelago' (Peters).

GENERAL HABITS. A typical sea tern usually seen in offshore waters and often considerable distances out at sea — hardly ever even on tidal creeks — single birds or small loose parties and flocks, often mixed with *S. bergii*, scouting for prey. The birds fly a few metres above the sea with steady wing-beats, bill pointing downward, scanning the water intently. Now and again one will stop abruptly and almost double upon itself, hovering momentarily like Pied Kingfisher to investigate more closely. Prey secured by plunging from the air rather obliquely than vertically, several birds dropping one after another or more or less simultaneously as occasion offers. The bird emerges with a fish in its bill and jerks it into position before swallowing and resuming the hunt. When satiated the birds settle to rest on buoys or fishing stakes, or cluster together with gulls and other terns on rocks and sandbanks.

FOOD. Mainly fish and prawns.

VOICE and CALLS. A characteristic *chirrup*, usually when hovering to plunge. Loud clamour of screaming and chattering as typical of all terns when a nesting colony is disturbed and milling around in a rabble overhead.

BREEDING. Colonial. *Season*, April to June. *Eggs*, 1 or 2 (rarely 3?) laid in shallow scrapes in sand or on bare rock or coral, the 'nests' almost touching one another. Exceedingly variable in coloration, the ground colour ranging from white to cream or salmon-pink and even heather-purple, the markings from deep blackish brown (sometimes deep chestnut or pale reddish brown) blotches and spots to twisted scrawls resembling Arabic characters. Average size about 60 × 40 mm. Incubation period 'apparently 3 weeks to 23 days' (Baker). Vast quantities of eggs are (at least were, c. 1890) collected for food by the inhabitants of Astalu Island (as many as 7000 fresh ones in early June mentioned!), besides which they are subject to serious ravages by Sooty Gulls (*Larus hemprichii*).

GULLS, TERNS

69

MUSEUM DIAGNOSIS. For description of plumage see Baker, loc. cit., but his line 5 on p. 121 should read 'outer tail-feathers with white bases [not "lores" (sic)] and dark grey tips...'.
 MEASUREMENTS

 340-358 70-74 31 (msd.) 83-102 152-191 mm.
 (HW, SA)

COLOURS OF BARE PARTS. Iris dark brown. Bill creamy to greenish lemon yellow. Legs and feet: adult, brownish black; immature, greenish yellow irregularly blotched with black; claws horny brown.

479. Indian Lesser Crested Tern. *Sterna bengalensis bengalensis* Lesson

Sterna bengalensis Lesson, 1831, Traité d'Orn., livr. 8: 621 (Coasts of India)

Baker, FBI No. 2079, Vol. 6: 124

Plate 46, fig. 14

LOCAL NAMES. *Iam matie gerdooni* (Maldives); *Muhadu lihiniyā* (Sinhala); *Kendāi kīdāl kūrūci* (Tamil).

SIZE. House Crow ±; length c. 43 cm. (16½ in.).

FIELD CHARACTERS. Very similar to Large Crested Tern (478), q.v., only smaller and with the crown and nuchal crest wholly black down to the eyes in summer, lacking the white lores and forehead. Sexes alike.

Distinguished from Gullbilled (460) by orange bill v. black.

Winter and immature plumages differ in the same way as in 478.

STATUS, DISTRIBUTION AND HABITAT. Resident? According to Ticehurst the commonest tern of Karachi Harbour and coast-line. Occurs commonly along the western and eastern seaboard of India, Andaman and Nicobar Is., and in Ceylon waters practically throughout the year; more abundant between September and end April. Presumptively breeding on the Makran coast (W. Pakistan), Rameswaram Island, Laccadive and Maldive Is. (N. Malé Atoll), but no direct evidence as yet. A typical sea tern like the last, keeping to offshore waters, seldom seen on the coast.

EXTRALIMITAL. 'Coasts of southern Asia from the Persian Gulf to the Straits of Malacca; Sumatra, Java, Celebes' (Peters).

GENERAL HABITS, FOOD, VOICE AND CALLS. Very similar to those of the Large Crested Tern (478).

BREEDING. Nearest definitely known breeding localities, islands in the Persian Gulf, e.g. Al 'Arabiya, Buna, Warba, where season, May and June. Eggs, 1 or 2, smaller but with the same variability of coloration and markings as in 478.

MUSEUM DIAGNOSIS. For description of plumage see Baker, loc. cit.

CHICK (in down). 'Upperparts almost white with black spots on crown and ulna, and tending to run into lines on the back. Underparts pure white' (Ticehurst, Iraq).

GULLS, TERNS

71

COLOURS OF BARE PARTS. Iris dark brown. Bill black, tip horn-yellow. Legs and feet black; soles yellow (Witherby).

Genus *ANOUS* Stephens

Anous Stephens, 1826, in Shaw's Gen. Zool. 13 (1): 139. Type, by subsequent designation, *Anous niger* Stephens = *Sterna stolidus* Linnaeus

Differs from *Sterna* in having the third or fourth pair of tail-feathers longest *centra* the outermost. Bill long, slender, considerably curved towards the end of the culmen. Nostrils situated in a groove even further from the base than in *Sterna*. Tarsus very short, much shorter than middle toe without claw. Feet large; fully webbed. Wing long, first primary (as.) longest.

Genus represented throughout the tropical and subtropical seas; by two species within our area.

Key to the Species

- Wing over 270 mm.; crown grey; fourth pair of tail-feathers longest *A. stolidus*
 Wing under 240 mm.; crown white; third pair of tail-feathers longest *A. tenuirostris*

(No locality = Philippines ex Sonnerat)

Baker, FBI No. 2097, Vol. 6: 145

Plate 46, fig. 17

LOCAL NAMES. *Meranga* (Maldives); *Kerifoid* (Lakshadweep).

SIZE. House Crow—; length c. 41 cm. (16 in.).

FIELD CHARACTERS. A smoky chocolate-brown tern with white forehead passing into grey on crown and to brownish grey on neck. Wings and tail

× c. ½

blackish brown. Tail much less forked than in other terns and without the pointed 'streamers'. Sexes, and summer and winter plumages alike.

Young (immature) paler brown and without the grey cap.

STATUS, DISTRIBUTION AND HABITAT. Breeds in the Laccadives, especially Pitti atoll; possibly also in the Maldives and other islets in our seas. Overall status in non-breeding season unclear. Occurs in the Andaman, Nicobar and Maldive Islands as resident?; occasionally seen in the seas around Ceylon, and as a straggler on the west coast south of Colombo—presumably storm-tossed. Has been recorded along the Makran coast of

480. Sandwich Tern. *Sterna sandvicensis sandvicensis* Latham

Sterna sandvicensis Latham, 1787, Gen. Syn., Suppl. 1: 296 (Sandwich, Kent, England, based on the Sandwich Tern. Gen. Syn. 5: 356)

Baker, FBI No. 2074, Vol. 6: 119

Plate 46, fig. 18

LOCAL NAMES. Unrecorded.

SIZE. House Crow ±; length c. 44 cm. (17 in.).

FIELD CHARACTERS. Adult (summer). Similar to Gullbilled Tern (460) q.v., but somewhat larger. Black bill longer and slenderer, tipped with yellow. A more pronounced nuchal tuft than in Gullbilled. Sexes alike. Confusable also with Large Crested (478). (See Key.)

In winter crown white streaked with black. A black stripe from in front of eye continuing through and behind it into the black nuchal tuft.

Young (immature), like adult in winter but with a dark band on the lesser wing-coverts, and brown crescentic bars on tertiaries and tail-feathers. Primaries dark grey.

STATUS, DISTRIBUTION AND HABITAT. Winter visitor in fair numbers to W. Pakistan (Makran and Sind coasts). In India sight recorded only in Saurashtra, Gujarat (Dharmakumarsinhji, 1958, JBNHS 55: 357) where possibly frequent in winter but overlooked amongst Gullbilled Terns. Essentially a maritime species like the Crested terns.

EXTRALIMITAL. 'Breeds in the British Isles and on the North Sea, Atlantic and Mediterranean coasts of Europe; Black Sea; Caspian Sea. Winters on the coasts of northern Africa, western Africa to Cape of Good Hope; Red Sea, Persian Gulf...' (Peters).

MIGRATION. One ringed Astrakhan-Reserve, Caspian Sea 27.vii.1977, recovered Kalpitiya, Sri Lanka 24.xii.1977 (CBCN, Sept.1978: 50).

GENERAL HABITS, FOOD, VOICE AND CALLS. Similar to other sea terns, e.g. 478. Keeps to the sea coast in company with Lesser Crested and Gullbilled terns. Plunges for fish or picks up marine worms etc. from mudflats in oblique swoops.

BREEDING. Extralimital.

MUSEUM DIAGNOSIS. For description of plumages, structure, etc. (also bionomics) see Witherby, 1941, 5: 18-24.

72

CHARADRIIFORMES

W. Pakistan between Jask and Pasni, and cyclone-driven examples taken at Ormara. Like the sea terns keeps out at sea and away from the coast except when nesting.

EXTRALIMITAL. 'Breeds on tropical islands in the Indian and western Pacific Oceans from the Seychelles and Madagascar to the Hawaiian Islands and the Tuamotu Group, north to the Ryukyu and Bonin Islands, and south to N. Australia, Norfolk Island and the Tuamotu Group' (Peters).

GENERAL HABITS. Similar to the sea terns, but the birds evidently do not plunge for fish. They feed largely by following schools of small fish which are apparently being attacked by some submarine predator, picking them off as they scurry along or skip above the surface in the stampede to escape. The birds momentarily hover over the water and poise before darting downward to snatch the prey. Noddies congregate in groups at such feeding centres which break up and scatter again when the fish dive deeper. They also feed actively during bright moonlit nights. Commonly found resting on buoys, fishing stakes or bits of flotsam offshore and on the rigging of ships. Occasionally they settle on the sea, riding the water like gulls.

FOOD. Mainly small fish captured as above; flying fish caught in the air. VOICE AND CALLS. 'A low harsh croak ker-r-rk sometimes emitted in flight particularly at night' (Gibson-Hill, 1947).

BREEDING. Season, in the Laccadives (Cherbaniani Reef) February (Hume) but apparently much prolonged. Elsewhere (Seychelles, Christmas Island) April to September, mainly July-August. Nest, a small untidy layer of debris on a rock shelf, a shoddily put-together structure of sticks, straw, etc. up in the head of a coconut palm, or on a *Pandanus* or other bush; sometimes on bare shingly ground. Usually in close-packed colonies, but also individually. Egg almost invariably a singleton, roughly ovoid, slightly more pointed at one end, and with a fine matt surface. Warm off-white to very pale fawn in ground colour sparsely blotched with light grey and pale purplish grey, and with fine or coarse dark amber markings chiefly at the broad end. Average size of 10 eggs from North Keeling (Indian Ocean) 52.9 × 36.0 mm. (Gibson-Hill, 1947). Colour of yolk yellow *centra* orange in Sooty Tern (Ridley, 1957).

MUSEUM DIAGNOSIS. For detailed description of plumage see Hume, A. O. (1876, SF 4: 479); for ecology Gibson-Hill, 1947: 104-8.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	271-300	35-42	c. 25	152-176 mm. (Baker)

COLOURS OF BARE PARTS. Iris brown. Bill, legs, feet and claws black or blackish brown.

482. Whitecapped Noddy. *Anous tenuirostris worcesteri* (McGregor)

Aforaneus worcesteri McGregor, 1911, Phil. Jour. Sci. 6, sect. D: 183

(Cavilli Island, Sulu Sea)

Baker, FBI No. 2098, Vol. 6: 147

LOCAL NAME. *Meranga* (Maldives).

SIZE. Pigeon; length c. 33 cm. (13 in.).

FIELD CHARACTERS. Hardly distinguishable from 481 in the distance. A blackish brown tern with white forehead and crown, passing into ashy grey and then into dark brown on nape. Loes and chin jet black; sides of neck, throat and foreneck sooty black. Sexes alike.

Young (immature). Paler brown, but also with white cap and black loes.

STATUS, DISTRIBUTION and HABITAT. Rare straggler. Recorded as seen on occasion in the Bay of Bengal, but no recent report or specimen thence. There is a specimen from Calcutta in the British Museum (Baker). Specimens have been obtained in the Andamans (Port Blair), near the mouths of the Ganges, and at Minicoy Island in the Laccadive Group, c. 8°30'N., 73°0'E. Reported to breed (subsp.?) on the South Mahlosmadulu Atoll, Maldives Is. in November (Gadow & Gardiner, 1903). Possibly a breeding visitor there; not met with by Phillips between December 1956 and February 1957 (JBNHS 55: 212). Sri Lanka, sight record c. March (Loris xv(1), June 1979).

Extralimital. Other known breeding places Cavilli Island, Sulu Sea, Philippines, and Chagos Archipelago south of the Maldives (Ibis 1962, 104: 71). Subspecies in latter case undetermined.

GENERAL HABITS, FOOD, VOICE and CALLS. Not recorded in Indian waters.

BREEDING. Extralimital.

MUSEUM DIAGNOSIS

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail

Genus *Gygis* Wagler

Gygis Wagler, 1832, Isis von Oken, col. 1223. Type, by monotypy,

Sterna candida Gmelin

Leucanous Mathews, 1912, Bds. Austr. 2: 432. Type, by original designation,

Gygis microrhyncha Saunders

Plumage pure white. Wing long; first primary (as.) longest. Tail forked, of moderate length, less than half the wing. Bill stout and straight, longer than head. Nostril placed nearer the base than tip. Tarsus very short; toes long and the webs slightly indented.

483. Indian Ocean White or Fairy Tern. *Gygis alba monte* Mathews

Gygis alba monte Mathews, 1912, Bds. Austr. 2: 443 (Seychelles)

Baker, FBI No. 2039, Vol. 6: 148

Plate 46, fig. 5

LOCAL NAMES. *Cundu*, *Wallu dooni* (Maldives).

SIZE. Pigeon —; length c. 27-33 cm. (10½-13 in.).

FIELD CHARACTERS. An elegant, distinctive snow-white tern with long forked tail. Shafts of primaries and tail-feathers dusky. A narrow ring of black feathers round eye. Sexes alike.

484. Indian Skimmer or Scissorbill. *Rynchops albicollis* Swainson

Rynchops albicollis Swainson, 1837 (1838), Anim. in Menag.: 360 (India)

Baker, FBI No. 2100, Vol. 6: 150

Plate 45, fig. 3

LOCAL NAME. *Pānchira* (Hindi).

SIZE. House Crow ±; length c. 40 cm. (16½ in.).

FIELD CHARACTERS. A very long and pointed-winged tern-like bird chiefly blackish brown above, glistening white below. Easily identified by pied plumage, the peculiar compressed knife-like orange-yellow bill with the lower mandible projecting well beyond upper, and bright red legs. The broad white forehead and sides of face and neck (white collar) contrasting with black crown and nape, and a dark stripe down the middle of the white rump and tail (slightly forked) are further pointers. Sexes alike; female somewhat smaller.

Young (immature). Lighter brown above, scalloped with fulvous white. Forehead streaked with brown. Tail-feathers brown-tipped.

STATUS, DISTRIBUTION and HABITAT. Resident, nomadic, and also locally migratory depending upon water conditions. Fairly common in West Pakistan (Baluchistan?, Sind, Punjab, Indus system), northern India east to Assam (Ganges and Brahmaputra systems), and East Pakistan. Less common southward through Andhra Pradesh (Narbada, Tapti, Mahanadi, Godavari, Kistna rivers). Not recorded south of c. 16°N. in the Peninsula; absent in Ceylon. Confined to the larger rivers. Rare vagrant on inland tanks (once several on the lake at Mt Abu, Rajasthan — Butler, SF 5: 225) and even estuaries and inshore coastal waters (Bombay — once). Affects placid expansive reaches of rivers with sandbanks.

Extralimital. Burma and the Indochinese countries.

GENERAL HABITS. Rather tern-like. Hunts singly or in small loose parties, congregating later to rest on sandbanks in rivers in close-packed flocks, all birds sitting with face to wind. Hunts actively also during moonlit nights. Skims gracefully over placid water with quivering tips of wings held in line with body, the projecting tip of lower mandible immersed at an oblique angle, lightly ploughing the surface. The upper mandible, which is capable of much vertical movement, is raised clear as the bird beats methodically back and forth over a promising stretch of shallows along the edge of the main stream sometimes merely 3 cm. deep. On striking knife-blade edge of lower mandible, the prey slides up the tip with the momentum — rather as a tennis ball trundled along the ground runs up an inclined racket. The upper mandible is promptly snapped shut with the head jerked double under the body, the interlocking blades seizing the prey transversely in a vice-like grip. The fish is quickly flipped round through a right angle and swallowed head foremost; on dissection of bird's gizzard, small fish, all more or less same size, found 'lying neatly parallel like sardines in a tin' (Whistler).

FOOD. Mainly small fish. Stomachs frequently found to contain a small quantity of oily fluid only.

VOICE and CALLS. A nasal *kap, kap* (Whitehead). 'A yapping sound like young fox-hounds' (Mohammad Abdulla el-Husseini).

BREEDING. Season, chiefly mid February to mid April, with slight local variations. Nest, an unlined depression in the sand. In mixed colonies with

STATUS, DISTRIBUTION and HABITAT. Resident and breeds on Addu Atoll in the Maldives (Phillips, 1963, JBNHS 60: 578). Also further south in the Chagos Archipelago (Ibis, 1962, 104: 71). A specimen collected over a hundred years ago in the Bay of Bengal (Hume, 1878, SF 7: 447); no other record from elsewhere within our limits. Keeps to the open sea but apparently never at any great distance from land.

GENERAL HABITS. Similar to the Noddies', qq. v.

FOOD. Small fish. To feed the young these 'are brought home [by the adults] in neatly arranged rows in the bill' (Ridley, 1957, JBNHS 54: 924).

VOICE and CALLS. 'Raucous notes, almost a parody of a human being's laughter' uttered both during day and night (Ridley).

BREEDING. Season. On Addu Atoll (Maldives) reported to breed intermittently throughout the year; in the Chagos Archipelago chiefly May to August. Egg, a singleton, greyish white to greyish pink or buff, blotched and spotted and with squiggly lines of black or reddish brown. Average size of 40 eggs 40.2 × 30.7 mm. (Baker). No nest built, the egg being balanced in some slight depression along a branch, sometimes quite high up. It may be on the horizontal portion of the mid-rib of a curving frond of a coconut palm, or as in the Maldives, in a similar position on a banana leaf. The incubating bird does not sit on but behind the egg, covering it by fluffing out its breast feathers. On disturbance, it does not spring up but rather falls away backwards to avoid dislodging the precariously balanced egg. Both sexes incubate; period 30-32 days. Chick on hatching equipped with sharp claws which enable it to hold on to swaying substrate and avoid being blown off in a gale. (For an excellent account of the breeding biology on Cocos-Keeling Island, Indian Ocean, see Gibson-Hill, 1947.)

MUSEUM DIAGNOSIS. Bill rather large, conical, slightly bent upwards, the angle of the gonys large and projecting. Tail graduated, approaching in shape that of *Anous*; forked in the middle (Hume).

MEASUREMENTS

	Wing	Bill (from feathers)	Tail
15 ad. ♂ ♀	225-241 (av. 236)	39-44 (40.5)	102-120 mm (108) (Gibson-Hill)

COLOURS OF BARE PARTS. Iris brown. Bill black, the basal half blue. Legs dusky with the webs yellow.

Genus *Rynchops* Linnaeus

Rynchops Linnaeus, 1758, Syst. Nat., ed. 10, 1: 138. Type, by monotypy,

Rynchops nigra Linnaeus

Culmen curved; lower mandible knife-like, projecting beyond upper; flexible, truncated at the end and closely furrowed on the side with minute oblique ridges. Shorter upper mandible stouter and stronger. Nostrils elongate, near base of upper mandible and near commissure; opening in an irregular hollow. Wings very long, reaching far beyond tail at rest; first primary (as.) longest. Tail short, slightly forked. Tarsus longer than middle toe and claw; feet small, webs between the toes with concave edges.

The genus contains 3 species, one each in America, Africa and India.

River and Little terns, on exposed sandbanks in the larger rivers. Eggs usually 3, less commonly 4. Ground colour variable ranging from pale pinky buff, pale *café-au-lait*, pale salmon or stone, to greyish or greenish white; blotched and streaked with rich umber, chocolate- or reddish brown, sometimes with underlying purplish markings. Average size about 41 × 30 mm. Incubation chiefly by female, though male said to assist. Period unrecorded. Parents constantly soak their undersides in the river and splash water over the eggs and young to keep them cool. Sitting female 'constantly leaves the nest to fly round with the male' (Stanford). When first hatched, bill of downy young like that of a young tern. On alarm chicks lie down stretched out full length perfectly motionless in indentations in the 'crusted' sand, as flat as pancakes, and are very difficult to distinguish in their surroundings. Sandstorms often bury the eggs and crouching young more or less completely (Lowther, 1949).

MUSEUM DIAGNOSIS. For description of plumage see Baker, loc. cit.; for mechanics of feeding and structure of bill, Schilmdmacher, H., 1931, Orn. Monist. 39 (2): 37-41; for feeding behaviour and anatomy Zusi, Richard L., 1962, Publ. No. 3, Nuttall Orn. Club, 101 pp.

MEASUREMENTS

	Wing	Bill (from feathers) upper lower mandible mandible	Tarsus	Tail
♂ ♀	344-398	58-75 78-100	24-26	104-112 mm. (Baker)

COLOURS OF BARE PARTS. Adult. Iris brown. Bill orange-yellow, more scarlet at base, more yellow at tips. Legs and feet bright vermilion. In juvenile before bill assumes the 'scissors' shape, colour — also of feet — horny.

MISCELLANEOUS. Lowther observed from a photographing hide a downy River Tern chick run past a skimmer sitting on eggs. The skimmer left the nest and gave chase, attempting to pick it up in its feet. Succeeded at third attempt and carried it off, vigorously pursued by the parents. Eventually dropped the chick in the river while twisting and turning in the hurly-burly (Lowther, 1949).

Order COLUMBIFORMES

Family PTEROCLIDIDAE: Sandgrouse

For morphological and other details see Stresemann, L., 1927-34, Aves: 762-3; Witherby, 1940, 4: 147; Baker, 1928, FBI, 5: 260; Van Tyne, J., & Berger, A. J., 1959: 453; Meinertzhagen, R., 1964, Article 'Sandgrouse' in Thomson, A. L. (ed.) *New Diet. Birds*, London and New York.

Sandgrouse are terrestrial pigeon-like birds chiefly of sobre sandy brown coloration exquisitely patterned with disruptive black spots and vrmiculations affording them perfect camouflage in their native semi-desert environment. They have an exceptionally powerful flight, and in spite of their short legs are also good walkers and runners.

SANDGROUSE

77

Genus SYRRHAPTES Illiger

Syrrhaptes Illiger, 1811, Prodrum: 243. Type, by monotypy, *Tetrao paradoxus* Lin. Gmel. = Pallas

Distinguished by absence of hallux or hind-toe and by having the very short squat toes feathered above to the tips as well as the entire tarsus. Central tail-feathers very long and pointed. Wing long: first primary (as.) much the longest.

485. Tibetan Sandgrouse. *Syrrhaptes tibetanus* Gould

Syrrhaptes tibetanus Gould, 1850, Bds. Asia, pt. 2: pl. and text (= 6, pl. 61 of bound vol.) (Tsomoriri Lake, Ladak, Tibet)
Baker, FBI No. 1896, Vol. 5: 277

Plate 47, fig. 9

LOCAL NAMES. Kük, Käling, Käkling or Keeling (Ladakh); Kang-ga-ling, Kakali (Tibet).

SIZE. House Crow +; c. 48 cm. (19 in.).

Sole of foot, x c. 1

FIELD CHARACTERS. A sandy coloured pigeon-like but squat ground bird with a long, pin-pointed tail.

Adult (male). Above, forehead and over the crown to upper back white finely cross-barred with black. Mantle vinaceous sandy brown. Lower back and rump greyish white finely vermiculated with black. Tail rufous-chestnut with white tips; elongated central feathers greyish sandy. Face, sides of neck and throat orange-yellow. Wing-quills black. Below, foreneck and upper breast finely cross-barred with black. Rest of lower parts white.

Female overall similar but with mantle coarsely blotched and vermiculated (or barred) with black, and the barring below extending to lower breast.

Young (immature). Like female but with only faint traces of orange-yellow on sides of neck.

STATUS, DISTRIBUTION AND HABITAT. Resident and (?) altitudinal migrant; apparently descending to lower elevations locally in winter. Ladakh (Rupshu, Tso Moriri, Tsokri and Pangong Lake neighbourhoods) and Himachal Pradesh (Baralacha Pass). Just across the northern boundary of Sikkim but apparently not within. Affects barren, stony semi-desert steppes in Tibetan Plateau country between c. 4200 and 5400 metres.

Extralimital. 'Breeds in inner Asia at elevations ranging between 12,000 and 16,000 ft. from the Pamirs to Kokonor, south to Lahul and Sikkim [?]; in winter descending to somewhat lower altitudes' (Peters).

GENERAL HABITS. Terrestrial. Keeps in flocks of 10 to 30, sometimes even up to a hundred, irregularly dotted about, walking like pigeons and picking food on barren stony ground. The birds lie close and rise only when observer 50 paces or so away, settling again at a short distance. They are

♀♀	248-266			203-216 mm. (Baker)

COLORS OF BARE PARTS. Iris brown. Bill and nails bluish horny.

485a. Pallas's Sandgrouse. *Syrrhaptes paradoxus* (Pallas)

Tetrao paradoxus Pallas, 1773, Reise Russ. Reichs 2: 712 ('deserto Tatarico australiore')
Plate 47, fig. 8

The only known occurrence within our limits of Pallas's Sandgrouse *Syrrhaptes paradoxus* (Pallas) is of a female shot at Gājñer in Rajasthan on 31 December 1924 by the then Maharajkumar of Bikaner and identified by Stuart Baker (1926, JBNHS 31: 522). It is distinguished from Tibetan Sandgrouse by the presence of a black patch on the belly in both sexes, particularly noticeable in flight.

The species breeds in the steppe region of extreme SE. Russia and central Asia, winters irregularly in the plains of NE. China, and is well-known for its curious sporadic irruptions which occasionally carry it across as far as W. Europe and even the British Isles.

Genus PTEROCLES Temminck

Pterocles Temminck, 1815, Fig. et Gall. 3: 238, 712. Type, by subsequent designation, *Tetrao alchata* Linnaeus

Bill stout, small and arched above. Nostrils elongate, basal, covered by frontal plumes. Wings long and pointed: first primary (as.) longest. Tail moderate, the central rectrices sometimes lengthened to a pin-point. Tarsi feathered in front, reticulated behind. Toes short and naked; hallux present.

Genus represented throughout Africa, S. Europe, and SW. and C. Asia; six species within our limits.

Key to the Species

COLUMBIFORMES

usually tame to the point of stupidity permitting close approach even after being fired at once. They rise with the usual sandgrouse chuckle and are very noisy on the wing, constantly uttering a loud clanging double note. Like other sandgrouse they flight to water in the early morning and late dusk, though F. M. Bailey thought they had no special hour for drinking. Prefer fresh water, but will also drink brackish, as at Tsokr.

Syrrhaptes

Breeding range 1 *S. paradoxus* (SE) 2 *S. tibetanus*.

FOOD. Mostly seeds and shoots. Stomach of a specimen contained greens, seeds, elytra of beetle; very little grit (Meinertzhagen).

VOICE AND CALLS. Call in flight variously rendered as *guk-guk*, *yak-yak*, and *caga-caga*. 'Typical sandgrouse call but deeper and more musical — a pleasant *koonk-koonk* uttered by different birds in slightly varying keys reminiscent in this respect of a flock of Demoiselle Cranes' (Sálim Ali, 1946, JBNHS 46: 305).

BREEDING. No authentic eggs taken within our limits, but circumstantially breeds in Ladakh. Season, from second half of June, as just across the Sikkim frontier (Khamba Jong and Neru) and elsewhere in Tibet. Eggs, 3 laid in an unlined shallow depression on bare stony ground; oval, pale stone in ground colour covered fairly evenly with brown spots and blotches, with secondary lavender markings. Incubation (?) and tending of chicks by both parents. Incubation period unrecorded. Downy chicks fast runners. In one case attendant female did broken-wing trick, fluttering piteously along the ground for over 20 metres away from the chicks which meanwhile squatted flat and 'froze', vanishing magically from sight!

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

80

COLUMBIFORMES

486. Large Pintail Sandgrouse. *Pterocles alchata caudatus* (S. G. Gmelin)

Tetrao caudatus S. G. Gmelin, 1774, Reise Russ. 3: 93, pl. 18 (Northern Persia)
Baker, FBI No. 1892, Vol. 5: 268

Plate 47, fig. 7

LOCAL NAME. Kāzū (Baluchi).

SIZE. Pigeon +; length c. 38 cm. (15 in.) including tail c. 10-18 cm.

FIELD CHARACTERS. An overall sandy coloured terrestrial pigeon-like bird of open semi-desert country with a long pin-pointed tail. Abdomen white in both sexes. Readily distinguished on the wing from Imperial Sandgrouse (489) by general appearance, chiefly the white belly; from Spotted (488) by the single call-note v. a bisyllabic chuckle.

Male (adult). Above, head chiefly orange- or rufous-buff with a narrow black line running backward from eye. Rest of upperparts largely sandy olive-green, scantily mottled with yellow; lower back barred with black and buff. Shoulder of wing chocolate, the feathers conspicuously fringed with white. Below, chin and throat black; breast pale rufous bordered by a narrow black band above and below. Rest of underparts white.

In non-breeding plumage male resembles female but lacks the barring on the back.

Female (adult). Upperparts barred black and yellowish buff. Below, chin and middle of throat white. A band across throat dull ochraceous-buff followed by a broad black gorget and a narrow grey band. Breast pale rufous bordered by a narrow black bar above and below as in male. Rest of underparts white.

Young (immature). 'Crown, upperparts and breast yellow-buff with darker crescentic bars. Lower breast and abdomen white with a few black bars on abdomen; central tail-feathers definitely elongated but not to a pin-point' (Meinertzhagen).

STATUS, DISTRIBUTION AND HABITAT. Abundant winter visitor and/or passage migrant in autumn and spring in West Pakistan (chiefly Baluchistan, trans-Indus Sind, and the northwestern frontier districts). Less common and in smaller numbers in Punjab and Sind east of Indus R. Apparently breeds in central Makran; also perhaps locally in Punjab (oviduct egg, 8 June 1900, Mardan, Bogle, 1901, JBNHS 13: 540). Has occurred as vagrant east to Ludhiana and Delhi, south to Bikaner and Jodhpur (Rajasthan), and Deesa (N. Gujarat, c. 24°15'N.). Affects barren sandy wastes, and fallow land in partly cultivated semi-desert biotope.

Extralimital. 'Resident in northern Africa from central Morocco to Cyrenaica and south to the Sahara; resident also from Asia Minor, the Caucasus, Transcaspia, Afghanistan and NW. India, south to Palestine, Mesopotamia and Baluchistan' (Peters).

GENERAL HABITS. Terrestrial. Often arrives in winter in vast flocks literally of thousands in suitable places in the northwest. According to Hume flocks of 'tens of thousands' first seen in the far distance like a thin cloud, 'positively darkening the air when passing over' and 8, 10 or 12 falling to a single shot (1873, SF 1: 117). Apparently the numbers vary considerably locally and from year to year. The birds usually extremely wary and difficult to approach. Flight very swift and powerful said to be more so than of

its congeners; accompanied continually by the noisy and peculiar call-notes. Like other sandgrouse regularly flights long distances to drink at water-holes, etc. in the early mornings and late afternoons (occasionally also recorded at midday) wading in at the edge and sometimes even alighting directly in the shallows. Has been observed settling on water in a river far from the shore, floating high like a gull, drinking leisurely, and rising off the surface without difficulty (Magrath, 1917, JBNHS 25: 149). Like most other birds sandgrouse drink in the manner of a hen, raising the bill for

Pterocles alchata

■ Breeding range ▨ Winter 1 *P. a. caudatus*.
2 *P. a. alchata* (RE).

each gulp, and not continuously like a pigeon or horse as commonly believed. In breeding season carries water in soaked underplumage to cool the eggs or for the chicks, adults then regularly showing a mud stain on the underparts acquired while watering (Ticehurst, C. B., *Ibis* 1923: 471). At drinking time flocks pack together at a short distance from the water before walking down to drink. They also rest in the heat of the day and during the night in similar packed assemblages.

FOOD. Green leaves — clover and others — small seeds, pulse, and grain of different kinds. Gizzard usually contains a quantity of grit.

VOICE AND CALLS. Rather similar in character to those of Imperial yet distinct; uttered on the ground and in the air. Described variously as 'a ringing *catarr* or *guellar*' and 'a harsh penetrating *caa* followed by a softer *caa*'. Both sexes have an alarm-note *twoi, twoi, twoi* (Ticehurst, C. B. *et al.*, 1922, JBNHS 28: 952).

¹ For further corroboration of this habit see Tom J. Cade & Gordon L. Maclean, 1967, 'Transport of water by adult sandgrouse to their young' — *Condor* 69 (4): 323-43.

Female (adult). Upperparts dull buff streaked, spotted and barred with dark brown. Below, upper breast spotted with black; lower breast pale buff; abdomen and flanks rufous-buff closely barred with blackish.

Young (immature). Upperparts dull buff, finely vermiculated all over with thin wavy black lines. Below, chin, throat and breast buff, finely barred with blackish; abdomen and flanks dull black.

STATUS, DISTRIBUTION AND HABITAT. Common resident — also nomadic and/or locally migratory — throughout West Pakistan (abundant in parts of Baluchistan and Sind), and peninsular India (decreasingly common eastward to Bengal, southward to Madurai and Tirunelveli districts, Madras). Recorded (once) in Jammu. Absent in Assam, East Pakistan, and Ceylon. Affects barren plains and plateaux: dry stubbles, sun-baked ploughed and fallow land, and sparsely scrubbed stony semi-desert. Avoids forest and coastal tracts.

Extratropical. SW. Arabia, Iraq (?), S. Palestine, Syria. Allied races in N. and E. Africa.

GENERAL HABITS. Usually met in small scattered parties of 3 to 5 and flocks of 10 to 30 birds — exceptionally up to a couple of hundred. But where water is scarce, as in the Thar desert of W. Pakistan, vast concentrations of a thousand or more may collect to drink at a single waterhole. Shuffles along the ground on its short legs gleaning weed and grass seeds. Coloration of squatting bird remarkably obliterative in its native environment, even at a few yards' range. Has the common habit of the family of regularly sighting to water in the morning a couple of hours after sunrise, often over considerable distances. At the appointed hour flock after flock will converge from all quarters on a favourite drinking place. The first flock alights some distance from the water, and after a few minutes of sitting around or pecking for food the birds shuffle down to the edge, sometimes wading in up to their bellies. After a few quick gulps they are off again, while relays of further flocks continue to follow. In very hot weather, and less regularly, the birds also drink in the early afternoon — not at dusk as Painted and Coronetted Sandgrouse do, qq. v.

Incidentally the birds provide excellent sport with the gun as they fly to and from their watering places. Their powerful flight with rapid, steady wing-beats, and dense plumage call for straight shooting and heavy shot to bring them down.

FOOD. Vegetarian: mostly weed- and grass seeds along with which a quantity of grit is swallowed. Seeds identified include *Cyamopsis psoraloides*, *Eleusine aristata*, *Pseudanthisteria hispida*, and species of *Tephrosia*, *Indigofera*, *Panicum*, *Phaseolus* and others. (For a detailed list of seasonal stomach contents see Faruqi, Bump, *et al.*, 1960, JBNHS 57: 360-61.) Hume also mentions mustard leaves. 'Their dry droppings are very distinctive — an oblong dark part with a mushroom-like white cap' (Ticehurst).

VOICE AND CALLS. A penetrating double-note *Kut-ro* uttered in flight — not particularly loud but far-carrying — often clearly audible long before the birds come into view. 'A loud musical *gutter, gutter* in flight' (Meinertzhagen).

BREEDING. Season overall January to May, varying somewhat in different parts of the country. Chiefly March to May in northern India, January to

BREEDING. Circumstantially may breed in W. Pakistan (central Makran and Peshawar dist.). In the nearest authenticated breeding place, Iraq, season May to July. Eggs normally 3, sometimes 2, laid on dry open flat ground without any sort of nest; very variable: mostly pale creamy buff in ground colour with dark brown or red-brown primary and violet-grey secondary markings. Average size of 20 eggs 44.36 × 30.0 mm. (F. Ludlow). Incubation by both sexes; incubation period (in captivity) 21-23 days (Meade-Waldo, *Avicultural Magazine*, 1906: 219).

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

Chick (in down). 'General colour above mottled very pale buffy white, pale ginger with black tips. No definite pattern, but supercilia and coronal streak whitish. The brown down here and there has long black hair-like tips, while on the thighs the whitish down has similar white hairs. Underparts whitish to buffish white. Iris brown; bare skin round eye blue-grey; toes yellowish' (Ticehurst).

MEASUREMENTS		Wing	Bill (from feathers)	Tarsus	Tail
♂♂	213-224	c. 13-15	c. 25-29	140-190 mm.	
♀♀	194-231				

Weight ♂♂ 10-12 oz. (284-340 gm.); ♀♀ 8½-11½ oz. (c. 235-320 gm.) (Baker).
COLOURS OF BARE PARTS. Iris brown. Bill dusky green to dull brown or slate colour. Feet dirty yellow to dusky green.

487. Indian Sandgrouse. *Pterocles exustus erlangeri* (Neumann)

Pteroclorus exustus erlangeri Neumann, 1909, Orn. Monatsb. 17: 154

(El Hot, Lahej, southern Arabia)

Pterocles exustus hindusian Meinertzhagen, 1923, Bull. Brit. Orn. Cl. 43: 158

(Sambhar, Rajputana)

Baker, FBI No. 1893, Vol. 5: 271

Plate 47, fig. 4

LOCAL NAMES. *Bhāt teelār*, *Kuhar* (Hindi); *Bātubār*, *Bātubān* (Sind); *Pokurder*, *Pokundi* (Marathi); *Kāl gojāl hākki* (Kannada); *Jam polānki* (Telugu); *Kāl koudiri* (Tamil).

SIZE. Pigeon; length c. 28 cm. (12½ in.) including tail of c. 12 cm.

FIELD CHARACTERS. A yellowish sandy-grey pintailed pigeon-like ground bird of dry open plains country, with a narrow black band across breast in both sexes. In flight stout bullet-shaped body with tapering tail-end, pointed shortish sickle-like wings, and double-noted call *kut-ro* diagnostic.

Male (adult). Upperparts sandy grey and buff with dark narrow crescentic marks and coarse yellowish speckles. Cheeks, chin, and throat dull yellow; belly chocolate-black.

x c. 1

April in the Deccan; but sporadically also in other months. Nest, an unlined scrape or depression in the bare soil in open scrubby wasteland often interspersed with dry cultivation, usually unsheltered by clod or bush. Eggs, normally 3, sometimes 2, elliptical, equally rounded at both ends. Greyish to yellowish stone in ground colour with numerous spots and specks of brown scattered over the surface, and secondary markings of pale- or inky grey and lavender. Average size of 200 eggs 36.8 × 26.2 mm. (Baker). Incubation and tending of young by both sexes. Birds close sitters, often leaving nest only when intruder a metre or so away and, especially if eggs hard-set, giving the 'broken-wing' distraction display. Period of incubation reportedly 20 days.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.; for moult Ticehurst, C. B., Bull. Brit. Orn. Cl. 42: 9-11.

Chick (in down). 'General colour above golden brown with black tips, and bill passes over the head as a coronal streak (broken on forehead) to hindneck and then to the middle of the back where it divides, making the top of a "figure of eight". From base of bill another white streak passes in front of eyes, and is lost in the ear. Well-marked "figure of eight" on lower back outlined by black and enclosing coverts. Rest of crown pale ginger-brown dotted with black; underparts buffish white, darkest on the pectoral region. Bill and bare space round eyes lead-blue; iris hazel; feet dusky flesh, nails white' (Ticehurst).

MEASUREMENTS		Wing	Bill	Tarsus	Tail
♂♂	177-185	c. 26-28	17-20	c. 25	105-142 mm.
♀♀	171-177				

Weight ♂♂ 8-10 oz. (c. 227-284 gm.); ♀♀ 7½ to 8½ oz. (c. 212-242 gm.) — Baker.
COLOURS OF BARE PARTS. Iris dark brown; eyelids and orbital skin greenish yellow. Bill horny plumbeous. Feet and claws greyish brown.

MISCELLANEOUS. In 1960-2 a substantial number of Indian and Imperial Sandgrouse were introduced into the states of Nevada and Hawaii (U.S.A.) in ecologically appropriate habitat types with a view to establishing them as supplementary game birds. For a study and review of the species for the purpose of this trial introduction see Christensen, Bohl and Bump, 1964, Special Scientific Report — Wildlife No. 84 of U.S. Dept. of the Interior, Fish and Wildlife Service, Bureau of Sport Fisheries and Wildlife. Later reports show that the species has not 'taken on', and that by the end of 1965 all the birds had disappeared.

488. Spotted Sandgrouse. *Pterocles senegallus* (Linnaeus)

Tetrao senegallus Linnaeus, 1771, Mantissa: 526 (Senegal, error, Algeria accepted as type locality by Hartert, 1924, Nov. Zool. 31: 7)

(Kunaria, Kutch, NW. India)

Baker, FBI No. 1894, Vol. 5: 273

Plate 47, fig. 6

LOCAL NAMES. *Nānho kālings*, *Kara jat* (or *frī?*) *gūā*, *Gūā* (Sind); *Wāku* (Kutch); *Lūhīnk* (Baluchi).

SANDGROUSE

85

SIZE. Pigeon \pm ; length c. 36 cm. (14 in.).

FIELD CHARACTERS. Like 487, also sandy coloured overall with elongated pin-pointed tail.

Male (adult). *Above*, pale sandy buff or sandy grey. A pale ashy band from forehead encircling crown and running back over eyes down sides of hindneck to meet in front below the orange throat-patch. Scapulars and wing-coverts with paler buff spots. Tail-pins black. *Below*, throat-patch (covering cheeks, chin, throat and sides of foreneck) deep orange yellow. Abdomen to vent blackish brown; rest of underparts buff.

Female. *Above*, buff; crown and upper back spotted, lower back barred with black. *Below*, upper breast buff spotted with black. Orange throat-patch and rest of underparts as in male.

Young (immature). *Above*, sandy, the feathers with darker crescentic bars and almost vermiculated streaks; central tail-feathers barred to tips and shorter than in adult. *Below*, pale sandy with small horseshoe marks on breast and black ventral streak (Meinertzhagen).

STATUS, DISTRIBUTION and HABITAT. Mainly winter visitor to West Pakistan (Baluchistan, Sind, and NW. frontier districts), and NW. India (Punjab, W. Rajasthan, N. Gujarat [Kutch, N. Saurashtra]) sometimes arriving as early as August/September. Local occurrences and abundance, e.g. in Kutch, rather erratic and inexplicably variable from year to year and also periodically. Small numbers resident in parts of Baluchistan and Sind, and evidently breeding, but this not yet proven. Affects arid stony and sandy wastes, and salt-encrusted *pāts* in open semi-desert in preference to thinly scrubbed plains or arable land.

EXTRALIMITAL. Resident in N. Africa from Algeria to Egypt south to Sudan and Somalia; Palestine, Iraq, Arabia, Iran and Afghanistan.

GENERAL HABITS. Typical of the family. More gregarious than Indian Sandgrouse (487), usually keeping in much larger flocks, maybe of 50 to several hundred birds, in the cold weather. Very numerous where it occurs, and in areas of water scarcity literally thousands of birds may congregate from distant points at the only available water-hole or inundated depression. Their drinking habits are marked by the same regularity and punctuality as their congeners' — flock after flock repairing to water a couple of hours after sunrise and then again in the early dusk.

FOOD. Evidently less pure vegetarian than e.g. Indian Sandgrouse. In addition to grass- and weed seeds also takes quantities of insects.

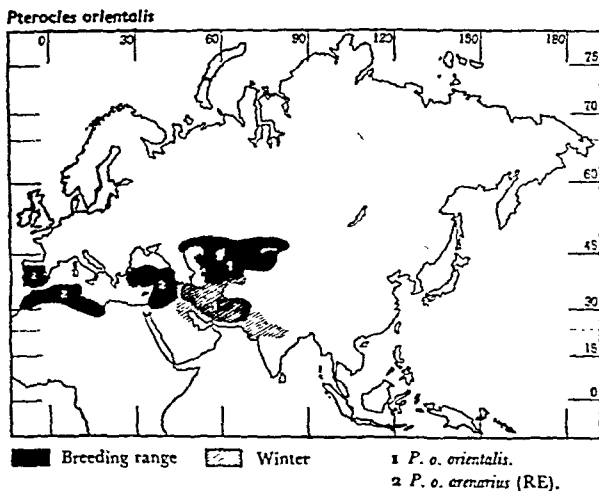

VOICE and CALLS. Distinctive and far-carrying. Various described, perhaps the closest rendering being *gū-tū-gū-tū* or *wāku-wāku*, from which the bird gets its Sindhi and Kutchi names. In the distance, when uttered by an approaching flock in chorus, the sound is curiously reminiscent of a hookah or 'hubble-bubble' being smoked! 'A liquid quiddle, quiddle' (Ticehurst).

BREEDING. Oviduct eggs taken in Sind in February, March, May and August, and the birds must doubtless breed somewhere in that area. However, as yet no complete proof of nesting within our limits. Season in Iraq chiefly June and July, but much protracted. Eggs, 3, laid on bare hard ground, e.g. dried-up marsh, or in pure desert. Colour creamy *café au lait*, blotched and speckled with reddish brown and umber-brown with a few

SANDGROUSE

87

West Pakistan (rare in lower Sind). Winter visitor (September/October to February/March) to NW. India — Punjab, Rajasthan (Thar Desert), N. Gujarat and Kutch (Little Rann environs) — locally in enormous numbers. Winter distribution somewhat nomadic, patchy and curiously erratic, both as to local occurrences and abundance from year to year, and sometimes the birds permanently forsake long-established winter habitats (e.g. in Kutch) after even a short run of aberrant seasons.

Outside the regular winter distribution, odd vagrants have strayed as far east as Lucknow, Allahabad, and Nepal, and south to Bhopal and Mysore. Affects sandy plains in arid semi-desert biotope, often at great distances from water; sometimes *pāts* or salt-encrusted waste land and fallows around canal-irrigated desert cultivation.

EXTRALIMITAL. Resident in the eastern Canary Islands; Iberian Peninsula, NW. Africa; Cyprus, Asia Minor, Palestine' (Peters). Also S. Russia, Kazakhstan, Chinese and Russian Turkestan, Transcaspia, Iran, and Afghanistan.

GENERAL HABITS. Typical sandgrouse, cf. 487. Keeps in flocks usually of 15 to 30 birds or so, but not uncommonly in vast 'swarms' of several hundred strong. Always excessively wary and difficult to approach. Flies long distances to drink ('sometimes 10-15 miles') in the morning a couple of hours after sunrise, and again in the late afternoon, before sunset, though the latter less regularly and punctually. In areas of water scarcity enormous concentrations occur at only available water, flock after flock flying in from every quarter at the appointed time. The flocks fly round once or twice high over the drinking-place before alighting, as if to assure themselves

COLUMBIFORMES

86

secondary markings of pale grey-brown or lavender. Average size of 46 eggs 40.9 × 28.4 mm. (Baker). Incubation 29-31 days.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

Chick (in down). General colour above very pale sandy yellow much paler than in *exustus* or *elchata*, with black tips to the down tufts, which on the head are not well marked except above the eyes; area round eyes pale ginger-brown. Underparts very pale isabelline; down pattern less variegated than in *exustus* and *elchata* (Ticehurst).

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail (pins)
♂♂	190-208	c. 12-13	c. 23-26	127-167 mm.
♀♀	176-197	—	—	—

Weight ♂♂ up to 12 oz. (c. 340 gm.); ♀♀ up to 9 oz. (c. 255 gm.) — Baker.

COLOURS OF BARE PARTS. Iris brown; orbital skin yellow. Bill bluish white to bluish grey or pale plumbeous, darker at tip. Feet bluish white to pale plumbeous; claws blackish.

489. Imperial or Blackbellied Sandgrouse. *Pterocles orientalis orientalis* (Linnaeus)

Tetrax orientalis Linnaeus, 1758, Syst. Nat., ed. 10, 1: 161

('In Oriente' = Anatolia ex Hasselquist)

Pterocles orientalis enigmaticus Neumann, 1934, Bull. Brit. Orn. Cl. 55: 73

(Rann of Kutch, NW. India)

Baker, FBI No. 1888, Vol. 5: 262

Plate 47, fig. 1

LOCAL NAMES. *Barchūr*, *Kurmār* (Peshawar); *Bādā bhātā* (Haryana); *Sīāh seenā*, *Chahro* (Baluchistan); *Kātingo*, *Chūr* (Sind).

SIZE. Pigeon \pm ; length c. 39 cm. (15 in.).

FIELD CHARACTERS. A typical sandgrouse (cf. 487) with pointed tail and uniformly black lower breast and abdomen in both sexes. In flight large size, partially fanned tail, black belly and contrasting white underside of wings diagnostic.

Male (adult). *Above*, sandy grey, mottled yellow and olive-blackish; upper wing-coverts ochre-yellow. *Below*, upper throat and sides of neck chestnut; lower throat black; breast grey, bounded below by a narrow black pectoral gorget followed by a broader brownish buff band and then by the black belly and flanks.

Female. Overall pinkish grey or pale fawn colour. *Above*, finely and irregularly cross-banded ('herring-boned') with black on back, and spotted with black (shaft-streaks) on head and neck. *Below*, chin and throat yellowish, bounded below by a thin black line. Foreneck ashy; upper breast spotted with black (shaft-streaks) and bounded below by a narrow black pectoral gorget. Underparts below this gorget as in male.

Young (immature) of both sexes very like adult female.

STATUS, DISTRIBUTION and HABITAT. Resident and breeding in parts of Baluchistan. Chiefly winter visitor and/or passage migrant in the rest of

COLUMBIFORMES

88

that the coast is clear, but where undisturbed the birds will often pitch directly at a steep angle. Much squabbling for positions occurs when two flocks arrive together, the birds often wading belly-deep and taking long sucks. They rise off the ground almost vertically with a peculiar rattling sound and have a very swift and powerful, pigeon-like flight with quick regular beats of the pointed wings. This combined with the bird's abundance in its accustomed habitats and the palatability of its flesh make it a coveted game bird, highly prized by sportsmen.

FOOD. Predominantly vegetarian, chiefly tiny grass- and weed seeds and shoots of desert plants. Among the seeds in stomachs and crops have been identified those of *Indigofera*, *Tephrosia*, *Heliotropium*, *Melilotus* and *Astragalus*. From a single crop an estimated 30,000 minute seeds of the last two species have been taken (Ticehurst, JBNHS 28: 949-50). Among cultivated grains species of *Phasolus*, *Panicum*, *Cyamopsis* and *Gynandropsis* have been identified. A quantity of grit is invariably present in the gizzard.

VOICE and CALLS. Various described as 'a clucking call', 'a soft double chuck or chuckle', and 'like the word *catarr* repeated several times'. Uttered on the ground while feeding or drinking, as well as on the wing, and as in other sandgrouse very far-carrying.

BREEDING. Chiefly extralimital but very probably also in Baluchistan (Quetta neighbourhood, Mastung and Pishin Plains) whence however direct proof is as yet lacking. Elsewhere (e.g. Afghanistan) season principally May and June. Eggs, 2 or 3, laid on the bare ground or in a shallow scrape in the sand, in exposed desert situations. Ground colour variable: pale buff or greenish grey to warm buff stone-colour, sometimes with a greenish tinge, with indefinite smudges, blotches and spots of various shades of brown and secondary markings of pale lavender- or purplish grey. Average size of 78 eggs 47.5 × 32.3 mm. (Baker).

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂♂	226-248	10-14	c. 24-28	101-128 mm.
♀♀	203-234	[from skull c. 20-21]	—	—

Weight 1 lb.-1 1/2 lb. 7 oz. (c. 450-650 gm.) (Baker).

COLOURS OF BARE PARTS. Iris brown; edge of eyelids lemon yellow. Bill pale to darkish plumbeous, blacker at tip. Legs and feet brownish grey or plumbeous; claws darker.

MISCELLANEOUS. In winter occurs in particularly large numbers in the Thar Desert in Bikaner district, Rajasthan. Here 'prestige' shoots used to be regularly held by the rulers of the erstwhile State for the entertainment of British Viceroy, Governors, and miscellaneous notables. Gājaner Lake has earned special fame in this connexion, but there are also several other favourite drinking-places of the birds in the area. Bags of Imperial Sandgrouse in the big shoots often exceeded 2000 birds per day to a party of 10 or 15 guns, and on one memorable occasion (in 1919 or thereabouts) all previous records were broken by the slaughter of no less than 5963 birds in the course of two successive mornings! For some days prior to these

SANDGROUSE

89

gargantuan holocausts all tanks for miles around were strictly controlled in order to keep the birds off the water and force them to concentrate only on the main source. One day before the great shoot even that was denied them, so that on the appointed morning thirst would drive them to recklessness and provide 'fine sport' to the concealed guns. Butts were strung out 50 metres or so apart along carefully determined strategic lines of the birds' flight to the water. Happily sport on this barbaric scale is no longer possible, for economic and other reasons, but reports suggest that the number of birds now visiting this area is noticeably dwindling nevertheless.

A fairly large-scale trial introduction of Imperial together with Indian Sandgrouse into the U.S.A. has recently been attempted with a view to establishing the species as supplementary game birds in appropriate habitats in the states of Nevada and Hawaii. For a good study and review of the ecology of both species made for this purpose see the Special Scientific Report (Wildlife No. 84) cited under *P. erastus* (487).

Pterocles coronatus atratus Hartert, 1902, Bull. Brit. Orn. Cl. 12: 48 (Eastern Persia)

Pterocles coronatus laevis Koelz, 1954, Contrib. Inst. Regional Exploration, No. 1: 29 (Soneri Lake, Sind)

Baker, FBI No. 1891, Vol. 5: 267

Plate 47, fig. 2

LOCAL NAME. *Kūzūgā* (Baluchistan; for any small sandgrouse).

SIZE. Pigeon —; length c. 28 cm. (c. 11 in.).

FIELD CHARACTERS. Rather like Spotted Sandgrouse (488) but smaller and lacking black belly and long pin-feathers in tail. In the air looks very white underneath; flight reminiscent of Golden Plover.

Male (adult). Above, crown pale vinous-buff encircled, except in front, by a band of bluish grey. Surrounding this band is another of ochreous yellow which expands in front to cover cheeks and throat. Chin, a streak on middle of throat, a narrow band round gape and lores, and a stripe running back on each side of forehead, velvety black. Middle of forehead and border to black on cheeks and chin, whitish. Rest of upperparts isabelle-line, spotted with buff and dusky. Below, pale buff; upper breast tinged with grey.

Female. Above, sandy buff with narrow crescentic black cross-bars; no black and white markings on face and throat. Below, paler buff finely cross-barred with black; throat yellowish speckled with black.

Young (immature). Throat whitish, otherwise much as adult female (Meinertzhagen).

STATUS, DISTRIBUTION AND HABITAT. Resident and breeding in West Pakistan (NW. frontier districts, Baluchistan, trans-Indus Sind). Numbers augmented in winter by extralimital immigrants. 'Migrant through Quetta Valley' (Williams, 1929, JBNHS 33: 611); 'in central and coastal Makran commonest small sandgrouse' (Hotson quoted by Ticehurst, 1927, ibid. 32: 74-5). Locally common in Sind. The statement by Baker in FBI

SANDGROUSE

91

491. Closebarred Sandgrouse. *Pterocles indicus arabicus* Neumann

Pterocles lichtensteini arabicus Neumann, 1909, Orn. Monatsb. 17: 152 (Lahej, Arabia)

Baker, FBI No. 1890, Vol. 5: 265

Plate 47, fig. 3

LOCAL NAME. *Gwāzang* (Baluchi).

SIZE. Pigeon —; length c. 27 cm. (10½ in.).

FIELD CHARACTERS. A small sandgrouse without pin-feathers in the tail; superficially very similar to Painted Sandgrouse (492) q.v.

Male (adult). Overall sandy buff, closely black-barred above and below, with white forehead and distinctive black and white head markings; two bold blackish bands across sandy yellow breast.

Female, close-barred above and below like male but lacking the head markings and breast bands.

Young (immature) like female but even more closely barred above and below.

STATUS, DISTRIBUTION AND HABITAT. Resident and breeding in West Pakistan (Baluchistan, NW. frontier district, trans-Indus Sind). Affects bare, stony sparsely scrubbed foothills country and dry rocky nullahs.

Extralimital. Southern Arabia to southern Afghanistan (Peters). Allied races (or same?) in north and east Africa.

GENERAL HABITS AND FOOD. Mainly as in 492 q.v.; like it also crepuscular in drinking habits. Crops of specimens examined by Ticehurst in Sind contained seeds, chiefly of *kandi* (*Prosopis spiciqera*), 'a seed other sandgrouse do not eat'.

VOICE AND CALLS. Note (as the birds came to drink after dark) 'unlike that of other sandgrouse and reminded me rather of a sparrow's "chirrup"' (Ticehurst — Sind). Call, uttered while flying up and down a watercourse, to and from water, 'a peculiar *keerp*, *keerp*' (Blanford — Abyssinia). 'A whistle, *quilo*, *quilo*, very liquid and twice repeated' as flock after flock flights overhead to water an hour or so before dawn (Archer — Somaliland).

MUSEUM DIAGNOSIS. See Key; for details of plumage, Baker loc. cit.

Differs from the nominate race (492) as follows:

<i>P. i. arabicus</i>	<i>P. i. indicus</i>
Both sexes closely barred above and below	
Tail-feathers 14	Tail-feathers 16
Male	Male
Lower throat closely barred	Lower throat plain ochraceous-buff
Feathered front tarsus plain pale buff	Feathered front tarsus spotted and barred
Black bar on white forecrown V-shaped	Black bar on white forecrown straight across
Female	Female
Chin spotted; no spots or bars on tarsus	Chin unspotted; tarsus spotted or barred

MEASUREMENTS

Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀ 166-186	c. 12-14	c. 22-27	72-77 mm. (Baker)

Wing ♂ 175-190; ♀ 172-187 mm. (Hartert).

COLUMBIFORMES

and *Game Birds* (2: 269) that 3 specimens were obtained by Col. Swinhoe so far out of its normal range as the Mhow district in Dhar [Madhya Pradesh, c. 22°32'N., 75°49'E.] seems scarcely credible. Affects barest desert with scraggy grass, and stony wastes, e.g. in the immediate vicinity of the Kirthar foothills, Sind-Baluchistan boundary.

Extralimital. Arabia, Iraq, Iran, and Afghanistan.

GENERAL HABITS. Typical of the family, cf. 487. Flights to water in the early morning till a couple of hours after sunrise in twos and threes and small packs of 6 to 20. Alights 50 to 100 metres from the water, often forming a considerable congregation, the birds pecking and sitting about for some time before gradually working down to the edge. Gait rather like partridge, more upright and quicker than of other sandgrouse. Commonly wades belly-deep, and drinks like chicken — sucking and raising bill for each gulp. After watering the parties and packs, one by one, fly straight back in the direction from which they came. Unlike Imperial, usually tame and easily approached. Perhaps less noisy than its congeners but with a quite distinctive note. Rather crepuscular: like Painted Sandgrouse comes again to drink in the evening dusk often when almost too dark to see; the calls then serve to clinch its identity.

FOOD. Chiefly vegetarian — minute seeds and shoots of desert grasses and weeds.

VOICE AND CALLS. Very different from other sandgrouse — rather soft *klā, klā, klā*, etc. uttered from the ground as well as in flight.

BREEDING. In Sind and Baluchistan season May and June. Eggs, normally 3, laid in an unlined depression in sand in barren windswept sand-dune tracts; broadly cylindrical, glossy, pale drab or yellowish stone (almost white) in ground colour, variably blotched with shades of reddish brown on underlying clouds of inky purple. Average size of 6 Baluchistan-collected eggs 43.7 × 30.0 mm. (C. H. Williams); elsewhere (e.g. Hartert quoting Dresser) the size given is closer to c. 40 × 27 mm.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♂	178-193	c. 13-14	c. 25	c. 120-132 mm.
♀ ♀	170-189	—	—	—

(Baker)

COLOURS OF BARE PARTS. Iris brown. Bill lavender-grey; feet white (Ticehurst).

PTEROCLES INDICUS (Gmelin)

Key to the Subspecies

		Page
A	No bars across hindneck.....	<i>P. i. indicus</i> (♂) 92
B	Hindneck finely barred.....	<i>P. i. arabicus</i> (♂) 91
C	Chin unspotted, tarsus spotted or barred.....	<i>P. i. indicus</i> (♀) 92
D	Chin spotted, no spots or bars on tarsus.....	<i>P. i. arabicus</i> (♀) 91

These specimens are in the British Museum (Nat. Hist.) and Mr. Ian Galbraith, Keeper of the Bird Department, has since informed us that one of them bears an original label 'Maiwand, Feb. 1881', and they all have secondary labels 'Mhow, Feb. 1881. Swinhoe'. Thus it is evident that the birds were actually collected in Afghanistan (Maiwand near Kandahar).

92 COLUMBIFORMES

COLOURS OF BARE PARTS. Iris brown; orbital skin yellow. Bill fleshy- to orange-brown. Feet orange-yellow; claws dusky.

492. Painted Sandgrouse. *Pterocles indicus indicus* (Gmelin)

Tetrax indicus J. F. Gmelin, 1789, Syst. Nat. 1 (2): 755 (Coromandel, India)

Baker, FBI No. 1889, Vol. 5: 264

Plate 47, fig. 5

LOCAL NAMES. *Pāhāri bhāt tētār*, *Bhāt bān* (Hindi); *Chāpkā* (Sagar; same as for nightjar with which confused); *Gūfā d tētār* (Mirzapur); *Palki* (Belgaum); *Kāl gajāl* *Aḷḷi* (Mysore).

SIZE. Pigeon —; length c. 28 cm. (11 in.).

FIELD CHARACTERS. Smaller than the common Indian Sandgrouse (487). Readily distinguished from it by finely close-barred plumage in both sexes and absence of pin-feathers in tail; also by stony scrub-jungle habitat (c. fallow cultivation).

Male (adult), with conspicuous head and breast markings: white forecrown cut across by a straight black band; broad tricoloured breast-band or gorget — chestnut, buff, and black. Chin, throat, foreneck and wing-shoulder unmarked yellowish buff.

Female buffy fawn overall, closely barred with black, lacking the prominent head markings and breast-band of male. Chin plain buff; throat and head finely spotted with black.

Young (immature) like adult female but even more closely barred above and below.

For downy chick see Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident and locally nomadic. The greater part of cis-Indus West Pakistan, and peninsular India from Rajasthan (Aravali Hills, etc.) and Gujarat east to Bihar and Orissa, south to Mysore and Tamil Nadu. Rare to absent in the Gangetic Plain. Absent also in deltaic W. Bengal, Assam, East Pakistan, and Ceylon. Affects bare, stony sparsely-scrubbed foothills and plateau country; avoids coastal tracts. Recorded as occurring in Jammu (Ward, 1907, JBNHS 17: 944); a specimen in Hodgson's Nepal collection but not met there by recent investigators (Biswas, 1960, JBNHS 57: 528).

GENERAL HABITS. Usually met in twos and threes or small packs of 8-10 birds frequenting rocky ground in thinly scrubbed hummocky country, or firelines in deciduous forest; especially fond of open stony burnt grass jungle. Collects in considerable numbers in favourite localities towards the end of the rains. Exceptionally large flocks of 80 to two or three hundred have been reported (Phythian-Adams (Vidarbha), Nurse (Gujarat)). Usually tame, permitting close approach, squatting motionless and trusting for safety to its remarkably obliterative coloration. Often flushing when only a couple of metres away with a noisy clatter of wings accompanied by a chuckling chirp, and pitching steeply again after a short flight of 40 or 50 metres. Runs strongly with a partridge-like gait. Flight less swift than of most other sandgrouse, attained by rapid wing-beats, the action producing a curious vibrating or '2-stroke' effect in fading light when bird going away directly

PIGEONS, DOVES

93

from observer — rather reminiscent of Grey Quail. Crepuscular in drinking habits, flying to water over long distances in the dim twilight well before dawn and then again in the gloaming till too dark for the birds to be seen unless momentarily silhouetted against the sky. Pack after pack will arrive at a tiny jungle pool till the air is thick with the traffic and the waterside a jostling mass of birds. Both when arriving and departing they keep well below the skyline, constantly uttering a distinctive *chirik-chirik* in the air and a low chuckle at the water's edge. Frequently the observer will find himself thickly surrounded by these calls and the flutter of innumerable wings without so much as catching a glimpse of a bird.

FOOD. Almost exclusively vegetarian, chiefly hard weed- and grass seeds; also some berries, and reportedly small insects like termites.

VOICE AND CALLS. A clucking *yek-yek-yek* when flushing. A distinctive, constantly-repeated *chirik-chirik* when coming to or going away from water; a soft chuckle when drinking.

BREEDING. Season not well defined; practically all months of the year, varying with local conditions; perhaps most general between March and June. Eggs, 3, rarely only 2, laid in a scrape on stony ground under protection of a small bush or grass clump; ellipse-shaped, cream to salmon-buff in colour with primary blotches and specks of some shade of brownish red and secondary markings of inky grey or lavender. Average size of 88 eggs 35.8 × 25.0 mm. (Baker). Both sexes incubate; period undetermined.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.; for differentiation from the confusingly similar Closebarred Sandgrouse, under 491.

Chick (in down). 'Uniform earthy brown' (Baker).

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	158-184	c. 13-15 [from skull 16-18]	c. 23-25	80-101 mm.

Weight 6-8 oz. (c. 170-227 gm.) — Baker.

[Wing 9 ♂♂ 166-180 (once 188, once 208); 8 ♀♀ 166-176 mm. — SA.]

COLOURS OF BARE PARTS. Iris brown; naked circumorbital skin pale yellowish green. Bill orange-brown. Tarsus (unfeathered hind portion) and feet dull yellow or greyish leaf-green; claws brownish orange to dark brown.

Family COLUMBIDAE: Pigeons, Doves

For morphological and other details see Stresemann, E., 1927-34, *Ates*: 760-2; Witherby, 1940, 4: 129-30; Baker, 1928, FBI 5: 178; Van Tyne, J., & Berger, A. J., 1959: 454; Goodwin, D., 1964, article 'Pigeon' in Thomson, A. L. (ed.), *New Dict. Birds*, London and New York.

* Typified by the Blue Rock Pigeon which in its numerous domestic breeds is universally known.

PIGEONS, DOVES

95

SIZE. Pigeon ±; length ♂ c. 42 cm. (16½ in.) including tail of c. 21 cm. (8 in.); in ♀ tail shorter, c. 18 cm. (7 in.).

FIELD CHARACTERS. Overall yellowish green with a long pin-pointed tail and two conspicuous yellow bars in the black wings.

Male (adult). *Above*, with a broad greyish olive-green collar on hindneck. *Below*, greenish yellow, the breast washed with orange-pink; under tail-coverts cinnamon, margined with whitish.

Female duller, with no greyish olive hind collar or orange wash on breast, and much shorter tail.

STATUS, DISTRIBUTION AND HABITAT. Resident and locally nomadic depending upon food supply — fruiting of favourite forest trees; throughout the Himalayas from terai level to c. 1800 metres, Kumaon to easternmost NEFA including Nepal, Sikkim and Bhutan. Also hills of Assam south of Brahmaputra R. (Khasi, Cachar, Naga, Mizo, etc.); Manipur and East Pakistan. Not rare in the Assam plains in the Surma and Brahmaputra valleys. Affects tall tree forest.

Extralimital. Chin Hills, Burma south to Tenasserim. Other races in the Indochinese countries.

GENERAL HABITS. More or less as common to all green pigeons, cf. 503. Exclusively arboreal but sometimes descending to the ground to drink, and regularly at salt-licks to pick the earth. Keeps in flocks of 10 to 30 birds or so, well to the tops of lofty forest trees, clambering about and feeding amongst the fruit-laden twigs and foliage, a deceptive resemblance to parakeets then heightened by the long pointed tails. The birds are perfectly camouflaged amongst the green leaves and become completely obliterated from view while they 'freeze' on suspicion; the unexpected numbers that will tumble out of a tree on the report of a gun is often quite amazing, while others still continue to remain frozen within. Flight swift and direct accompanied by a metallic whirring sound. In common with other green pigeons, and hawks, has the habit of sitting with fluffed plumage on the topmost bare twigs of a towering forest tree on chilly mornings to catch the first rays of the sun before commencing the day's feeding. They are rather stupid birds and even after being fired at, a flock will return to the same tree again and again within a very short time.

FOOD. A variety of berries and drupes, some of astonishingly large size, swallowed entire.

VOICE AND CALLS. A range of mellow, rather wandering musical whistles very similar to those of the Wedgetailed (494) roughly rendered as *ko-kle-ci-ci-ci-illli-illli-lla*.

BREEDING. Season, chiefly April to June. *Nest*, a sketchy platform of twigs high up in a bush or bamboo clump — sometimes a leafy forest tree. Eggs, 2, white, typical of pigeons'. Average size of 100 eggs 31.7 × 23.8 mm. (Baker). Both sexes incubate; period undetermined.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit. A character there omitted is the broad black band across the central tail-feathers in male.

Crocopus Bonaparte, 1854, Compt. Rend. Acad. Sci. Paris 39: 973. Type, by original designation, *Columba phoenicoptera* Latham.

Sphenocercus G. R. Gray, 1840, List Gen. Bds.: 57. Type, by original designation, *Columba eyura* Temminck.

Distinguished by yellowish green plumage, often with patches of lilac or chestnut on the mantle and one or two bright yellow wing-bars. Wings long and pointed, the primaries variously notched or scalloped in the different species. Tail also various: partially rounded, wedge-shaped, or pin-pointed. Tarsus stout and very short, considerably shorter than middle toe without claw; feathered on upper portion; soles of feet expanded, fleshy and pad-like, much broader than the toes themselves — an adaptation for exclusively arboreal life.

493. Pintailed Green Pigeon. *Treron apicauda apicauda* Blyth

Treron apicauda 'Hodgson' = Blyth, after May 1846 (1845), Jour. Asiat. Soc. Bengal 14 (2): 854 (Southeastern Himalayas and hill ranges of Assam — common at

Darjeeling)

Baker, FBI No. 1840, Vol. 5: 199

Plate 49, fig. 5

LOCAL NAMES. *Hār'il* (all green pigeons), *Kēkhā* (Hindi, Bengal); *Bōr hāithā* or *hāithāk* (Assam); *Deorep galou* (Cachar); *Sang pong* (Lepcha).

96

COLUMBIFORMES

♀ ♀ have shorter tails, c. 150-175 mm.

Weight ♂♂ 6½-9 oz. (c. 185-255 gm.); ♀ ♀ up to 7 oz. (c. 200 gm.) — Baker.

COLOURS OF BARE PARTS. Iris lake red; bare ocular area blue. Bill cobalt-blue, distal half of upper mandible green. Legs and feet crimson.

494. Kokla or Wedgetailed Green Pigeon. *Treron sphenura sphenura* (Vigors)

Vinago sphenura Vigors, 1832 (1831), Proc. Zool. Soc. London: 173 (Himalayas) Restricted to Simla-Almora area by Titchhurst (*Ibis* 1924: 472)

Baker, FBI No. 1841, Vol. 5: 200

Plate 49, fig. 1

LOCAL NAMES. *Kōklā*, *Kēkhā* (Hindi); *Hāithā*, *Bōr hāithā* or *hāithāk* (Assam); *Kēku*, *Kuh-fo* (Lepcha); *Deorep gadzba* (Cachar); *Keiral* (Simla).

SIZE. Pigeon; length c. 33 cm. (13 in.).

FIELD CHARACTERS. Overall yellowish green, similar to 493 but without central 'pins' to the long tapering (wedge-shaped) tail.

Male (adult). *Above*, crown tinged with orange-rufous. A variable amount of maroon on back and scapulars. *Below*, chin and throat yellow; breast pale orange-pink.

Female. Like male but lacking rufous on crown and maroon in upperparts.

Young (immature) like female, but duller and darker.

For description of fledged nestling see Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident — partly nomadic and altitudinal migrant depending upon local food supply. The entire lower Himalayas from Kashmir through Nepal, Sikkim, and Bhutan to extreme eastern NEFA, from plains level to c. 2500 metres. Also Assam hills south of Brahmaputra R. including the Nagas and those of E. Pakistan. Recorded as 'never seen or heard of' in Manipur (Higgins, 1934, JBNHS 37: 302) but probably occurs. Chiefly affects broad-leaved hill forest of oak, elm, alder, etc.

Reported from Pachmarhi, Madhya Pradesh as 'a' very rare visitor; seen and heard (April) 'by a competent and reliable observer' — B. B. Osmaston (1922, JBNHS 28: 458). But this needs confirmation since there is no other record of its occurrence in India south of the given distribution.

Extralimital. Chin Hills, Burma south to Tenasserim. Other races in Malaya and the Indochinese countries.

GENERAL HABITS. Usually keeps in small flocks of 6 to 15 birds or so, to the higher trees; common and numerous in the more open forests. Common summer visitor to most Himalayan hill stations and upland valleys. Flocks, frequently found in association with Pintailed Green Pigeon, the remarkably beautiful whistling calls and general behaviour of the two species being almost identical. The birds clamber about among the leafy fruit-laden twigs of forest trees, hanging upside down or sideways to get at the berries and frequently swinging out for one out of reach with the agility of a trapeze acrobat. They commonly descend to the ground at salt-licks to pick pellets of the salty earth. Flight swift, noisy and rather undulating.

FOOD. Exclusively frugivorous: drupes and berries of forest trees (e.g. *Ficus* and *Myrica* spp.), swallowed entire. Is very partial to mulberry (*Morus*) in hill orchards.

VOICE and CALLS. Almost indistinguishable from the Pintailed species (493) q.v., a series of rich mellow whistles 'of over 20 notes' (Osmaston). The birds can be easily decoyed by an imitation of their calls.

BREEDING. *Season*, April to June, sometimes prolonged into July/August. *Nest*, the characteristic flimsy twig structure of all pigeons built high up in a sapling or leafy forest tree; in the hills commonly in spruce firs c. 6 metres or so up, close to the trunk. *Eggs*, 2, also typical of pigeons — white, elliptical, fine-textured and smooth-surfaced. Average size of 200 eggs 31.5 × 23.1 mm. (Baker). Both sexes incubate; period given as '18 to 19 days' (Doddsworth) needs checking. Baker's statement that it has 'two or more broods per year in Assam and Bengal' also requires confirmation.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

'Nestling' [age?]. *Above*, dull green, slightly brighter on the head, upper tail-coverts, scapulars, lesser and median wing-coverts. Greater coverts dull green, edged on the extremities of the outer webs with pale yellow forming a wing-bar. Winglet, primary coverts, and primaries blackish, the majority of the last very faintly edged on the outer webs with pale yellow. Secondaries also blackish, edged on outer webs with pale yellow; tertiaries dull green. *Below*, throat, breast and upper part of abdomen pale grey, the feathers edged with greenish yellow; abdomen and vent fluffy yellowish white; thigh-coverts pale fluffy grey tipped with dark green; under tail-coverts dull green broadly edged with pale yellow.

Iris brown; orbital skin very dull blue. Bill light fleshy brown with a tinge of blue at base of lower mandible. Tarsi and feet fleshy brown, the former with a tinge of dull blue on their upper extremities. Soles of feet very pale fleshy brown; claws horny brown, darker at tips (Doddsworth, JBNHS, 22: 800-1).

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	169-187 (av. 176.5)	c. 17-19	c. 17-19	114-139 mm. (Baker, in part)

Weight (winter) 2 ♂♂ 212, 214 gm. (SA).

COLOURS OF BARE PARTS. Iris, outer ring buffy pink to bright crimson, inner ring pale ultramarine blue; orbital skin pale lavender or smalt blue. Bill pale dull smalt blue or greenish blue; cere and tip brighter and more blue. Legs and feet coral-red, cherry-red or deep crimson.

495. Thickbilled Green Pigeon. *Treron curvirostra nipalensis* (Hodgson)

Toria Nipalensis Hodgson, 1836, *Asiat. Res.* 19 (1): 164 (Nepal)
Baker, FBI No. 1838, Vol. 5: 196
Plate 49, fig. 4

LOCAL NAMES. *Daorep buku gajao* (Cachar); *Thoria* (Nepal).

SIZE. Pigeon —; length c. 27 cm. (10½ in.).

General proportions and coloration confusingly like *Treron p. phayrei* (499); distinguished from it as follows: cere considerably reduced making corneous portion of bill (rhamphotheca) almost reach forehead; large bare circumorbital patch; absence of orange on breast; prominent scarlet gape and cere.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	124-146	c. 14-15	c. 18-19	84-95 mm. (Baker)

COLOURS OF BARE PARTS. Adult. Iris, outer ring golden yellow to orange-red, inner ring deep blue; orbital skin vivid verdigris-green. Bill pale yellowish, greenish, or leaden white darker and greener at tip, brilliant coral-red round base and gape. Legs and feet deep lake-pink to coral-red.

TRERON POMPADORA (Gmelin)

496. Greyfronted Green Pigeon. *Treron pompadora affinis* (Jerdon)

Vinago affinis Jerdon, 1840, *Madras Jour. Lit. Sci.* 12: 13
(West coast of the Indian Peninsula)
Baker, FBI No. 1831, Vol. 5: 188
Plate 49, fig. 3

LOCAL NAMES. *Podi pācheha pācurdmu* (Telugu); *Chāndīrāyān* (Malayalam).

SIZE. Pigeon —; length c. 28 cm. (c. 11 in.).

FIELD CHARACTERS. A small green pigeon with red legs.

Male (adult). *Above*, forehead, crown and nape ashy grey; back and scapulars chestnut-maroon; rest of upperparts olive- or yellowish green. Shoulder of wing (median and greater coverts) black; a broad yellow wing-band. Middle pair of tail-feathers olive-green. *Below*, greenish yellow, the upper breast faintly tinged with orange or pink; under tail-coverts cinnamon.

Female olive-green, lacking the chestnut mantle and orange wash on breast; shoulder of wing less black and mixed with grey; under tail-coverts buffy white, more or less streaked with green. May be confused with ♀ Orangebreasted (501) but middle tail-feathers olive-green (c. slaty) diagnostic.

FIELD CHARACTERS. A small green pigeon with chestnut-maroon mantle, grey- and olive-green tail and a prominent yellow wing-bar. The thick bright red and greenish bill and vivid green bare orbital skin are leading clues for recognition.

May be confused with the similar-looking Ashyheaded Green Pigeon (499), but the bare patch round eye, and brilliant scarlet gape and cere are diagnostic.

Male (adult). *Above*, forehead ashy grey, forecrown darker grey; back, scapulars and lesser wing-coverts chestnut-maroon. Rest of upperparts including central tail-feathers above olive-green. Outer tail-feathers grey above with a black cross-band; black below with a very broad grey tip. *Below*, yellowish green; flanks darker green with white edges to the feathers; under tail-coverts pale cinnamon.

Female lacks chestnut on mantle and has whitish under tail-coverts with dark green broken bars.

Young (immature) like female, but whole plumage initially very grey and dull; male acquires a little maroon on the mantle at first moult. Iris pale grey-brown; orbital skin livid grey; basal portion of bill dull pink.

STATUS, DISTRIBUTION and HABITAT. Resident, subject to local movements governed by food supply: the Himalayas from western Nepal eastward through Nepal, Sikkim, northern Bengal (the duars) and Bhutan to extreme eastern NEFA, from plains level to at least 1500 metres. Also Assam hills south of Brahmaputra R. (Garo, Khasi, Cachar, Naga, Mizo, etc.); Manipur and E. Pakistan. Affects well-wooded country and forest.

Extralimital. Burma, Thailand, and Indochinese countries. Other races in Indonesia.

GENERAL HABITS. Goes about in flocks of 10 to 40 birds or so, often congregating in large numbers to feed on fruiting trees such as *Ficus* in season. Descends to the ground to drink; Stuart Baker frequently found it feeding on wild strawberries and berries of other ground plants. Flight and other behaviour not specifically different from other green pigeons, cf. 504. Roosts at night up in leafy trees or bamboo thickets, the birds sitting clumped in twos and threes or small groups along horizontal culms or bushy twigs.

FOOD. Exclusively fruits and berries, the numerous species of wild fig (*Ficus*) providing the staple.

VOICE and CALLS. In addition to a series of mellow whistles (not specifically described), has a hoarse note sounding like *goo-goo* constantly uttered by the birds while jostling for positions in the feeding tree.

BREEDING. *Season*, principally late April to early June. *Nest*, a flimsy pad of twigs in the forking leafy branch of a small tree or on a horizontal bamboo culm, at moderate heights; occasionally two or three nests within a few metres of each other. *Eggs*, 2, typically white and elliptical. Average size of 200 eggs 28.7 × 22.6 mm.; according to Baker Assam eggs average smaller. Both sexes take part in nest-building and incubation; incubation period c. 14 days (Baker).

MUSEUM DIAGNOSIS. Wing long; primaries slightly pointed; third primary (as.) deeply and widely notched or scalloped on inner web. Under tail-coverts long; tail very slightly rounded. For details of plumage see Baker, loc. cit.

Young (immature) male like adult female but acquires a certain amount of maroon on the upperparts, more especially on the lesser wing-coverts, at the first autumn moult (Baker).

STATUS, DISTRIBUTION and HABITAT. Resident, subject to some local and altitudinal movement governed by food supply (fruiting seasons). Western and southwestern India — the Western Ghats complex (including the Nilgiris, Palnis, and associated hill ranges) — from about lat. 20°N. southward through western Mysore (Malnaad) and Kerala. Affects forest and well-wooded country in evergreen and wet deciduous biotope; lowlands and up to c. 1200 m. altitude.

GENERAL HABITS. Not significantly different from other green pigeons. Usually keeps in small flocks of up to a dozen or so; sometimes large congregations on fruiting trees. Flocks commonly seen at sunrise, and also in the late afternoon before retiring to roost, perched among the topmost branches of tall leafless trees on the edge of jungle, uttering their soft whistling calls. On coffee plantations in Mysore and Kerala this pigeon along with the Emerald Dove is often reported flying headlong into the whitewashed walls of shady bungalows and outhouses and getting killed.

FOOD. Fruits and berries, mainly figs of the various *Fici* and drupes of *bēr* (*Zizyphus* spp.); salt mud at licks.

VOICE and CALLS. A series of soft rich whistles up and down the scale very like that of the Southern Green Pigeon (504) but somewhat higher in key.

BREEDING. *Season*, mainly December to March. *Nest* as in other green pigeons — a flimsy platform of twigs in a moderate-sized tree; an exceptional one recorded as high as c. 13 m. *Eggs*, 2, elliptical, white. Average size of 24 eggs 28.1 × 22.0 mm. (Baker). Both sexes share nest-building and incubation; incubation period 12-14 days, but not accurately determined.

MUSEUM DIAGNOSIS. See Key; for further details of plumage Baker, loc. cit. Longer feathers of under tail-coverts cinnamon coloured; shorter lateral ones yellowish white with greenish ashy bases.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	140-154	c. 19-20	c. 20-24	84-88 mm. (SA)

Weight 1 ♂ 151 gm. (SA).

COLOURS OF BARE PARTS. Iris: outer ring bright pink, inner ring lapis blue. Bill: cere and lower mandible near gape yellowish green, rest of bill pale grey; mouth yellowish grey-pink. Legs and feet dull magenta or plum colour; claws horny grey; soles yellow.

497. Pompadour or Ceylon Greyfronted Green Pigeon. *Treron pompadora pompadora* (Gmelin)

Columba Pompadura Gmelin, 1789, *Syst. Nat.* 1 (2): 775 (Ceylon)
Baker, FBI No. 1829, Vol. 5: 185

LOCAL NAMES. *Dala gyye*, *Sipadurā* (Sinhala); *Pācheipadā* (Tamil).

PIGEONS, DOVES

101

SIZE. Pigeon —; length c. 28 cm. (c. 11 in.).

FIELD CHARACTERS. As for the South Indian race *efnir* (495) q.v., but differs in having the forehead and sides of head greenish yellow, the grey confined only as a patch on crown. Under tail-coverts buff (c. cinnamon).

Female may be confused with ♀ Orangebreasted Green Pigeon (502) but has the middle pair of tail-feathers olive-green above (c. slaty grey).

STATUS, DISTRIBUTION and HABITAT. Race peculiar to Ceylon. Common resident. Abundant in forest areas throughout the lowlands and ranging up into the hills to c. 1200 m.; subject to local migrations. Largely replaced by the orangebreasted species (502) on the sea coast.

GENERAL HABITS, FOOD, VOICE and CALLS. Nothing specifically different from 496 and other green pigeons.

BREEDING. Starts, December to June, and in September; chiefly April and May (Phillips). Nest and eggs as in 495. Average size of 22 eggs 28.7 × 22.6 mm. (Baker).

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

Differs from the southwest Indian race *efnir* (496) in both sexes having the forehead yellow, the crown last pure (greenish) grey, and the under tail-coverts of a different colour. These are white with a faint creamy or yellowish tinge, and with a variable amount of greenish ashy speckling or barring on the feathers. (In *efnir* the longer under tail-coverts are cinnamon, the shorter lateral ones yellowish white with greenish ashy bases.) Bill slightly longer than in *efnir*.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	145-151	21-23	21-23	91-97 mm.
♀♀	141-152	21-23	21-24	88-95 mm. (HW)

COLOURS OF BARE PARTS. As in 496. 'Iris carmine-red with an inner ring of cobalt; eyelids glaucous green. Bill glaucous green, paling to bluish at the tip. Legs and feet purple-red' (Baker).

499. Nepal Greyfronted Green Pigeon. *Treron pompadora cinnamomea* Rand & Fleming

Treron pompadora cinnamomea Rand & Fleming, 1933, Fieldiana, Zool., Chicago, 34 (19): 201-2 (Batal, Nepal)
Not in Baker, FBI

LOCAL NAMES. Not recorded.

SIZE. Same as 496. Pigeon —; length c. 28 cm. (c. 11 in.).

FIELD CHARACTERS. As of the ashyheaded *pompadora* (499), q.v.; not distinguishable from it in the field. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Terai of west-central Nepal (range undefined), in heavy forest.

GENERAL HABITS, FOOD, VOICE and CALLS. Not specifically described; presumably as in other races.

BREEDING. See under 499.

PIGEONS, DOVES

103

c. 12 m. up in main fork of a leafless tree right out in the middle of a meadow with the sitting bird ludicrously conspicuous (Berts, 1947, JBNHS 46: 681). Average size of 200 eggs 27.5 × 21.8 mm. (Baker). Both sexes share in building the nest and incubation; period believed c. 14 days, but needs confirming.

MUSEUM DIAGNOSIS. See Key; for details of plumage Baker, loc. cit.

MEASUREMENTS

Wing ♂♂ 143-163; ♀♀ 145-160 mm. Weight 4.5 oz. (c. 115-140 gm.), sometimes up to 7 oz. (c. 200 gm.) — Baker.

♂♀ Bill (from skull) 17-20; tail 80-87 mm. (SA).

COLOURS OF BARE PARTS. Iris: outer ring pink, inner ring pale blue; orbital skin bluish. Bill French grey, somewhat darker at base. Legs and feet lake-red.

500. Andaman Greyfronted Green Pigeon. *Treron pompadora chloroptera* Blyth

Treron chloroptera Blyth, 1840, Jour. Asiat. Soc. Bengal 14: 832 (Nicobars)
Baker, FBI No. 1832, Vol. 5: 183

LOCAL NAMES. None recorded.

SIZE. Slightly larger than 499; Pigeon ±. Length c. 30 cm. (12½ in.).

FIELD CHARACTERS. As of the ashyheaded *pompadora* (499). See Museum Diagnosis, but 'is large as the Indian Green Pigeon (503, 504) and looks very much like it in the field' (Abdullah, JBNHS 61: 523).

STATUS, DISTRIBUTION and HABITAT. Resident. Race peculiar to the Andaman and Nicobar islands. Common in South and Middle Andamans. Affects tall evergreen forest.

GENERAL HABITS. As of the other races. Often seen feeding in parties of 6-10 or larger flocks on fruiting trees in forest or clearings. Like other green pigeons they gorge themselves to such an extent that when a shot bird falls to the ground the turgid crop frequently bursts open with the impact, expiring and scattering the contents.

FOOD. Wild figs (*Ficus* spp.) and various drupes and berries swallowed entire, including some of very large size.

VOICE and CALLS. A series of mellow musical whistling notes described by W. Davidson as 'very like but more powerful' than those of *Treron p. efnir* (495).

BREEDING. Starts, from indirect evidence of gonads of collected specimens c. February to June; but probably not well-defined. Nest and eggs unknown.

MUSEUM DIAGNOSIS. Male differs from ♂ *T. p. pompadora* (499) as follows: Forehead pure grey; lesser wing-coverts green (c. chestnut), darker and less yellow than neck. Green of upperparts more yellow except on central pair of rectrices. Chestnut-maroon mantle as dark as in *T. p. efnir* (496). Under tail-coverts dark green, merely tipped with yellowish. Bill very large, equally long with that in the other insular race (of Ceylon), but much coarser than in the other races, or even in *T. c. nipalensis* (463).

102

COLUMBIFORMES

MUSEUM DIAGNOSIS. Separated from *pompadora* (499) on character of brighter coloration with yellow of throat and orange of breast more intense. Green of hindneck, breast and abdomen duller and less greyish.

MEASUREMENTS

Wing 2 ♂♂ 156-157; 4 ♀♀ 153-164 mm. (Rand & Fleming).

COLOURS OF BARE PARTS. As in 499.

499. Ashyheaded Green Pigeon. *Treron pompadora pampori* (Blyth)

Oreophaps pampori Blyth, 1862, Jour. Asiat. Soc. Bengal 31: 344 (Toungboon, Burma)
Baker, FBI No. 1839, Vol. 5: 186

LOCAL NAMES. *Chilla kharil* (Bengal and E. Pakistan); *Chilla kharil* (Assam); *Dareh* (Cachar); *Israigan* (Naga); *Wahaly* (Kuki).

SIZE. Pigeon —; length c. 28 cm. (c. 11 in.).

FIELD CHARACTERS. A small green pigeon with red legs, very like 496.

Male (adult). Above, crown and nape dark ashy grey; forehead paler. Sides of head greenish yellow, sharply demarcated from grey crown, as is also green hindneck from grey nape. Back and scapulars chestnut-maroon; rest of upperparts olive- or yellowish green. Wings black with a broad yellow band. Middle pair of tail-feathers olive-green. Below, chin, throat, and sides of neck greenish yellow; upper breast conspicuously orange; rest of underparts olive-green tipped with buff on lower flanks. Under tail-coverts cinnamon.

Female lacks the chestnut mantle and orange breast. Under tail-coverts buff broadly mottled with dark green. Differentiated from the very similar ♀ of the orangebreasted species (501) by the green middle tail-feathers (c. slaty).

Young (immature) male like adult female but acquires a certain amount of maroon on the upperparts, more especially on the lesser wing-coverts, at the first autumn moult (Baker).

STATUS, DISTRIBUTION and HABITAT. Resident, subject to some local and altitudinal movement governed by food supply (fruiting seasons). Common and locally abundant: West Bengal (recorded south to Calcutta), Assam north and south of Brahmaputra river, and eastward through NEFA; Manipur; East Pakistan — from plains level to c. 1500 m., normally below 1000 m. Affects forest and well-wooded country in evergreen and wet deciduous biotope. How far west this race extends towards Nepal (*cinnamomea*) remains to be determined.

Extremal limit. Burma south to Tenasserim, Thailand and the Indo-Chinese countries. Other races in Indonesia.

GENERAL HABITS, FOOD, VOICE and CALLS. Like other green pigeons, cf. 496, 504 — gregarious, sometimes in large flocks of over 200 birds; frugivorous and arboreal, occasionally descending to the ground to drink or visit salt-licks.

BREEDING. Starts, March to early July, mainly April and May. Nest (twig platform) and eggs (2, white, elliptical) as typical of the family. Nests placed fairly low down in moderate-sized trees, bamboo clumps or cane brakes, often with no attempt at concealment. One recorded in Assam

TERON BICINCTA (Jerdon)

Key to the Subspecies

Larger; wing over 150 mm.....*T. b. bicincta*
Smaller; wing usually under 150 mm.....*T. b. leggii*

501. Indian Orangebreasted Green Pigeon. *Treron bicincta bicincta* (Jerdon)

Treron bicincta Jerdon, 1840, Madras Jour. Lit. Sci. 12: 13

(Sea coast south of Tellicherry)

Treron bicincta [sic] *prodermine* Robinson & Kloss, 1921, Jour. Fed. Malay States

Mus. 10: 293 (Koh Lak, southwestern Siam)

Baker, FBI No. 1834, Vol. 5: 191

Plate 49, fig. 6

LOCAL NAMES. Generally for all green pigeons *Kharil* (Hindi); *Kharil* (Assam); *Pampora pampora* (Telugu); *Manjariyana* (Malayalam).

SIZE. Pigeon ±; length c. 29 cm. (11½ in.).

FIELD CHARACTERS. Overall olive-green, similar to Greyfronted (496) but

Male (adult) lacks grey on head and chestnut-maroon mantle. Below, underparts yellowish green with a band of lilac across upper breast followed by orange on lower breast. Under tail-coverts cinnamon edged with pale yellow on the outer and longest feathers. Tail slaty grey above with a broad blackish subterminal band (except on central pair of rectrices), black below with a grey tip.

Female similarly olive-yellow above, yellowish green below but lacking the lilac-and-orange breast. Under tail-coverts pale dull cinnamon with greenish mottling. May be confused with females of *pompadora* species but tail pattern diagnostic: middle tail-feathers above slaty grey in *bicincta*, green in *pompadora*.

Young (immature) like female but duller and darker.

STATUS, DISTRIBUTION and HABITAT. Resident with the normal seasonal local movements. Widely distributed in the evergreen and moist deciduous biotopes. Not uncommon in the U.P. terai and bhabar and the lower

¹ These include 1 from Car Nicobar and 5 from S. Andamans, the latter identified by Abdullah (JBNHS 61: 523) as *andamanis* (Richardson), a controversial race.

Himalayas (to c. 1500 m.) eastward through Nepal, Bengal duars, and Assam north and south of Brahmaputra R.; Manipur and E. Pakistan. Records rather patchy, but doubtless occurs more generally. In the Peninsula, West Bengal, Chhota Nagpur and southward along the Eastern Ghats in the appropriate biotopes. Western Ghats and associated hill ranges (normally plains level and up to 1000 m. or so) from Kerala northward through Mysore to about the latitude of Belgaum (16°N.); possibly further north like the Greyfronted (496) but records lacking. Curiously enough once procured as a vagrant in Sind (Karachi) (Eates, K. R., 1938, JBNHS 40: 330). Affects forest and well-wooded country inland as well as in the coastal tracts.

Extralimital. Burma, Thailand, Malay Peninsula and South Vietnam. Other races in Ceylon, Java, and Hainan.

GENERAL HABITS. Gregarious, frugivorous, arboreal; not specifically different from other green pigeons, e.g. 496, 504, qq. v. Often associates with them while feeding in fruit-laden trees, which is chiefly in the morning and late afternoon.

FOOD. Drupes and berries. The figs of the numerous species of *Ficus* form the staple diet of fruit pigeons as of most other frugivorous birds.

VOICE AND CALLS. The characteristic series of modulated mellow wandering whistles. 'A pleasing low subdued gurgling note' (H. Stevens—Assam). But described by another competent observer (J. Davidson—Kanara) as 'hoarse, not like the musical notes of *Treron phoenicoptera* or *T. p. effinis*'!

BREEDING. Seasons overall March to September, perhaps most general April to June. *Nest*, the characteristic pigeon structure—a flimsy platform of interlaced twigs, placed in a moderate-sized tree or cane-brake some 2-8 metres up. *Eggs* 2, white, elliptical, also typical of the family. Size c. 29 x 23 mm. Both sexes share in building the nest and incubation; period c. 12-14 days.

MUSEUM DIAGNOSIS. Differs from the race *leggi* of Ceylon, q.v., only in being larger. For details of plumage see Baker., loc. cit.

MEASUREMENTS	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	153-164 (once 170)	c. 12-13	c. 23-25	91-110 mm. (Baker)

COLOURS OF BARE PARTS. Adult: Iris outer ring pink to crimson, inner ring bright ultramarine to deep blue; eyelids and orbital skin bright lavender blue. Bill pale blue or pale green, the basal half darker and brighter. Legs and feet deep coral-red to deep crimson; soles paler; claws horny brown. In young (both sexes), as in other green pigeons, iris watery pale brown; eyelids and orbital skin livid. Legs and feet dull crimson.

According to Baker the double-coloured iris is acquired at the first autumn moult, but is much less vivid than in the adult.

FIELD CHARACTERS. A stout green pigeon with a red shoulder-patch and yellow legs. Very similar to 504 but with a markedly greenish yellow forehead, and grey lower breast, belly and flanks instead of uniform bright yellow.

Young (immature) like adult but minus the shoulder-patch.

STATUS, DISTRIBUTION AND HABITAT. Resident, wandering locally with fruit-ripening. West Pakistan and northern India from c. 73°E. long. (Lyallpur, Punjab) south through E. Rajasthan and eastward along the Himalayan foothills and Gangetic Plain (including Nepal lowlands) through Bihar, northern Orissa, W. Bengal, Assam north and south of Brahmaputra R., Manipur (?), and E. Pakistan. Southern boundary uncertain and confused owing to difficulty of interpreting frequent occurrence of both races together. Birds from Gwalior district, Madhya Pradesh (c. 26°N., 78°E.) belong to the southern race *chlorigaster* (Whistler, JBNHS 41: 477), whereas both subspecies have been reported as common and procured together around Pachmarhi, M.P. (c. 22°29'N., 76°26'E.) (B. B. Osmaston, ibid. 28: 458), and Ambala Cantonment, Punjab (c. 34°54'N., 76°57'E.) (Jones, A. E., ibid. 28: 1006). Furthermore, Jones found the southern *chlorigaster* 'very common in one locality c. 3500 ft. in the low hills south of Kasauli [c. 30°54'N., 76°57'E. — Simla district] where only the nominate race would be expected! Further investigation is desirable. Affects dry- and moist deciduous forest with a sprinkling of *Ficus* and other fruiting trees. Also groves of such in the open countryside, around villages and cultivation, and in rambling jungly gardens and roadside avenues.

Extralimital. Other races extend the species to Burma, Thailand and the Indochinese countries.

GENERAL HABITS, FOOD, VOICE AND CALLS. As of 504, q.v.

BREEDING. Season, chiefly March and April; sometimes continuing into May and June or even later. *Nest* and *eggs* as in 504, q.v.

Primaries, x c. 1

MUSEUM DIAGNOSIS. See Key to the Subspecies and Field Characters; for details of plumage Baker, loc. cit.

MEASUREMENTS	Wing	Bill (from feathers)	Tarsus	Tail
	184-200	19-20	c. 25-26	110-118 mm. (Baker)

Females are rather smaller, Wing 180-168 mm.

COLOURS OF BARE PARTS. As in 504.

502. Ceylon Orangebreasted Green Pigeon. *Treron bitorquatus leggi* Hartert

Treron bitorquatus leggi Hartert, 1910, Nov. Zool. 17: 193 (Ceylon)
Baker, FBI No. 1835, Vol. 5: 192

LOCAL NAMES. *Beta goya*, *Sipachura* (Sinhala); *Pachekhi parā* (Tamil).

SIZE. Pigeon \pm ; length c. 29 cm. (11½ in.).

FIELD CHARACTERS. As of 501, q.v. An olive- and yellowish green pigeon with bright orange breast in male and no chestnut-maroon mantle.

Female may be confused with female of Greyfronted (497), but has slaty grey middle tail-feathers instead of green.

STATUS, DISTRIBUTION AND HABITAT. Race peculiar to Ceylon. Abundant but local throughout the forest areas of the low-country Wet and Dry zones, chiefly near the coasts. Subject to local migrations from district to district following fruit-ripening.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in the Indian race (501). According to Legge, it drinks regularly at about 7 in the morning and 4 in the afternoon, descending to the margin of a stream or water-hole for the purpose. Gait on ground rather clumsy with the tail held high.

BREEDING. Season, December to May, also July to September; but chiefly December. *Nest* and *eggs* as in 501, the latter measuring 'about 28 x 22.5 mm.' (G. M. Henry).

MUSEUM DIAGNOSIS. Differs from the nominate Indian race (501) only in being smaller; there is no appreciable difference in colour.

SIZE. Pigeon; length c. 33 cm. (13 in.).

504. Southern Green Pigeon. *Treron phoenicoptera chlorigaster* (Blyth)

Vinago chlorigaster Blyth, 1843, Jour. Asiat. Soc. Bengal 12 (1): 167, note
(No locality = Indian Peninsula)
Baker, FBI No. 1828, Vol. 5: 184

LOCAL NAMES. For all green pigeons, *Hārid* (Hindi, Bengali); *Pāchcha pākha*, *Pāchcha gūrd* (Telugu); *Pāchekhi parā* (Tamil); *Pisara* (Marathi).

SIZE. Pigeon; length c. 33 cm. (13 in.).

FIELD CHARACTERS. A stout arboreal pigeon, chiefly olive-green and ashy grey above, uniformly bright yellow below, with a lilac patch on wing-shoulder and a conspicuous yellow band across the blackish wings. Readily distinguished from all other Indian green pigeons by its yellow (i.e. red) legs. Sexes more or less alike; female somewhat duller, with a less pronounced shoulder-patch.

Young (immature) like adult but minus the shoulder-patch.

STATUS, DISTRIBUTION AND HABITAT. Resident, wandering locally with fruit-ripening. All peninsular India, including southern Rajasthan and Gujarat, roughly south of the Gangetic Plain (south of range of Bengal Green Pigeon) but boundary between the two races undefined (cf. 503). Rare vagrant to Ceylon (low-country Dry zone near Jaffna etc.). Affects dry- and moist-deciduous forest with a scattering of *Ficus* and other fruiting trees. Also groves of such on the open countryside, around villages and cultivation, and in rambling jungly gardens in towns, and roadside avenues.

Extralimital. Allied races in Burma, Thailand, and the Indochinese countries.

GENERAL HABITS. Almost exclusively arboreal descending to the ground only occasionally to drink or to pick earth at salt-licks; rarely also to feed on ground crops (see under Food). Gait on ground rather clumsy, with the tail held well up. Keeps in flocks of 5-10 birds or so, sometimes congregating in very large numbers to gorge themselves on ripe banyan or peepul figs (*Ficus*) in company with other green pigeons, hornbills, barbets and suchlike frugivorous species. The birds deftly clamber amongst the fruit-laden twigs like parakeets, clinging sideways or upside down and swinging out to reach a distant berry with the agility of a trapeze acrobat. When such a tree is approached the green pigeons deliberately 'freeze', and in spite of their large size become completely obliterated among the surrounding foliage till a little inadvertent movement by one here and another there betrays their presence. All the while the frozen bird will be peering intently at the intruder through a tiny gap between the leaves, as can clearly be seen through the binocular. The unsuspected numbers that will tumble out of a fig-laden banyan or peepul tree on the report of a gun is often quite amazing; but the birds soon return in twos and threes and small parties till the foliage is once more a jostling, quarrelling mass of guzzling green pigeons. They stuff themselves so greedily that the impact of a flying bird falling to shot often bursts the turgid crop, exposing and scattering the contents. Twelve complete banyan figs have been removed from a single crop! They feed chiefly in the mornings and afternoons doing regular rounds of their favourite trees, and can then provide excellent sport. Decent bags can be made by two or three guns placed in strategic positions as the

PIGEONS, DOVES

109

birds fly back and forth between the trees. Flight swift and direct, accompanied by a loud metallic clatter when suddenly flying out of a tree. Like all green pigeons has the habit of perching, in couples and small parties, on the topmost branches of dead trees to sun themselves, especially at sunrise and in the late afternoon.

FOOD. Drupes, berries, and wild figs of numerous kinds. Among the most commonly recorded are nearly all species of *Ficus* [especially *F. bengalensis* (banyan), *F. religiosa* (peepul), *F. glomerata* (guler), and *F. benjamina*]; *Zizyphus jujuba* (bêr), *Z. oenopia*, etc., *Eugenia jambolana* (jamun), *Terminalia* spp. (myrabolams), *Buchanania latifolia* (charoli), *Bridelia hamiltoniana*, and *Lantana aculeata*. Specimens have been shot with their crops stuffed with 'peas' (*Cicer*?) (Briggs, JBNHS 37: 386).

VOICE and CALLS. A series of modulated mellow musical whistles of rather human quality; very similar to call of Orangebreasted (*T. bicincta*) but louder and in a lower key.

BREEDING. Season March to June, occasionally a month or two earlier or later; mainly March and April. Nest, characteristic of the family, a flimsy platform of interlaced twigs in a moderate-sized tree, concealed among the foliage. On outskirts of forest, near villages and in gardens; often in same tree as holds a Black Drongo's nest, the birds obviously taking advantage of the protection from nest-robbers like crows and tree pies afforded by these bold and vigilant guardians. Eggs, 2, white, elliptical and glossy. Average size of 40 eggs 31.8 × 24.6 mm. (Baker). Both sexes share nest-building and incubation; period undetermined.

MUSEUM DIAGNOSIS. See Key to the Subspecies and Field Characters; for details of plumage Baker, loc. cit.

MEASUREMENTS

(SA, HW)

COLOURS OF BARE PARTS. Iris outer ring pink, inner bright lapis blue. Bill pale French grey, basal portion including cere greenish; mouth greyish pink or greyish yellow. Legs and feet bright chrome yellow; claws French grey.

505. Ceylon Green Pigeon. *Treron phoenicoptera phillipsi* Ripley

Treron phoenicoptera phillipsi Ripley, 1949, Proc. Biol. Soc. Wash. 62: 9

(Nilgala, Uva, Ceylon)

Not in Baker, FBI

LOCAL NAMES. As for other Ceylon green pigeons, cf. 497, 502.

SIZE. Pigeon ±; length c. 30 cm. (12 in.).

FIELD CHARACTERS. As of 504; somewhat smaller but not distinguishable from it in the field.

STATUS, DISTRIBUTION and HABITAT. Race peculiar to Ceylon. Resident in the low-country Dry zone. 'Appears to be confined to and fairly plentiful

PIGEONS, DOVES

Under tail-coverts dull rufous-brown..... <i>D. a. nicobarica</i>	113

506. Northern Green Imperial Pigeon. *Ducula aenea sylvatica* (Tickell)

Columba sylvatica Tickell, 1833, Jour. Asiat. Soc. Bengal 2: 581 (Borabhum)

Baker, FBI No. 1847, Vol. 5: 208

Plate 48, fig. 9

LOCAL NAMES. *Dinkul* or *Dookul*, *Sonā kāhātār*, *Bādā hārāl* (Hindi); *Pagema*, *Porgema* or *Pargomba* (Assam); *Dūkūl* (Nepali, in Nepal); *Hūkūl* (Nepali, in Bengal duars); *Dookuruma* (Cachar); *Inukuru* (Naga).

SIZE. Crow; length c. 43 cm. (17 in.).

FIELD CHARACTERS. A large arboreal fruit pigeon, pinkish grey overall with bright metallic bronzy green back and tail (above), and chestnut-maroon under tail-coverts. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Resident; locally abundant, moving about with ripening of wild fruits. Nepal (?) and eastern U.P., eastward through Bihar, Orissa, W. Bengal, Assam and E. Pakistan. Not met with in Manipur (Higgins, JBNHS 37: 302). South to lat. 20°N., the arbitrary boundary proposed by Whistler (ibid. 38: 675) between this and the peninsular form (507). Birds from Orissa and northeastern Andhra Pradesh may well pass for either race. Affects evergreen and moist-deciduous biotope — plains and foothills normally up to c. 300 metres, occasionally to 600 m. Partial to secondary jungle with a scattering of large *Ficus* and other wild fruit trees.

Extralimital. Burma to central Tenasserim, northern Thailand, Indo-chinese countries.

GENERAL HABITS. Keeps singly or in pairs and parties of 5 or 6, sometimes joining up in small feeding flocks up to 20 or so in large fruit-laden trees; seldom in larger numbers like the smaller green pigeons (*Treron*). Gentle and sociable, not blustering and quarrelsome like them while feeding. Has the common green pigeon habit of sunning itself with fluffed plumage on the leafless tops of tall trees in the early morning and before sunset. Flight swift and powerful in spite of the seemingly leisurely wing-beats; accompanied by a noisy clattering of the wings when first launching out of a tree. Flies high and well above the tree-tops when birds commuting between favourite feeding places. Commonly descends to the ground to drink and pick earth pellets at salt-licks. The male has a spectacular seesaw aerial display during the breeding season, reminiscent of the Roller (*Coracias*) and also the Blackbellied Finch-Lark (*Eremophila*), very similar to that of Jerdon's Imperial Pigeon (511), q.v. He also has a bowing display, as common to many pigeons, consisting of a movement in which the head

110

COLUMBIFORMES

in a small area of open [dry deciduous] forest country around Bibile and Nilgala, in the lowlands to the south-east of Uva hills' (Phillips).

GENERAL HABITS, FOOD, VOICE and CALLS. As in the south Indian race (504).

BREEDING. Not yet reported.

MUSEUM DIAGNOSIS. See Key to the Subspecies. Differs from *chlorogaster* in being smaller, with duller more greenish yellow nape, and duller more greyish green back and wings. Vinous shoulder-patch also duller and slightly darker. Below, breast and abdomen dull greenish yellow suffused with greyish green. Lemon-yellow of neck and underparts confined only to a submental spot, and to a patch about thighs and vent.

MEASUREMENTS

	Wing	Bill (from feathers)	Tail
4 ♂♂	163-167	c. 18-19	97-100 mm.
4 ♀♀	160-169	c. 17-18	95-104 mm.

(SDR)

COLOURS OF BARE PARTS. 'Iris (both sexes), inner ring blue, outer carmine; eyelids bluish grey. Bill pale bluish white. Legs chrome yellow' (Phillips).

GENUS DUCULA Hodgson

Ducula Hodgson, 1836, Asiat. Res. 19: 160. Type, by monotypy, *Ducula insignis* Hodgson

Muscadivora Schlegel, 1872, Dier. K. zool. Genoot. Amsterdam: 209. Type, by subsequent designation, *Columba aenea* Linnaeus

Myristicivora Reichenbach, 1852, Nat. Syst. Vög.: 26. Type, by original designation, *Columba littoralis* Temminck = *C. bicolor* Scopoli

Contains three species of large arboreal fruit pigeons — one with some bronzy green in plumage, one without, and one with very peculiar pied white and black coloration. Fleshy padded soles of feet less expanded than in *Treron* but broader

Sole of foot of *D. a. sylvatica*, × c. 1

than in *Columba*. Bill slender and long, with a long soft basal portion (cere) and a short horny tip (rhamphotheca). Caeca absent as in *Treron*, but both ambiens muscle and oil gland present as in *Columba*.

112

COLUMBIFORMES

is lowered quickly on to the breast so that the crown and nuchal region is frontally presented.¹

FOOD. Exclusively frugivorous. *Ficus* figs the staple, but most other wild fruits eaten. Nutmegs (*Myristica*) a favourite item; swallowed entire, the mace being digested and the nutmeg voided later through the mouth. Gape, lower mandible (which is wider at base than upper) and gullet enormously extensible and capacious, capable of negotiating fruits of up to c. 4 cm. diameter with ease.

VOICE and CALLS. Of several deep, resounding, rather ventriloquistic notes *uück-uück-uoor*, or *uück-uoor-uoor-uoor-uoor* ending in a peculiar prolonged rollicking which sounds singularly like jeering laughter!

BREEDING. Season overall March to June, aberrantly somewhat earlier or later; principal months April and May. Nest, a skimpy unlined platform of interlaced twigs through which the contents often visible from below; placed up in a leafy sapling in forest, usually under c. 10 metres from the ground. Eggs, normally 1, rarely 2, white, elliptical, slightly glossy. Average size of 22 eggs 45.4 × 33.5 mm. (Baker). Both sexes share nest-building and incubation; incubation period undetermined.

MUSEUM DIAGNOSIS. Differs from the peninsular Indian and Ceylon race *pusilla* (507) only in being cinclally larger. See Key to the Subspecies; for details of plumage — Baker, loc. cit.

MEASUREMENTS

♂♀ Wing 212-254 mm. In northern birds seldom under 224 mm.; Bengal and Orissa birds seldom under 220 mm. — Baker.

In ♂♀ from Eastern Himalayas: Wing 232-248 mm.; bill (from skull) 31-34 mm. — Whistler.

COLOURS OF BARE PARTS. Iris deep red, maroon-red, or crimson. Bill white at tip, bluish white in the centre, purplish red on basal half and cere. Legs and feet dull purple-red to lake red, rarely deep coral-red; claws reddish horny brown.

507. Southern Green Imperial Pigeon. *Ducula aenea pusilla* (Blyth)

Carpophaga pusilla Blyth, 1849, Jour. Asiat. Soc. Bengal 18: 816 (Nilgiris)

Baker, FBI No. 1848, Vol. 5: 209

LOCAL NAMES. *Mēhā nīla gya*, *Māila gya* (Sinhala); *Periya furā* (Tamil); *Kakarani gūre* (Telugu); *Mēsi pūru*, *Porgema* (Malayalam).

SIZE. Same as 506; length c. 43 cm. (17 in.).

FIELD CHARACTERS. As of the northern race 506 q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident; locally common, moving about with ripening of wild fruits. Ceylon and peninsular India north to 20°N. lat., the arbitrarily fixed boundary between it and 506. In the Peninsula chiefly in the Eastern and Western Ghats [north to near Bombay (Bassein, c. 19°20'N. lat.) — JBNHS 40: 377] and associated hill ranges in appropriate biotope; in Ceylon in the low-country Wet and Dry zones.

¹ For a discussion on its significance in phylogeny, see Goodwin, Derek, 1966, *The Auk* 83 (1): 117-23.

PIGEONS, DOVES

113

Affects evergreen and moist-deciduous plains and foothills forest, normally to c. 300 metres; somewhat higher with availability of food. Partial to secondary jungle dotted about with large *Ficus* and other wild fruit trees.

GENERAL HABITS, FOOD, VOICE AND CALLS. Same as in the northern race (506). In Ceylon the birds collect in flocks of 6 to 30 or more after the breeding season and appear to have regular roosting places whence they issue in the morning to their feeding grounds, often several miles away (Parker, H., 1881, SF 9: 481), flying high above the tree-tops. Among food items other than *Ficus* figs and nutmegs (*Myristica*), specifically recorded are berries of the Marking Nut or Bibba (*Semecarpus anacardium*) and buds of mangroves (*Avicennia* spp.).

BREEDING. Season, in south India (Kerala, Mysore, etc.) principally February to June; in Ceylon December to May, chiefly during December. Nest—a flimsy platform of twigs, and eggs—normally a singleton, white, smooth, elliptical—as in 506. Average size of 7 eggs (Kerala and Ceylon) 43.1 × 34.1 mm. (Baker).

MUSEUM DIAGNOSIS. Differs from the northern *syliatica* (506) only in being clinically smaller; see Key to the Subspecies.

MEASUREMENTS

♂ ♀ Wing 200–220 mm. Ceylon birds do not exceed 216 mm. and most are under 210 mm.—Baker.

8 specimens from Ceylon, Kerala, and Mysore give

	Wing	Bill (from skull)	Tarsus	Tail
3 ♂♂	210–214	31–32	28–32	131–140 mm.

COLOURS OF BARE PARTS. As in 506.

508. Nicobar Green Imperial Pigeon. *Ducula aenea nicobarica* (Pelzeln)

Carpophaga insularis Blyth, 1858, Jour. Asiat. Soc. Bengal 27: 270 (Nicobar Islands).

Nomen nudum

Carpophaga aenea var. *nicobarica* Pelzeln, 1865, Reise 'Novara' Zool. Th. 1: 105, Vog. (Nicobars). Restricted by Abdulali to Car Nicobar, 1967, JBNHS 64: 164 Baker, FBI No. 1849, Vol. 5: 210 (= *insularis*)

LOCAL NAMES. None recorded.

SIZE. Jungle Crow; length c. 47 cm. (18½ in.).

FIELD CHARACTERS. A large stout arboreal fruit pigeon, very similar to 506 but purer grey overall with dark metallic bluish- or purplish green back and tail (above), and dingy brown under tail-coverts. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Race peculiar to the Nicobar group of islands south of the Ten Degree Channel. Has been procured on the following by Hume (SF 2: 262): Comorta, Nancowry, Katchall, Trinkat, Bompoka, Teresa, Tillanchang, Treis, Trak, Pili Milu, Chowra, Meroe, Batti Malv and Kondul; and on Car Nicobar and Great Nicobar by Abdulali (JBNHS 61: 525). Resident; possibly moving back and forth between islands not too widely separated. Common and abundant to the

PIGEONS, DOVES

115

VOICE AND CALLS. 'A loud *goo* and sometimes a more guttural *groo*, uttered once, twice or thrice.' Abdulali also considered this species probably 'responsible for a deep *whoom*, often in answer to one calling *gr-groo*, the first *gr* resembling the beginning of a hiccup' (ibid.).

BREEDING. Season, February to May; aberrantly somewhat earlier or later. Nest and eggs as in 506 with which Andamans birds were hitherto included.

MUSEUM DIAGNOSIS. Slightly larger than the north Indian race 506. Differs also in being greener above, with the red coppery bronze less brilliant. Forehead and throat whiter; under tail-coverts deeper chestnut-maroon.

MEASUREMENTS

Wing 13 ♂♂ 222–257 (av. 236); 8 ♀♀ 212–240 (av. 227) mm.

Tail 5 ♂♂ 155–161 (av. 157.6); 4 ♀♀ 137–146 (av. 142.25) mm.

(Abdulali)

COLOURS OF BARE PARTS. As in 506.

509. Pied Imperial Pigeon. *Ducula bicolor* (Scopoli)

Columba bicolor Scopoli, 1786, Del. Flor. et Faun. Insubr., fasc. 2: 94

('Nova Guinea', i.e. New Guinea)

Baker, FBI No. 1850, Vol. 5: 211

Plate 48, fig. 10

LOCAL NAME. *Kaluia* (Car Nicobar).

SIZE. Pigeon +; length c. 41 cm. (16 in.).

FIELD CHARACTERS. A uniquely coloured large arboreal fruit pigeon: overall creamy white with sharply contrasting jet black flight feathers and broad tail-tip. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Abundant resident in the Nicobars but not so generally distributed as *D. a. nicobarica*; possibly wandering to the smaller islands only in search of food. Rare in the Andamans, possibly only a seasonal visitor; also in Great Coco, and Barren Is. (Hume). Fairly common on Narcondam where may be resident (B. B. Osmaston). Affects mangrove swamps and tall evergreen forest near the shore.

Extralimital. 'Philippines, eastward to the Aru Islands and islands west of New Guinea' (Peters).

GENERAL HABITS. Keeps in small parties to high tree-tops, forming into large flocks of 50 or 60 birds where food is plentiful. On some islands abundant to the point of swarming and remarkably tame. On Treis I. Hume's party bagged 50 together with a smaller number of *D. a. nicobarica* in a single fusillade! (c. 1874, SF 2: 84), and they were equally plentiful on Trak I. Reported even now to be very numerous and tame on some of the less disturbed islands of the Nicobar group. Very conspicuous on the wing against background of dark trees, but coloration amazingly obliterative when bird perched high up within the foliage canopy with patches of sunlight filtering through the dense leaves. Flight strong and direct, accompanied by a loud clatter of wings when launching out of a tree. Has the same bowing display as *Ducula aenea* (506), q.v. Aerial display, if any, not known.

114

COLUMBIFORMES

point of swarming on some of the islands not yet subjected to heavy deforestation for human settlement. Affects lofty evergreen forest.

GENERAL HABITS, FOOD. As in 506 and the other races, q.v.

VOICE AND CALLS. A deep low *coo* (Sewell); '(1) a deeper and longer *ghoom* than in *andamanica*, (2) a *koo-o* followed by a *kukku kukku-kukku* more like an owl than a pigeon' (Abdulali).

BREEDING. Very little information. Season, evidently February and March. Apparently the only nest known was a loosely put together platform of twigs 'built on a dried-up fruit branch in a coconut palm c. 20 ft. from the ground' (Davison, SF 2: 263). It contained a single white egg measuring '1.9 × 1.39' inches (= 48.2 × 34.8 mm.).

MUSEUM DIAGNOSIS. Differs from the north Indian race (506), with which Andaman birds were hitherto included, in having the grey of the head and underparts purer, without the pinkish tinge; the green of the upperparts is darker and more blue; tail more blue and darker both above and below; under tail-coverts dingy brown.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	222–260	c. 25–31	25–30	152–177 mm. (Baker)
6 ♂♂	253–265 (av. 257)	—	—	157–169 mm. (av. 161.5)
3 ♀♀	246–250 (av. 248)	—	—	152–158 mm. (av. 155) (Abdulali)

Weight 1 lb. to 1 lb. 12 oz. (454–795 gm.)—Hume.

COLOURS OF BARE PARTS. Irides variable, sometimes pale ruby red; eyelids pale lavender. Bill pale plumbeous, paler on tip and darker on cere and base. Legs and feet dull deep pink, pinkish red or livid purple (Hume).

508a. Andaman Green Imperial Pigeon. *Ducula aenea andamanica* Abdulali

Ducula aenea andamanica Abdulali, 1964, Jour. Bombay nat. Hist. Soc. 61 (2): 414 (Betapur, Middle Andamans)

Not in Baker, FBI

LOCAL NAMES. Not recorded.

SIZE. As 506; length c. 43 cm. (17 in.).

FIELD CHARACTERS. As of the north Indian race 506, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Race peculiar to the Andaman Islands evidently south to the Ten Degree Channel. Common throughout the group. Affects tall evergreen forest.

GENERAL HABITS. As in 506.

FOOD. Items specifically recorded are large yellow flowers and fruits of an unidentified tree, and fruits of *Sideroxylon longepetiolatum*, *Myristica andamanica*, *Calamus pseudorivialis*, and *Ficus infectoria* (Abdulali, JBNHS 61: 525).

116

COLUMBIFORMES

FOOD. Exclusively frugivorous; chiefly wild figs (*Ficus*) and nutmegs (*Myristica*). As in *D. aenea* gape and gullet enormously extensible, ridiculously large nutmegs being swallowed entire, two or three being accommodated in the crop at a time—a seemingly impossible physical feat. The mace is digested, the nut being later voided orally.

VOICE AND CALLS. Rather inadequately described as 'a chuckling *hu-hu-hu*' (Butler). Apparently rather silent, though HA reports an often-repeated *crucroo*, reminiscent of a domestic pigeon's.

BREEDING. Season, reportedly January to March. B. B. Osmaston (JBNHS 18: 201) found some 50 nests in February on South Sentinel I. (c. 1½ km. long, ¾ km. broad) NW. of Little Andaman, each containing a single egg—some fresh some partly incubated. Nest, the usual flimsy stick platform through which the contents visible from below; mostly 7 or 8 metres up in trees. Egg, pure white, fairly glossy, somewhat elongated ellipse. Average size of 28 eggs 45.7 × 30.5 (Osmaston). Share of the sexes in nest-building and incubation, and period of incubation, not recorded.

MUSEUM DIAGNOSIS. Distinctive white and black coloration. No naked skin round eye; lores fully feathered. Tail much shorter than in *Ducula a. nicobarica*. For details of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	c. 218–231	23–26	c. 26–29	c. 125–135 mm. (Baker)
4 ♂♂	233–238 (Nicobars)	(from skull) 26–28	26–27	127–133 mm. (SA)

Weight 2 ♂♂ 465, 510; 1 ♀ 475 gm. (Grubb).

COLOURS OF BARE PARTS. Iris dark brown. Bill leaden blue, the tip darkish horny or dark plumbeous. Legs and feet pale smalt-blue (Davison).

LOCAL NAMES. *Dükür* or *Dükül* (Nepal, Sikkim); *Fomek* (Lepcha); *Ldi bogoma* (Assam); *Hükas* (Paharia).

SIZE. Jungle Crow +; length c. 51 cm. (20 in.).

PIGEONS, DOVES

117

FIELD CHARACTERS. A large greyish brown forest pigeon closely resembling Green Imperial on the wing but readily distinguished from it by larger size and whitish under tail-coverts.

Adult. *Above*, crown and hindneck lilac. Back and scapulars maroon-tinged copper-brown; rump and upper tail-coverts ashy grey. Tail black and brownish grey. *Below*, sides of head grey; throat white; breast and underparts vinous-grey. Under aspect of tail grey with a broad black subterminal band. Under tail-coverts buff. Sexes alike.

Young (immature). Duller than adult: upperparts without the copper-purple tint; upper wing-coverts edged with chestnut.

STATUS, DISTRIBUTION AND HABITAT. Resident; with local movements governed by ripening of wild fruits. Eastern Himalayas from W. Nepal (?), Sikkim, Bhutan and through NEFA; from the terai and foothills to c. 2300 m. Assam hills north and south of Brahmaputra R. Affects tall evergreen forest. Birds from upper Assam (especially the Margherita and Tirap area) tend towards the greyheaded Burmese race *griseicapilla*.

GENERAL HABITS. Similar to *Ducula aenea* (506), q.v. Keeps in small flocks of up to 15 or 20 birds to heavy forest, rarely venturing into scrub jungle as *aenea* often does. Descends to drink, and at salt-licks. Sits high up in lofty trees hidden among the foliage canopy and is mostly seen only when flying high above the tree-tops from one feeding ground to another. Flight swift and powerful but with seemingly leisurely wing-beats — rather crow-like in distant silhouette. Early mornings and again late afternoons the birds sit quietly sunning themselves on bare tree-tops high above the forest, flying off quickly and silently to their roost soon after the shadows have fallen. Bowing display in breeding season consists of the male advancing along a branch towards his mate cooing vigorously *ük-ook . . . ook* with lowered head and inflated throat. Each *ook* uttered with a deep bow, bill pointing groundward. Calls often followed by a spectacular aerial display: the bird launches out from the top of a dead tree, and after a few rapid wing-beats he sweeps vertically upward for c. 6 or 8 metres with closed wings, using only the momentum. At peak of zoom reverses abruptly, bill pointing downward, and nose-dives with wings pulled in at the sides and tail expanded, for about the same distance. At bottom of dive, flattens out and flaps vigorously using the momentum to zoom vertically upward once more and repeat the performance. The manoeuvre repeated two or three times, the bird thereafter re-settling on some nearby dead tree. This switch-back aerial display very similar to Green Imperial's, and reminiscent of both Roller (*Coracias*) and Blackbellied Finch-Lark (*Eremopterix*).

FOOD. Exclusively frugivorous; very largely wild figs (*Ficus*) and nutmegs (*Myristica*), swallowed entire. Gullet and gape enormously extensible, as in 506.

VOICE AND CALLS. Quite distinct from Green Imperial's. A deep, booming far-carrying and rather mournful *ük-ook . . . ook* (or *gü-goo . . . goo*); uttered with tail slightly depressed, rump arched, head bowed, and throat inflated.

BREEDING. Season, March to August; possibly has two broods. *Nest*, the characteristic skimpy platform of interlaced twigs, 5 to 8 metres up in a sapling in forest. *Egg*, normally a singleton — very rarely 2 — white,

PIGEONS, DOVES

119

MUSEUM DIAGNOSIS. Under tail-coverts freckled with dusky; white on chin and throat more restricted than in 510 or 512. See also Key to the Subspecies; for details of plumage Baker, loc. cit.

MEASUREMENTS	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	221-240	29-34	31-34	164-183 mm. (SA, HW)

Tails longer in males.

COLOURS OF BARE PARTS. Iris brown; eyelids magenta. Bill horny brown magenta on cere and base of upper mandible. Legs and feet magenta; claws horny brown.

512. Greyheaded Imperial Pigeon. *Ducula badia griseicapilla* Walden

Ducula griseicapilla Walden, 1875, Ann. and Mag. Nat. Hist. (4), 16: 228
(Karen Hills, between 4000 and 4200 feet)
Baker, FBI No. 1844, Vol. 5: 204

LOCAL NAMES. *Daohukuruma gagao* (Cachar); *Inrukuru gaherba* (Katcha Naga); *Lamkhuru* (Manipur, for wild pigeons generally).

SIZE. As of Nepal Maroonbacked Imperial (510); length c. 51 cm. (20 in.).

FIELD CHARACTERS. A large greyish brown forest pigeon like 510 but with a purer grey head; indistinguishable from it in the field. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Chiefly extralimital, occurring only along the Burma border, in Nagaland, Manipur, and Mizo Hills (?), but the birds here largely intermediate. Affects tall evergreen forest up to c. 2300 m.

Extralimital. Burma and SW. Yunnan to N. Tenasserim, Thailand and all the Indochinese countries.

GENERAL HABITS AND FOOD. As of 510, q.v.

VOICE AND CALLS. As in 510; specifically described in Burma as 'click *ukroom ukroom*, the preliminary click only heard at close range but the other two notes deep and resounding' (Smythies *et al.*, JBNHS 44: 230).

BREEDING. Season, nest and egg (singleton) as in 510.

MUSEUM DIAGNOSIS. Differs from the east Himalayan race *insignis* in having the crown and sides of head pure French-grey, darker than underparts and contrasting strongly with lilac of hindneck. Upper back and smaller wing-coverts more coppery; rump darker and less grey than in *insignis*.

MEASUREMENTS. As in 510 (Baker).

Weight of 2 ♂ 1 lb. 4 oz. (c. 580 gm.) and 1 lb. 7 oz. (c. 665 gm.) respectively; ♀ ♀ weigh somewhat less (Davison).

COLOURS OF BARE PARTS. Iris whitish. Bill cerise, tip plumbeous-brown. Feet dull cherry-red' (SDR).

Genus COLUMBA

Columba Linnaeus, 1758, Syst. Nat., ed. 10, 1: 162. Type, by subsequent designation, *Columba oenas* Linnaeus (Vigors, 1825).

Alloceus Blyth, 1842, Jour. Asiat. Soc. Bengal 11: 461. Type, by monotypy, *Columba puniceus* Blyth.

118

COLUMBIFORMES

elliptical, fairly glossy. Average size of 22 eggs 46.2 × 33.5 mm. (Baker). Both sexes take part in nest-building and incubation; incubation period undetermined. Birds sit very close, usually leaving nest only when climber within a metre or so.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.; for the subspecies, Key.

Fresh skins are so different in tone from old specimens in collections that at first glance it is difficult to assign them to the same race. The oxidation process inherent in 'foxing' has turned the upperparts of old skins into brown and copper-coloured and taken away the greyish bloom of the fresh skin.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	228-259	c. 25-27	c. 25-32 mm.	— (Baker)
		(from skull)		
2 ♀ ♀	242-245	30-35	29-32	176-187 mm. (SA)

COLOURS OF BARE PARTS. Iris pale- to bluish grey; orbital skin purple-grey, purer grey next the eye. Bill pale brown, white at tip; cere and base of upper mandible fleshy purple or dull carmine. Legs and feet dull cherry-red; claws pale brown.

511. Jerdon's or Southern Maroonbacked Imperial Pigeon. *Ducula badia cuprea* (Jerdon)

Carpophaga cuprea Jerdon, 1840, Madras Jour. Lit. Sci. 12: 12 (Wynaad)
Baker, FBI No. 1845, Vol. 5: 205

LOCAL NAME. *Manti prāru* (Malayalam).

SIZE. Crown ±; length c. 43 cm. (17 in.).

FIELD CHARACTERS. A large forest pigeon, dull olive-brown or liver-brown above with pale greyish lilac head, neck and underparts. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Resident, with seasonal local and altitudinal movements depending on wild fruit ripening. The Western Ghats and associated hills (Nilgiri, Palni, etc.) in Kerala, western Mysore (Malnaad) north to about Belgaum and Goa (c. lat. 16°N.). Affects evergreen forest up to c. 2000 metres. Alleged occurrence in Ceylon not confirmed.

One of the peculiar discontinuously distributed Indo-Malayan forms separated from its nearest east-Himalayan relative by at least 1800 km. of ecologically unsuited country.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in the Nepal race (510), q.v.

BREEDING. Season, chiefly January to May. *Nest*, the typical flimsy pigeon structure — a skimpy platform of interlaced twigs through which the contents usually visible from below. Built in small trees, tangles of creepers draping them, or occasionally on the branches of bigger trees, between c. 5 and 8 metres up. *Egg*, normally a singleton, white, elliptical, fairly glossed. Average size of 12 eggs 44.4 × 34.6 mm. (Baker). Incubation by both sexes; period undetermined.

COLUMBIFORMES

Ianthoenas Reichenbach, 1852, Nat. Syst. Vög.: 25. Type, by original designation, *Columba ianthina* Temminck & Schlegel.

Dendrocygna Blyth, 1843, Jour. Asiat. Soc. Bengal 12: 937. Type, by monotypy, *Columba hodgsonii* Vigors.

Tail short or of moderate length, square or very slightly rounded. Wings long and pointed reaching to, or almost to, the end of tail in most species. Tarsus bare, shorter than middle toe with claw, the upper part overhung by feathers. Feet without broad padded soles as in fruit pigeons; well adapted for walking. Nostrils narrow and obliquely set in the swollen cere.

(Himalayas, type probably from Nepal).
Baker, FBI No. 1858, Vol. 5: 224
Plate 48, fig. 5

LOCAL NAMES. *Bājīl* (Chamba); *Chat ketūr* (Kashmir); *Lho pen rentiep* (Lepcha); *Bya dān* (Bhutes).

PIGEONS, DOVES

121

SIZE. Pigeon; length c. 34 cm. (13½ in.).

FIELD CHARACTERS. A particoloured brown and white Himalayan pigeon reminiscent of the domestic bird. In overhead flight the white body and blackish head are pointers; when flying below observer's level the blackish head, brown back, white rump-patch, grey wings with 3 dark bars, and blackish tail with a narrow white subterminal band, are diagnostic features. Sexes alike.

Young (immature). Feathers of upperparts and wings with narrow pale buff margins. White of underparts sullied with buff.

STATUS, DISTRIBUTION and HABITAT. Resident in the Himalayas chiefly between 3000 and 5000 metres; descending lower in winter to c. 1500 m. (occasionally to c. 750 m.). From the Afghan frontier in NW. Pakistan

Columba leuconota

■ Distributional range 1 *C. l. leuconota* (513). 2 *C. l. gradaria* (514).

eastward through Kashmir, Garhwal, Kumaon and Nepal to eastern Sikkim, where intergrading with *gradaria* (514) takes place. Does not extend far north into the desolate Tibetan Plateau. Affects rock cliffs and steep gorges in the alpine zone and above the snow line.

Extralimital. The Alai Mountains and the Pamirs in SW. Turkestan.

GENERAL HABITS. Similar to those of the wild Blue Rock Pigeon (517), living and roosting in colonies on cliffs; sometimes also perching on adjacent trees. Keeps in pairs and small parties in summer, feeding on open boulder scree and grassy slopes, or on the edge of melting snow patches. Gathers in large restless flocks in winter, often of 150 birds or more, flying about incessantly or gleaning in freshly sown wheat and barley fields around mountain villages. Whilst feeding the birds run about briskly like sheep at grass, often forming a close-packed jostling phalanx, each bird eager to be

PIGEONS, DOVES

Extralimital. Mountains of E. Tibet and W. China from the eastern Nan Shans south through Kansu and Szechuan to Yunnan and extreme NW. Burma (Peters).

GENERAL HABITS, FOOD, VOICE and CALLS. As in 513, q.v.

BREEDING. As in 513.

MUSEUM DIAGNOSIS. Birds from the eastern end of its range (Kansu and Szechuan) are somewhat larger and paler, with the head more slaty grey less blackish. In freshly moulted plumage the underparts are washed with pale greyish. Abdomen pale grey, darkening on under tail-coverts.

MEASUREMENTS

17 ♂♂ (from Kansu and Szechuan) give Wing 241-260 (av. 248) mm. against 20 ♂♂ from the western end of the range of nominate *leuconota* (Punjab Himalayas) 235-248 (av. 240.5) mm. — Vaurie, 1965.

COLOURS OF BARE PARTS. As in 513.

515. Turkestan Hill Pigeon. *Columba rupestris turkestanica* Buturlin

Columba rupestris turkestanica Buturlin, 1908, Orn. Monatsb. 16: 45 (Altai). New name for *Columba rupestris pallida* Rothschild & Hartert, preoccupied Baker, FBI No. 1857, Vol. 5: 222

Plate 48, fig. 4

LOCAL NAMES. *Taica kăblâr* (Turki); *Angoa*, *Ankhu*, *Oron* (Tibetan).

SIZE. Blue Rock Pigeon; length c. 33 cm. (13 in.).

FIELD CHARACTERS. A high-altitude Himalayan pigeon, very similar to the familiar Blue Rock (517) but readily distinguished from it by much paler upper plumage and whitish underparts; in flight also by a broad white band across middle of blackish tail — a pattern similar to snow pigeon's. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Resident in the Himalayas usually above the range of *livia*, in Gilgit, Chitral, Ladakh, Kashmir, Lahul, Spiti and through Garhwal eastward to Sikkim (not recorded in Nepal); between c. 3000 and 5500 m. in summer, to lower elevations in winter, occasionally down to c. 1500 m. Affects rocky cliffs and gorges and open rugged country, chiefly the northern slopes of the Himalayas in Tibetan Plateau facies.

Extralimital. Russian Altai, south through Turkestan and western Tibet.

GENERAL HABITS. Lives in colonies on crags and precipices at high altitudes, usually within commuting distance from upland villages where it resorts to feed in the surrounding cultivation. Has been recorded making daily visits to Everest mountaineers' camps up to c. 6100 metres. Usually tame and unafraid of man, moving about and picking grain and dung amongst the muleteers' bivouacs. Flocks commonly met with also along beaten mule tracks and trade routes picking up grains spilt during transport; visits high mountain passes to glean the votive grain scattered by devout pilgrims and travellers. Unlike snow pigeon, also frequents deserted crumbling dwellings where available. Feeds chiefly in the morning and afternoon, sitting about on cliffs and ledges during the day. Bowing display superficially similar to Blue Rock Pigeon's, but not specifically studied.

COLUMBIFORMES

122

the first to investigate new ground. Coloration remarkably obliterative on gravelly soil even at close range, particularly amongst piebald patches of melting snow. In summer reported to feed higher up in the evenings than in the mornings on patches of bare ground whence the snow has melted during the day. Flight, typical of pigeons, strong and direct, with rapid wing-beats. Flapping flight rather reminiscent of Cotton Teal; when sailing gracefully round contours of cliffs, of Ashy Swallow-Shrike.

FOOD. Chiefly weed seeds (once 16 gm. in a crammed crop), barley and other cultivated grain; bulbils (of *Polygonum* etc.). Meinertzhagen found crops stuffed with green food such as crocus bulbs and other small roots, small hard seeds, and a large quantity of quartzite grit.

VOICE and CALLS. Described as 'a repeated croak, not unlike a hiccup', apparently very different from the normal coo of a pigeon. 'On taking flight and alighting a prolonged, high-pitched and tremulous coo reminiscent of the note of the common myna when taking wing' (W. H. Matthews).

BREEDING. Season, principally May to July. Nest, the characteristic skimpy platform of a few twigs, or sometimes a little matted straw and a few feathers. Placed on inaccessible ledges of cliffs and in rock caves and fissures, often in large colonies. Eggs, 2, white, smooth-textured. Average size of 40 eggs 40.3 × 29.1 mm. (Baker). Share of the sexes in the domestic chores, and period of incubation, undetermined.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	240-258	c. 24-25	c. 31-35	122-137 mm. (SA)

Weight 3 ♂♂ 277-300; 3 ♀♀ 255-307 gm. (GD).

COLOURS OF BARE PARTS. Iris lemon-yellow. Bill horny brown; cere magenta-brown. Legs and feet reddish pink; claws horny brown.

514. East Himalayan Snow Pigeon. *Columba leuconota gradaria* Hartert

Columba leuconota gradaria Hartert, 1916, Nov. Zool. 23: 85 (Sungpan, Szechuan) Baker, FBI No. 1859, Vol. 5: 225

LOCAL NAMES. *Lho phu rentiep* (Lepcha); *Dya don* (Bhutea).

SIZE. Pigeon; length c. 34 cm. (13½ in.).

FIELD CHARACTERS. A particoloured brown and white Himalayan high-altitude pigeon, indistinguishable in the field from 513. See Key and Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident in the Himalayas from extreme eastern Sikkim eastward through Bhutan and NEFA, between c. 3000 and 4500 m. in summer, descending to c. 1500 or lower in hard winters. Does not extend far north into the Tibetan Plateau. Affects rocky cliffs and gorges in the alpine zone and above the snow line.

This eastern population differs from the west Himalayan one clinally. Birds from eastern Sikkim (and Chumbi Valley, Tibet) are intermediate, showing a gradual intergrading between the two forms.

COLUMBIFORMES

124

Columba rupestris

■ Distributional range 1 *C. r. rupestris* (RE). 2 *C. r. turkestanica*.

FOOD. Chiefly green shoots of crops, grain of oats and barley, and weed seeds. A quantity of quartzite grit present in stomachs.

VOICE and CALLS. A high-pitched, quick-repeated *gūt-gūt-gūt-gūt* with a sort of 'jeering' intonation reminiscent of *Ducula aenea*.

BREEDING. Season, principally April to June/July; possibly double-brooded. Nest, the typical scanty pigeon platform of a few bents often matted with excreta, placed in a hole or fissure in a cliff face — sometimes in the crumbling piled stone wall of a deserted dwelling; usually several nests near one another, in a colony. Eggs, 2, white, smooth-textured. Average size of 50 eggs 37.0 × 27.5 mm. (Baker). Share of the sexes in the domestic chores and incubation period not recorded.

MUSEUM DIAGNOSIS. See Key. Wing very pointed: 1st primary (h.a.) equal to 2nd or longer. For details of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂♂	216-243	15-17	c. 25-28	c. 118-130 mm. (Baker)

Wing 5 ♂♂ 230-240 (av. 233.4); 6 ♀♀ 219-228 (av. 223.8) mm. — Strassmann

COLOURS OF BARE PARTS. Iris deep orange. Bill slaty black, tinged on cere and gape with plumbeous or flesh colour. Legs and feet coral-red; claws horny.

516. Blue Rock Pigeon. *Columba livia neglecta* Hume

Columba neglecta Hume, 1873, in Henderson & Hume's Lahore to Yarkand: 272 (Ladak)

Baker, FBI No. 1855, Vol. 5: 220

LOCAL NAMES. *Kābūtār* (Hindi); *Kentisiam* (Pushlu); *Kāpūth*, *Chāhi* (Baluchi); *Kāfīār* (Persian); *Wān kotār* (Kashmir).

SIZE. As of 517; length c. 33 cm. (13 in.).

FIELD CHARACTERS. As of 517; indistinguishable from it in the field. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident, with seasonal movements — chiefly altitudinal — in W. Pakistan (Gilgit, Chitral, NW. frontier districts, Baluchistan, Sind) and NW. India (Ladakh, Kashmir, Punjab, Himachal Pradesh) from plains level to c. 3300 m. up in the Himalayas. Possibly in a less pure and semi-feral form over the greater part of the Peninsula.¹ Affects rocky gorges and precipices in the Himalayas in the neighbourhood of upland cultivation; also ruins and ancient forts about towns and villages lower down and in the plains.

Extralimital. *Transcaspiia and Turkestan, south to S. Persia* (Peters).

GENERAL HABITS, FOOD, VOICE and CALLS. As in 517, q.v.

BREEDING. Season, principally April to August but also at other times; except for the winter months at the higher altitudes. *Nest*, the typical scanty pad of a few twigs or bents often befouled and matted by the birds' droppings; placed in a hole or crevice of rock on inaccessible scarps at high elevations; also in deserted ruins and crumbling forts lower down. *Eggs*, 2, white, smooth-textured. Average size of 48 eggs 38.5 × 28.7 mm. (Baker). Breeding biology as in 517.

MUSEUM DIAGNOSIS. Paler and somewhat larger than *intermedia*, with the rump varying from pure white to pale blue-grey. But the differences seem clinal in character, and no boundary between NW. Indian and peninsular birds can be fixed.

MEASUREMENTS

Wing 10 ♂♂ 230-242 (av. 236); 10 ♀♀ 218-241 (av. 228.1) mm. (Vaurie, 1965).

COLOURS OF BARE PARTS. As in 517.

SIZE. Length c. 33 cm. (13 in.).

FIELD CHARACTERS. A familiar bluish grey pigeon with glistening metallic green, purple, and magenta sheen on upper breast and round the neck, and two dark bars on the wings. Sexes alike.

¹ See Salim Ali, 1954, JBNHS 52: 428-9.

PIGEONS, DOVES

127

in dwelling-houses and mosques, and similar places form favourite sites. Holes in trunks of palms and other large trees are frequently appropriated. *Eggs*, 2, white, smooth-textured, elliptical. Average size of 100 eggs 36.9 × 27.8 mm. (Baker). Both sexes share nest-building, incubation, and tending the young. Incubation period c. 16 days. Squabs fed on regurgitated pap of semi-digested grain mixed with a secretion of the crop ('pigeon's milk').

MUSEUM DIAGNOSIS. Subspecies *intermedia* distinguished by upper back, lower back, and rump being concolorous dark bluish grey; in *neglecta* (516) lower back and rump contrastingly white or greyish white. For details of plumage see Baker, loc. cit.

MEASUREMENTS

Wing	Bill (from skull)	Tarsus	Tail
14 ♂♂ (Peninsula and Ceylon) 213-232	24-26	30-33 (1 ♀ 25)	97-115 mm. (SA, HW)

Wing ♂♂ 210-238; ♀♀ 202-232 mm. (Baker).

COLOURS OF BARE PARTS. Iris orange. Bill brownish black; cere powdery greyish white. Legs and feet magenta; claws brownish black.

MISCELLANEOUS. In many parts of India and Pakistan pigeons enjoy a certain amount of protection based on religious sentiment and are passively, if not cheerfully, tolerated in mosques and temples despite the filthy mess they make on the floor.

There are stories that have gained wide popular credence about the wild pigeons inhabiting the Vengurla Rocks off the Ratnagiri coast, and the gigantic rock scarps flanking Gersoppa or Jog Falls in Mysore. It is believed that the birds lay up — or at least used to lay up — during the dry season a regular granary in caves and hollows for monsoon consumption. In the case of Gersoppa the quantity of hoarded paddy was so large that the right of collecting the grain used to be auctioned by the Bombay Government, a hundred years or so ago, for Rs 500 annually. It is alleged that 20 candies (c. 70 quintals) or more were plundered at a time by a man lowered in a basket. Since a misadventure which terminated the career of the last intrepid exploiter in action, no one has evidently mustered enough nerve to tap this store. As the governmental records have all been destroyed after superannuation the truth about the alleged auction fee and other relevant details cannot now be traced. Believers offer no explanation of how the pigeons transported such vast quantities of paddy to Gersoppa over the many miles from the nearest paddy cultivation, or over the 15 km. or so of sea that separates Vengurla Rocks from the Konkan coast! However, it would be interesting to learn the factual bases of these two quite independent legends¹. (For particulars see Vidal, G. W., 1881, SF 9: 74; Salim Ali, 1943, JBNHS 44: 24-5.)

COLUMBIFORMES

126

STATUS, DISTRIBUTION and HABITAT. Resident and locally abundant throughout the Indian Union, Nepal, Bhutan, E. Pakistan, Ceylon and Laccadive Islands; plains and hills — up to at least c. 3000 m. in the Himalayas, where it is a seasonal altitudinal migrant. Was introduced into Car Nicobar Island in c. 1898 but has apparently failed to become established (Abdulali, 1964, JBNHS 61: 526). Affects rocky cliffs and gorges in the hills, old ruins, ancient forts on the countryside, factory and warehouse sheds, residential and public buildings, temples, railway stations, etc. in populous cities.

Extralimital. Burma, Thailand.

GENERAL HABITS. In the wild state lives in colonies, roosting on ledges, and in fissures and holes in rock scarps, crumbling hill forts, ancient ruins, or down the shafts of old wells. Some colonies roost in palm trees in wild date groves, and in groves of large trees near villages. From here the birds flight regularly back and forth, often considerable distances, in small parties or large flocks of several hundred strong to feed in the mornings and afternoons, gleaning spilled grain in stubble fields and around ryots' threshing floors. They cause considerable local damage by digging out newly sown maize, pulse and other cereals, and also to groundnut crops. Flight swift and powerful with rapid wing-beats and tail fairly fanned out; often followed by a graceful sweep round contours of cliffs and upward glide before alighting. Short flights from ledge to ledge on nesting cliffs by deliberate wide deep strokes ('delayed action') and loud clapping together of wings above the back — a form of display during the breeding season. In urban localities the Blue Rock has degenerated into a semi-feral commensal of man, living in and about buildings in towns and cities, regularly fed at appointed places by pious citizens, and leading a pampered life of indolent ease. The birds become completely inured to the din and bustle of the most congested bazaars and factories, roosting and nesting within the buildings regardless of the inmates, and making an unmitigated nuisance of themselves by the filthy mess they create. They interbreed freely with domesticated varieties, producing a chaotic mixture of races.

FOOD. Grains of maize, jowar, and other cereals, moong dāl and other pulses; groundnuts, weed seeds, small tubers and green shoots of ground crops. A quantity of grit usually present in stomachs.

VOICE and CALLS. A deep *goolr-goo*, *goolr-goo*, etc. uttered by the male with head bowed and throat puffed out while he turns round and round on his own axis in courtship or aggressive display. A deep, nasal *goo*, *goo*, *goo* by an unaccompanied bird — apparently both sexes — at nest site; a squeaky squealing by squab begging for food.

BREEDING. Season not well defined, practically all year; mainly between May and July in the higher Himalayas, varying locally elsewhere. In heavy-rainfall areas activities slacken between July and September. Double (or multiple ?) brooded. *Nest*, the usual skimpy pad of bents, rubbish, and a few feathers, etc. often befouled and matted with the bird's droppings. Placed on sheltered ledges and in holes and fissures in rock scarps and crumbling ramparts of hill forts; often in large colonies, the nests sometimes huddled close together. In urban locations holes and niches in the sides of masonry and kutchra wells, rafters in factory and warehouse sheds, cornices

COLUMBIFORMES

128

518. Eastern Stock Pigeon. *Columba eversmanni* Bonaparte

Columba eversmanni Bonaparte, 1856, Compt. Rend. Acad. Sci. Paris 43: 838

(Western and central Asia)

Baker, FBI No. 1860, Vol. 5: 226

Plate 48, fig. 3

LOCAL NAMES. *Pāhāri kābūtār* (Hindi); *Bān pārāwā*, *Bāgar* (Bihar); *Kāpūth*, *Chari kāpūth* (Baluchi); *Kāfīār* (all pigeons, Persian).

SIZE. Pigeon —; length c. 30 cm. (12 in.).

FIELD CHARACTERS. A smaller and paler edition of the Blue Rock Pigeon, easily recognized on the ground and in flight by the dark grey rump contrasting with white lower back. In fading light flight silhouette confusingly like Ring Dove (534) but the comparatively shorter tail of the pigeon usually decisive.

Adult, overall ashy grey. Crown, hindneck and breast tinged with vinous or lilac; sides of lower neck glossed metallic green and lilac showing up as a distinct patch of glossy purple-red on either side. Three interrupted black bars on wing. Lower back pure white; rump, upper tail-coverts, and most of tail leaden grey; terminal third of tail blackish with a paler grey band across the outer feathers. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Winter visitor and/or passage migrant, chiefly W. Pakistan (NW. frontier districts, Baluchistan, Sind). Less commonly also NW. India — recorded in Jammu and Kashmir,

Columba eversmanni

■ Breeding range □ Winter

Punjab (Ludhiana and Ambala dists.); Uttar Pradesh (Lucknow and Gorakhpur dists.), and as far east as Bihar (Darbhanga dist.). Affects groves of trees amidst open cultivated country.

PIGEONS, DOVES

129

MIGRATION. 'Migrates in small flocks through Kohat in the latter half of April; probably also through the Kurram Valley' (Whitehead, 1911, JBNHS 20: 966-7).

EXTRALIMITAL. Turkestan from the Aral Sea to N. Afghanistan and east to Zaisan-nor. For details of range see Vaurie, 1955: 542.

GENERAL HABITS. Similar to those of the Blue Rock Pigeon (517), q.v. Keeps in small parties or flocks, sometimes of a hundred or more. Roosts in poplar, mango or babool groves, feeding in the surrounding fields in the mornings and afternoons, often in company with Blue Rocks, resting in the trees during mid-day. Flight fast and direct but interrupted by lightning twists and turns when once thoroughly disturbed, the birds then affording a variety of difficult shots and excellent sport with the gun.

FOOD. Ripening mulberries plucked from the trees. Maize and other cereals dug up in freshly sown fields or gleaned in stubbles after harvest.

VOICE AND CALLS. Not recorded in India.

BREEDING. Extralimital. Colonial. Season, May-June. Nest, the characteristic flimsy twig platform placed high up in a poplar tree, in a hollow in a trunk, or hole in an earthen cliff. Eggs, 2, white.

MUSEUM DIAGNOSIS. See Key; for details of plumage Baker, loc. cit.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂ ♀	200-208 (once 210)	c. 16-19 (from feathers)	c. 26-28	96-105 mm. (Hartert)
Wing 7 ♂♂ (Afghanistan)	197-205; 1 ♀ 194 mm.		Weight 183-234 gm. (Paludan).	
COLOURS OF BARE PARTS. Iris light yellow to golden brown; bare skin around eyes pale yellow. Bill greenish, slaty at base brownish at tip. Legs and feet pale flesh; claws horny brown.				

519. Eastern Wood Pigeon or Cushat. *Columba palumbus casiotis* (Bonaparte)

Palumbus casiotis Bonaparte, 1854, Compt. Rend. Acad. Sci. Paris 39: 1103 (Chinese Tartary)

Baker, FBI No. 1861, Vol. 5: 227
Plate 48, fig. 6]

LOCAL NAMES. *Dahnud* (Chamba); *Kūkil* (Kashmir); *Sitera* (Punjab).

SIZE. Pigeon +; length c. 43 cm. (c. 17 in.).

FIELD CHARACTERS. A large, stout grey and brown pigeon distinguished by a broken buff collar at sides of hindneck, and a broad whitish band across wing very prominent in flight.

ADULT. Above, head and upper neck all round dark ashy grey with narrow bare red ring round eye. Sides of lower neck glossed metallic green and purplish red near the shoulders; a conspicuous buff spot (like broken half collar) on either side of neck near body. Mantle brownish grey; a broad whitish longitudinal band on wing. Lower back, rump, and upper tail-coverts dark ashy grey; tail above mostly blackish. Below, ashy grey, tinged with lilac or vinous on breast. Tail underneath black with a broad whitish grey band across the middle. Sexes alike.

PIGEONS, DOVES

131

Nuptial display rather similar to that of Ring Dove (534), rising a few metres steeply from a branch with a couple of loud claps of the wings and volplaning down to another perch some distance away.

FOOD. Cereals, gleaned on the ground or pecked out of freshly sown fields; buds, acorns, mulberry, *bēr* (*Zizyphus*) and other berries plucked from trees and bushes.

VOICE AND CALLS. A deep muffled cooing of five notes *kookoo-koo* . . . *kookoo* (accent on 2nd syllable) with slight variations, repeated two or three times.

BREEDING. From c. 700 m. (Salt Range) to c. 2500 m. (N. Baluchistan, Gilgit). Season, April to August; chiefly June and July at the higher altitudes. Nest, a sketchy pad of interlaced twigs placed 4 to 6 m. or so up in a juniper, pine, oak, or other tree in forest. Eggs, 2, pure white, fairly glossy. Average size of 50 eggs 37.0 × 27.5 mm. (Baker). Incubation and other details not recorded in India.

MUSEUM DIAGNOSIS. Neck and tail longer than in Blue Rock Pigeon. Wing more rounded: 1st primary (as.) more or less equal to 4th. No dark bars on wing. For details of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂ ♀	243-263	(from feathers) c. 17-18	c. 24-27	139-153 mm. (Baker)

COLOURS OF BARE PARTS. Iris pale yellow; circumorbital skin carmine-red. Bill rather variable: orange-red at base, pinkish white in centre, orange at tip; cere whitish. Legs and feet coral-red.

520. Speckled Wood Pigeon. *Columba hodgsonii* Vigors

Columba Hodgsonii Vigors, 1832, Proc. Zool. Soc. London, pt. 2: 16 (Nepal)
Baker, FBI No. 1867, Vol. 5: 234
Plate 48, fig. 14

LOCAL NAMES. *Hagrani daohukuruma* (Cachar); *Pāhāri pagooma* (Assam); *Bhākalā* (Garhwal).

SIZE. Pigeon +; length c. 38 cm. (c. 15 in.).

FIELD CHARACTERS. A dark arboreal Himalayan pigeon.

Male (adult). Above, head and neck grey, the latter speckled with blackish behind. Upper back and wing-shoulders (coverts) claret-maroon, the latter speckled with white. Rest of upperparts dark brown and dark grey; tail blackish brown. Below, upper breast grey, speckled with blackish grey and claret, changing to uniform claret on lower breast and passing into deep slaty grey on abdomen and under tail-coverts. The bright yellow claws contrasting with the dull green feet are an arresting feature through binoculars.

Female has grey of head brownish, and red of back and breast duller and browner.

STATUS, DISTRIBUTION AND HABITAT. Resident, with local altitudinal and spatial movements dependent on food supply. The Himalayas from Gilgit

130

COLUMBIFORMES

STATUS, DISTRIBUTION AND HABITAT. Resident and rather erratic wanderer and altitudinal migrant. W. Pakistan (Chitral, Gilgit, NW. frontier districts, Salt Range, Baluchistan, Sind ?); and NW. India (Jammu and Kashmir). In summer chiefly between c. 1500 and 3000 m.; in winter at lower altitudes. Affects wooded hillsides, valleys, and nullahs with firs, oaks

Columba palumbus

1 *C. p. palumbus* (RE).
2 *C. p. cariotis*. 3 *C. p. extelsa* (RE).

and junipers, etc. Not reported within recent years in the Himalayas east of Kashmir—in Garhwal, Kumaon, where in the 1830s Hume found it about Simla, Mussooree and Almora between November and April. There is an old specimen from Nepal where a large flock was recently observed by R. L. Fleming in Kathmandu Valley at c. 2300 m. in February (JBNHS 65(2): 327). Reported occurring in winter in vast flocks ('of thousands', '17 killed in a single shot') even until 1952 in parts of Punjab (Man Mohan Singh) and Doon Valley, Kumaon (S. M. Osman), now almost completely deserted. Cause needs investigation.

EXTRALIMITAL. Turkestan and Zaisan, south to eastern Persia (Peters).

GENERAL HABITS. Locally abundant. Keeps in small parties and large flocks in non-breeding season, sometimes of 50 or more birds. Moves about a great deal depending on food conditions, normally descending to the lower limit of its range (800 m. or so) in November/December and ascending to c. 3000 or 3500 m. in March/April to breed, commuting back and forth daily in quest of food over a wide range of altitudes. Feeds on the ground in paddy stubbles etc. as well as in trees and shrubbery. Flight fast and direct, with rapid steady wing-strokes, accompanied by a loud initial clatter when suddenly flushed from tree or ground. Congregates in large numbers to roost in oak woods etc.

COLUMBIFORMES

132

and Kashmir eastward through Garhwal, Kumaon, Nepal, Sikkim, Bhutan and NEFA; Nagaland, Manipur, Mizo. E. Pakistan (?). Affects tall evergreen and semi-evergreen hill forest of oak, rhododendron, etc., between c. 1800 and 4000 metres.

EXTRALIMITAL. Burma and western China (S. Kansu, W. Szechuan, W. Yunnan)—Peters.

GENERAL HABITS. Chiefly arboreal and frugivorous, but also glean weed seeds and cereal grain in harvested stubbles. Keeps in twos and threes and small flocks of 6 to 10, wandering about the wooded hillsides and valleys in search of fruits and berries. The birds clamber about among the foliage while feeding, and have a habit of 'freezing' on alarm, as on an observer's approach, in whatever position they happen to be, even hanging upside down! Flies with steady purposeful wing-strokes high above the forest when travelling from one feeding ground to another.

FOOD. Acorns, drupes, and berries. Blue-black plum-like fruits of *Prinsepia utilis* favoured in Garhwal (local name of the fruit *Bhākalā*, same as of the bird). Cereal grains, weed seeds.

VOICE AND CALLS. A very deep *whack-whr-o-o* . . . *whroo*.

BREEDING. Season, at c. 1800 to 3300 metres altitude, chiefly May-June. Nest, a sketchy platform of interlaced twigs, placed in a leafy branch c. 8 m. up in an oak or similar tree in forest or wooded nullah. Egg apparently only a singleton, white, smooth-textured. Average size of 8 eggs 39.3 × 30.1 mm. (Baker). Courtship display, incubation period, etc. not recorded.

MUSEUM DIAGNOSIS. Distinguished from all other pigeons by the tapering elongated feathers of the neck. No metallic gloss on any part of the plumage; for details of latter see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂ ♀	228-244	(from feathers) c. 16-18	c. 24-26	140-153 mm. (Baker)

Wing 4 ♂♂ (Sikkim) 218-232 mm. (av. 227.7); 4 ♀♀ 221-233 mm. (av. 225.4) — Stresemann.

COLOURS OF BARE PARTS. Iris greyish white; ocular skin grey. Bill purple at base; black distally. Legs and feet brownish yellow to dull green; claws bright yellow.

521. Nilgiri Wood Pigeon. *Columba elphinstonii* (Sykes)

Ptilinopus Elphinstonii Sykes, 1833 (1832), Proc. Zool. Soc. London, pt. 2: 149 (The Ghats of Dukhun)

Baker, FBI No. 1862, Vol. 5: 228
Plate 48, fig. 7

LOCAL NAME. *Marapāw* (Malayalam).

SIZE. Pigeon +; length c. 42 cm. (16½ in.).

FIELD CHARACTERS. A large dark forest-haunting fruit pigeon with grey head and a conspicuous black-and-white 'cheesboard' of white-tipped stiff

PIGEONS, DOVES

133

Above, reddish brown with a glistening metallic green-and-purple sheen on upper back. *Below*, chin and throat whitish; rest of underparts grey with a lilac tinge on abdomen. Under tail-coverts and underwing lining slaty. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Resident, but moving about a great deal consequent upon fruit ripening: the Sahyadri or Western Ghats complex from Kerala northward to c. 19°N. lat. (a little beyond Bombay), including the Anaimalais, Nilgiris, Palnis, and hills of western Mysore (Malnaad). Affects moist evergreen forest from the foothills up to the highest sholas at c. 2000 m. In Kerala cardamom sholas with their tall shade trees constitute a favourite habitat.

GENERAL HABITS. Frugivorous and arboreal, but frequently descending to the mulchy forest floor to feed on fallen berries and snails. Keeps singly, or in pairs and small parties. Wanders about a good deal: a shola full of them one week may not contain a single bird the next when the particular attraction — some special berry — is over. Rests sitting quietly up in densely foliated trees. Numbers reported roosting at night on the roof trusses of an old derelict grass hut high up in the Anaimalai Hills, but this unusual. Flies at speed, twisting and turning through the dense tree-trunks and branches in forest with remarkable agility, and offering a number of difficult snap shots to the sportsman.

FOOD. Various fruits, berries, and buds; 'small snails' (Jerdon).

VOICE and CALLS. A langur monkey-like *who*, somewhat undertone, followed by three or four quick-repeated deep owl-like, almost eerie, notes *who-who-who* or *who-who-who-who*.

BREEDING. Season, March to July, principally April to June. *Nest*, the typical sketchy pigeon platform of twigs, placed in a moderate-sized tree in a shola, normally above c. 1000 metres elevation. *Egg*, a singleton, pure white. Average size of 9 eggs 38.4 × 28.8 mm. (Baker). Other particulars of breeding biology unrecorded.

MUSEUM DIAGNOSIS. See Key; for details of plumage Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	204-224	c. 17-18	c. 25-26	152-178 mm. (Baker)

5 ♂ ♀ (from Kerala and Mysore) wing 199-205; bill (from skull) 27-28 mm. (SA). Weight 1 ♂ 379 gm. (SA).

COLOURS OF BARE PARTS. Iris bright khaki or greyish brown. Bill, basal half including cere magenta; distal half old ivory white; mouth greyish pink. Legs and feet magenta; claws old ivory.

MISCELLANEOUS. Advice of one epicure: 'Do not put in a pie but serve on toast!'

PIGEONS, DOVES

135

buff collar, and all round lower neck blackish with iridescent sheen of lilac and green. Tail blackish brown. *Below*, chin white changing to buff on throat and passing into the glossy buff collar. Breast metallic-glossed dark slaty blue passing into pale cinnamon or brownish buff on abdomen and vent. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Resident, but like other fruit pigeons subject to considerable wandering dependent on fruit supply; from west-central Nepal through Sikkim, Bhutan, NEFA, Nagaland, Manipur (?), Mizo (?). Normally between c. 1200 and 3200 m., but recorded locally in Bengal duars and NEFA foothills (Charduar, Gorumara) as low as 100-150 m. in both winter and summer, so possibly resident. Altitudinal movements unclear. Affects dense mixed deciduous and evergreen forest of oak, chestnut, and rhododendron, etc.

Extralimital. NE. Burma, Arakan, N. Thailand, Taiwan.

GENERAL HABITS. Very little specifically known. Largely frugivorous and arboreal. Keeps singly, or in pairs or small flocks of 10 to 30 birds. Shy and difficult to observe as it usually sits quietly high up in a tree concealed by the foliage, launching out on the approach of an observer with a muffled clatter of wings, flying fast and silently and vanishing among the trees. Normally very silent and thus doubtless often overlooked.

FOOD. Various drupes and berries, acorns, grain and seeds; 'tiny snails, wild cardamom pods' (Baker).

VOICE and CALLS. Seldom heard, and needs proper description. Described as a deep, sonorous *coo* very like that of the English Wood Pigeon, but perhaps deeper still, and more abrupt and less soft (Baker, 1913: 175).

BREEDING. Little known. Season (Darjeeling dist.) evidently May to August. *Nest*, the usual flimsy twig platform fairly low down in a small tree in forest. *Egg*, singleton, white, c. 38 × 28 mm. No other information.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	194-216	16-17	c. 22-25	120-130 mm. (Baker)

COLOURS OF BARE PARTS. Iris white, greyish white, or pale yellow; ocular skin grey. Bill purplish at base, dull grey-green distally. Legs and feet fleshy purple to coral-red, soles paler; claws horny brown.

524. Purple Wood Pigeon. *Columba punicea* Blyth

Columba (Alucoemus) puniceus 'Tickell' = Blyth, 1842, Jour. Asiat. Soc. Bengal 11(1): 461 (Chyebassa [Chaibasa, Bihar])
Baker, FBI No. 1865, Vol. 5: 232
Plate 48, fig. 11

LOCAL NAMES. *Lili pegoona* (Assam); *Dashukuruma kero goftu* (Cachari).

SIZE. Pigeon +; length c. 36 cm. (14 in.).

134

COLUMBIFORMES

522. Ceylon Wood Pigeon. *Columba torringtoni* Bonaparte

Columba torringtoni 'Layard' = Bonaparte, 1854, Compt. Rend. Acad. Sci. Paris 39: 1103 (Ceylon)
Baker, FBI No. 1863, Vol. 5: 229
Plate 48, fig. 12

LOCAL NAMES. *Mā nila goya* (Sinhala); *Kāriṭṭa parā* (Tamil).

SIZE. Pigeon +; length c. 36 cm. (14 in.).

FIELD CHARACTERS. A dark forest pigeon very like 521 (also with a prominent black-and-white 'chessboard' on hindneck) but dark slaty grey above, lacking any brown on the mantle. Head and neck glossy lilac turning to green. Hindneck, below the 'chessboard', and upper back richly glossed with reddish lilac. *Below*, reddish grey; breast darker and glossed with reddish lilac; abdomen paler; under tail-coverts darker; wing-lining blackish brown. Sexes alike.

Young (immature) duller, with only a trace of the black-and-white chessboard on hindneck.

STATUS, DISTRIBUTION and HABITAT. 'Species peculiar to Ceylon. Resident in the Hill zone. Plentiful in the mountain forests [usually above 1200 m.] especially around Nuwara Eliya and the Horton Plains; occasionally wanders down to the foothills as low as 1000 ft. [c. 300 m.]' — Phillips, 1952.

GENERAL HABITS and FOOD. As in Nilgiri Wood Pigeon (321), q.v.

VOICE and CALLS. Rather silent except for a deep, rather owl-like *hoo* uttered when courting (Henry).

BREEDING. Season 'February, March and August to November, but chiefly during October' (Phillips). *Nest* and *egg* (a singleton) as in 521. Size c. 39 × 29 mm.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

MEASUREMENTS

♂ ♀ Wing 182-208; bill (from feathers) c. 15-17 mm. (Baker).

1 ♀ Wing 199; bill (from skull) 26; tarsus 26; tail 138 mm. (HW).

COLOURS OF BARE PARTS. 'Iris pale red; orbital skin dull pink. Bill plumbeous; apical portion bluish. Legs and feet pinkish fleshy, toes and soles red; legs sometimes white with the fronts of the tarsus and tops of the toes reddish' (Legge).

523. Nepal or Ashy Wood Pigeon. *Columba pulchricollis* Blyth

Columba pulchricollis 'Hodgson' = Blyth, 1846 (1845), Jour. Asiat. Soc. Bengal 14 (2): 866 (Wooded region of eastern Himalaya, i.e. Nepal)
Baker, FBI No. 1864, Vol. 5: 230
Plate 48, fig. 8

LOCAL NAMES. *Ke-o* (Lepcha); *Dashukuruma majungbi* (Cachari); *Pukurr* (Dafila).

SIZE. Pigeon +; length c. 36 cm. (14 in.).

FIELD CHARACTERS. A Himalayan forest pigeon. *Above*, dark ashy or slaty grey, with pale grey head and nape. A conspicuous buff collar, broad and stippled with blackish behind, narrow in front. Upper back below this

136

COLUMBIFORMES

FIELD CHARACTERS. Male (Adult). *Above*, crown and nape greyish white; upperparts rich chestnut-brown with dark slaty rump and blackish brown tail. *Below*, vinous-chestnut. Entire plumage with brilliant metallic green and amethyst sheen.

Female somewhat smaller and duller. Head browner grey with a lilac gloss.

Young (immature) like female but with head more or less unicolorous with body. Juveniles in first plumage very dull and brown with the wing-coverts and scapulars

marginated with rufous.

STATUS, DISTRIBUTION and HABITAT. Resident but very local; Bihar, Orissa, eastern Madhya Pradesh (Bastar dist.), W. Bengal, Assam, Nagaland, Manipur, Mizo (?) and E. Pakistan; from plains level up to c. 1600 metres. Affects forested tracts interspersed with scrub jungle and cultivation, and wooded ravines with dense evergreen undergrowth.

Extralimital. Burma, Thailand, Laos, northern Malaya, central Vietnam.

GENERAL HABITS. Usually keeps singly, occasionally in small parties; local gatherings of 30 or 40 birds where food is abundant, e.g. in patches of gregarious bamboo seeding. Feeds up in fruiting trees as well as by gleaning on the ground. Sits quietly, concealed among the foliage, flying out on an observer's close approach and resettling in another tree a short distance away. Flight comparatively slow, reminiscent of Green Imperial Pigeon's.

FOOD. Wild figs and other fruits and berries (those of *Litsea nitida* specifically recorded); also bamboo seeds, paddy, and other grains.

VOICE and CALLS. 'Rather similar [to *Ducula aenea*'s] though notes not so loud nor so prolonged' (Mooney, 1934, JBNHS 37: 735). 'A soft mew, not unlike that of *Carpophaga [Ducula] aenea*, only not half so loud or booming' (Bingham, 1880, SF 8: 196).

BREEDING. Season, May to July-August. *Nest*, the usual flimsy pigeon structure of twigs, placed fairly low down — normally under 6 metres — in a tall bush or bamboo clump in forest. *Egg*, a singleton, pure white; according to Baker occasionally two. Average size of 15 eggs 37.6 × 29.2 mm. (Baker). No other precise information.

MUSEUM DIAGNOSIS

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♂	210-236	c. 16-17	c. 23-25	152-178 mm.
♀ ♀	203-225	—	—	— (Baker)

Weight c. 13-18 oz. (c. 370-510 gm.).

COLOURS OF BARE PARTS. Iris creamy yellow, orange-yellow or orange-red; orbital skin greyish magenta, eye-rim brighter. Bill: cere and base magenta, rest pale horn or old ivory colour. Legs and feet crimson-magenta; claws pale horn.

PIGEONS, DOVES

137

525. **Andaman Wood Pigeon.** *Columba palumboides* (Hume)¹
Carpophaga palumboides Anonymous = Hume, 1873, Stray Feathers 1: 302
(Port Mouat, Andaman Islands)
Baker, FBI No. 1866, Vol. 5: 233
Plate 48, fig. 13

LOCAL NAMES. None recorded.

SIZE. Pigeon +; length c. 41 cm. (c. 16 in.).

FIELD CHARACTERS. A dark fruit-eating pigeon, confusingly like Nicobar Green Imperial (508) especially when seen from below perched on a high tree.

Male (adult). *Above*, head and neck all round pale grey with a slight metallic green gloss, especially on lower hindneck. Rest of upperparts blackish with dark slaty rump, the feathers edged with metallic green and amethyst gloss ('scalloping'). *Below*, underparts from lower neck down slaty grey with metallic emerald-and-purple sheen. Wing-lining dark slaty.

Female has the head and neck darker grey.

Young (immature) duller coloured overall, with the head and neck still darker and brownish.

STATUS, DISTRIBUTION and HABITAT. Resident; Andaman and Nicobar Islands, comparatively scarcer than Green Imperial in both groups. Wanders from island to island with availability of food — ripening of the different fruits and berries. Affects dense evergreen forest.

GENERAL HABITS. Arboreal and entirely frugivorous. Seen in pairs and small parties in forest trees, often perching at lower heights than Green Imperial. Flies high up in the air while crossing the straits from one island to another.

FOOD. Wild figs and other fruits and berries. Abdulali obtained fruits of *Leae* sp. and *Syzygium cumini* from crops of specimens killed, and Davison 'several fruit about the size of a walnut, two of these with stalks about 2 inches long and as thick as a goose-quill, attached'.

VOICE and CALLS. 'A deep *whoom* without the preliminary *gr* of *Ducula [aenea andamanica]*' (Abdulali, 1964, JBNHS 61: 526).

BREEDING. Unrecorded.

MUSEUM DIAGNOSIS. See Key; for details of plumage Baker, loc. cit.

MEASUREMENTS

♂ ♀ Wing 241–258 mm. (Baker).

Weight 1 lb. 2 oz. (c. 510 gm.) — Davison; 1♂ 520 gm. (Grubb).

COLOURS OF BARE PARTS. Iris orange, reddish yellow or orange-pink. Bill: cere and base lake red or pinkish lilac, rest yellowish white. Legs and feet fleshy pink redder in front; claws horny white.

Genus *MACROPYGIA* Swainson

Macropygia Swainson, 1837, Classif. Bds. 2: 348. Type, by subsequent designation, *Columba phasianella* Temminck, 1824, pl. col. 100

Distinguished by the long graduated tail, exceeding the wing in length. Rump feathers spinous; tail-coverts elongate. Head small and dove-like. Bill slender.

¹ On the basis of some comparative material obtained by him recently in the Andamans and Nicobars, Abdulali (1967, JBNHS 64(2): 166) seeks to resuscitate the race *nicobarica* Walden collected on Trinkat and Nancowry, which was suppressed by Hume (1874, SF 2: 498–9). It was originally described, *inter alia*, as having the entire head, nape, cheeks and neck dark French-grey and wanting the pearly white or greyish white head, throat and nape of *palumboides*.

PIGEONS, DOVES

139

Assam 2 eggs stated to be not uncommon. Pale buff to *café-au-lait* in colour, smooth-surfaced long narrow ovals. Average size of 200 eggs 35.3 × 25.4 mm. (Baker). Both sexes incubate and feed the young. Incubation period unrecorded. Aerial display of male, as described by Baker, of the same general pattern as, e.g. in Ring Dove (534) but with his feathers fluffed out 'until the shiny ones on his rump stand out like a lady's powder-puff'.

MUSEUM DIAGNOSIS. See Key; for details of plumage Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂♂	177–203	13–15	c. 16–18	200–210 mm.
♀♀	191–200	—	—	—

(Baker)

6 recent specimens from Nepal, Sikkim and Bhutan give Wing 4 ♂♂ 196–209; 2 ♀♀ 191–200 mm. Weight c. 200 gm. (SA).

COLOURS OF BARE PARTS. Iris outer ring pink, inner pale blue (sometimes brown); ocular skin grey, eyelids purple. Bill leaden black. Legs and feet dull cherry-red or purplish brown; claws horny black.

MACROPYGIA RUFIPENNIS Blyth

Key to the Subspecies

Crown of male glossed with lilac-purple *M. r. rufipennis*
Crown of male without such gloss.....*M. r. andamanica*

527. **Nicobar Cuckoo-Dove.** *Macropygia rufipennis rufipennis* Blyth

Macropygia rufipennis Blyth, 1846, Jour. Asiat. Soc. Bengal 15: 371 (Southern Nicobars)
Baker, FBI No. 1885, Vol. 5: 255
Plate 49, fig. 10

LOCAL NAMES. None recorded.

SIZE. Same as 526; length c. 41 cm. (16 in.).

FIELD CHARACTERS. A slender reddish brown long-tailed pigeon.

Male (adult). *Above*, whole head and hindneck chestnut, glossed with metallic lilac-purple on crown. Rest of upperparts dark brown (more rufous on wing-coverts, rump, and tail) minutely speckled and barred with black and rufous-buff on hindneck and upper back. *Below*, chin and throat whitish; rest of underparts rufous-buff wavyly cross-barred with black; sides of neck and breast with metallic gloss. Under tail-coverts, wing-lining and wing-quills conspicuously ferruginous-red in flight.

Female. *Above*, head variously mottled with black; neck all round lightly streaked with brown; stipplings on upper back more pronounced and bar-like in character. *Below*, more chestnut than male, and unbarred.

Young (immature). Overall more rufous than adults. Feathers of head and neck edged with black; upperparts more heavily barred; wing-quills edged and tipped with rufous.

STATUS, DISTRIBUTION and HABITAT. Species peculiar to the Andaman and Nicobar Islands, and this race to the latter group. Affects heavy evergreen forest and secondary jungle.

138

COLUMBIFORMES

Tarsus short and partly feathered; feet adapted for perching: toes long, soles broad.

Key to the Species

Central tail-feathers banded throughout with black and rufous *M. unchall*
Central tail-feathers not banded.....*M. rufipennis*

526. **Bartailed Cuckoo-Dove.** *Macropygia unchall tusalia* (Blyth)

Columba tusalia 'Hodgson' = Blyth, 1843, Jour. Asiat. Soc. Bengal 12 (2): 936 (Darjeeling)
Baker, FBI No. 1884, Vol. 5: 253
Plate 49, fig. 8

LOCAL NAMES. *Tusal* (Nepal); *Phoochong-pho*, *Ka-er* (Lepcha); *Pumot* (Bhutes); *Dastukum laima* (Cachari).

SIZE. Pigeon ±; with longer, pointed tail; total length c. 41 cm. (16 in.).

FIELD CHARACTERS. A slender reddish brown long-tailed pigeon.

Male (adult). *Above*, forehead buff shading to lilac-purple on crown and hindneck, highly glossed with metallic green. Rest of upperparts rufous, barred with black. Tail long, broad, graduated, barred with brownish black and rufous. *Below*, chin and throat lilac-buff. Upper breast metallic lilac, changing to dull lilac on lower breast and to buff on lower abdomen, vent, and under tail-coverts.

Female has the upperparts duller; head and breast barred with dark brown.

Young (immature) like female but duller overall, with no trace of metallic gloss.

STATUS, DISTRIBUTION and HABITAT. Resident: Himalayas from Kashmir eastward through Garhwal, Kumaon, Nepal, Sikkim, Bhutan and NEFA; Assam hills south of Brahmaputra river (Garo, Khasi, etc.), Nagaland, Manipur, Mizo (?); E. Pakistan — between c. 450 and 2700 metres. Affects dense evergreen forest and secondary jungle.

Extralimital. W. Szechuan (?), Burma, N. Thailand.

GENERAL HABITS. Keeps in pairs, small parties, and flocks of up to 10 or so. Feeds on the ground by gleaning in cultivation clearings and open glades in forest; also in trees like green pigeon, clambering about among the fruit-laden twigs, sometimes hanging upside down and swinging out for a berry just out of reach. Very jealous of its feeding tree, attacking and chasing off bulbuls and other birds arriving in the same quest. Extended flight fast and pigeon-like, but when moving from tree to tree the habit of gliding upwards to settle on a branch very cuckoo-like. Hind aspect of the bird, perched upright, also strongly reminiscent of a hepatic cuckoo. Silent except in the breeding season.

FOOD. Grain, seeds, shoots, buds, acorns, small drupes and berries.

VOICE and CALLS. Described as a very deep *croo-umm*, the second syllable a booming note, audible a long way off. Heard in the distance only as a low, muffled, single *hu* or *umm* repeated at short intervals.

BREEDING. *Season*, chiefly May to July. *Nest*, the typical flimsy platform of twigs with a slight central depression, placed c. 2 to 8 metres up in a sapling or stunted oak growing in forest. *Eggs*, normally a singleton; in

COLUMBIFORMES

140

GENERAL HABITS. As of 526, q.v.

FOOD. Various fruits and berries, those of *Vitis* and *Leae* spp. identified in crops (Abdulali); bird's-eye chilli (*Capsicum fastigiatum*) growing commonly in secondary jungle and on the edge of clearings, evidently the staple food locally (Davison).

VOICE and CALLS. Unsatisfactorily described as 'peculiar, somewhat resembling that of *Cuculus canorus*, the Common Cuckoo' (B. B. Osmaston). A hoarse, deep, subdued croaking only audible at close range 'resembling o-o-o-o-ah repeated several times successively' (Blyth).

BREEDING. No data.

MUSEUM DIAGNOSIS. See Key to the Species; for details of plumage, Baker loc. cit.

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	180–193	12–13	c. 23–25	210–233 mm. (Baker)

Weight 8–10 oz. (c. 230–285 gm.).

COLOURS OF BARE PARTS. 'Iris violet or light blue with an inner ring of carmine. Bill dull horny or purplish red, paler at gape. Legs and feet, dull pinkish red in front, bright pale pink behind, soles still paler' (Baker).

527a. **Andaman Cuckoo-Dove.** *Macropygia rufipennis andamanica* Abdulali

Macropygia rufipennis andamanica Abdulali, 1967, Jour. Bombay nat. Hist. Soc. 63 (2): 421 (Betapur, Middle Andamans)

SIZE and FIELD CHARACTERS. As of 527, q.v.

STATUS, DISTRIBUTION and HABITAT. Race peculiar to the Andaman Is. BREEDING. A male collected by Abdulali in the Middle Andamans on 24 February had enlarged testes.

MUSEUM DIAGNOSIS. Lacks the lilac-purple gloss on the crown of the male, described as a character of the Nicobar population.

Genus *STREPTOPELIA* Bonaparte

Streptopelia Bonaparte, 1855, Compt. Rend. Acad. Sci. Paris 40: 17; id., *Conspectus* Av. 2: 63. Type, by subsequent designation, *Columba risoria* Linnaeus
Oenopelia Blanford, 1898, Fauna Brit. Ind., Bds. 4: 28 (in key): 47. Type, by monotypy, *Columba tranquebarica* Hermann

Doves of this genus differ from *Columba* chiefly in smaller size, comparatively small head and slender neck, and weaker narrower bill. Wing relatively long and narrow:

Sole of foot of *S. r. risoria* (537), × c. 1

PIGEONS, DOVES

141

2nd and 3rd primaries (as.) longest. Tail considerably graduated, never exceeding two-thirds length of wing. Feet well adapted for walking: tarsus stout and short, toes narrow. All the species are grey or brown in colour with a dark narrow collar or a patch ('chestboard') of black-and-white or rufous feathers on the neck. The genus contains both resident and migratory forms.

LOCAL NAMES. None recorded.

SIZE. Pigeon —; length c. 28 cm. (c. 11 in.).

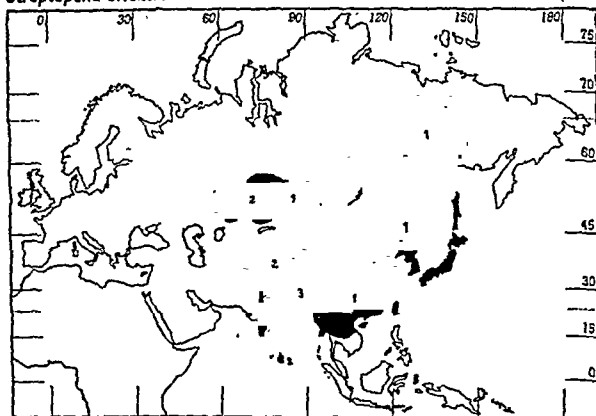

FIELD CHARACTERS. A small, rather slender pinkish and ashy grey pigeon with a patch of white-spotted black feathers on either side of base of neck, looking like miniature chessboards. Upperparts rufous with blackish centres to the feathers, and contrasting ashy grey wing-coverts. Tail black, graduated, with broad white terminal border conspicuous in flight especially when spread before alighting. Sexes alike.

Confusingly like *S. orientalis*, and field identification except by experienced experts unreliable.

¹ *Streptopelia turtur turtur* (Linnaeus) was included in FBI 5: 236 and then in Synopsis (No. 528) on the strength of a single specimen obtained at Quetta (N. Baluchistan) by Swinhoe. Dr Ticehurst examined this skin in the British Museum and found it inseparable from some examples of the race *arenicola*. Since Quetta would be well over 1000 miles beyond the range of nominate *turtur*, we agree with Dr Ticehurst that it would be more satisfactory to delete this form from the Indian list.

PIGEONS, DOVES

143

Streptopelia orientalis

■ Breeding and wintering ranges (see text) 1 *S. o. orientalis* (530).
2 *S. o. meena* (531). 3 *S. o. agricola* (532). 4 *S. o. erythrocephala* (533).

328), northern Sikkim, northern Bhutan, and NEFA, but the population there largely intermediate with resident *agricola* (532), in addition to being subject to a considerable amount of individual variation; specimens usually impossible to assign to either race with conviction.

Extralimital. Breeds in central Siberia, Transbaikalia, Amurland, south to SE. Tibet, Yunnan, and across to Japan.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 531, 532, qq.v.

MUSEUM DIAGNOSIS. See Key; very similar to *agricola* but has the crown and nape clinically greyer, and the rufous margins of upper wing-coverts more greyish.

MEASUREMENTS

Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀ 180-198	15-17	25-28	c. 130-145 mm. (Hartert)

COLOURS OF BARE PARTS. As in 532.

531. Western Turtle-Dove. *Streptopelia orientalis meena* (Sykes)

Columba meena Sykes, 1833 (1832), Proc. Zool. Soc. London, pt. 2: 149 (Dukhun)

LOCAL NAMES. *Kāla fākhā, Barko fākhā* (Hindi); *Wān kūl, Gūgi, Jāngū kōnkī, Kāmār, Kāmra* (Kashmir).

SIZE. Pigeon; length c. 33 cm. (13 in.).

142

COLUMBIFORMES

STATUS, DISTRIBUTION and HABITAT. A vagrant in winter, or straggling passage migrant, in W. Pakistan (Gilgit, Afghanistan frontier, N. Baluchistan). Affects open cultivated country.

Extralimital. Breeds in N. Africa from Morocco to Tripoli; in SW. Asia from the Kirghiz Steppes and Turkestan south to Iraq, Persia, Afghanistan and Yarkand (Peters).

GENERAL HABITS and FOOD. As in other members of the genus, qq.v. A migrant form.

VOICE and CALLS. A continuous and rhythmic 'deep crooning or purring note *roo-rrrr, roo-rrrr, roo-rrrr*' (Witherby, for nominate race) heard chiefly in the breeding season.

BREEDING. Extralimital.

MUSEUM DIAGNOSIS. See Keys to the Species and Subspecies; for details of plumage Baker, loc. cit.

MEASUREMENTS

Wing ♂ ♀ 163-177 mm. (Hartert).

7 adult specimens from Afghanistan give: Wing 5 ♂ 169-173; 2 ♀ 166 mm.

Weight 111 (1), 121-140 gm. (Paludan, 1959).

COLOURS OF BARE PARTS. Iris deep or brownish orange; orbital skin purple-brown, eye-rim reddish brown. Bill greyish or slaty black, purple-red at gape. Legs and feet purple or reddish purple, soles paler; claws horny brown.

Cf. Whistler, H., and Kinnear, N. B., 1936, JBNHS 38: 677-9
Baker, FBI No. 1870, Vol. 5: 238

LOCAL NAMES. As for 531.

SIZE. Pigeon; length c. 33 cm. (13 in.).

FIELD CHARACTERS. As of 531, q.v., but with dove-grey tips to tail-feathers instead of white.

STATUS, DISTRIBUTION and HABITAT. Evidently only a winter visitor to ? Nepal (a pair in Kathmandu Valley — October, Fleming, JBNHS 65(2):

144

COLUMBIFORMES

FIELD CHARACTERS. A large reddish brown dove with scaly-patterned upperparts, black 'chessboards' on sides of neck, and broad white terminal border to the rounded tail—conspicuous when spread while alighting. Distinguished from the rather similar and commoner Spotted Dove (537) by rich rufous coloration and stocky pigeon-like build.

Adult. Above, head and neck vinous-brown, greyish on forehead and crown; a grey-spotted black patch on either side of hindneck. Mantle rufous-brown with dark centres to the feathers producing a scaly pattern; lower back and rump slaty grey; tail largely blackish brown with terminal white band. Below, chin and centre of throat whitish; foreneck and breast pale vinous-rufous passing to whitish on abdomen and white on under tail-coverts. Sexes alike.

Young (immature) browner and less rufous, lacking the grey on head and rump, and also the checkered neck-patches. Feathers of back, wing-coverts, and breast with pale margins.

STATUS, DISTRIBUTION and HABITAT. Resident and breeds in the western Himalayas up to c. 4000 m. from the Afghan frontier in W. Pakistan eastward through Kashmir (also in Baltistan and Ladakh as far as Leh), Garhwal and Kumaon to central Nepal where it meets and intergrades with the richly coloured east Himalayan form *agricola* (532). Migrates south in winter, its numbers augmented by extralimital immigrants, and spreads widely over northern and peninsular India, chiefly on the western side, south to Mysore. Rare vagrant to Ceylon; only four records in the last 90 years, the last in December 1954. Affects open mixed deciduous and bamboo forest, particularly broken foothills country and the neighbourhood of cultivation. Avoids semi-desert tracts.

Extralimital. 'Breeds in the southern part of western Siberia east to western Altai; Turkestan, Persia, Afghanistan...' (Peters).

MIGRATION. No ringing records. 'Small numbers migrate through Kohat from mid April till the 3rd or 4th of May, returning in September and October' (Whitehead). 'None had arrived about Leh by the middle of May' though common there and in full moult [post-nuptial] in early August (Meinertzhagen).

GENERAL HABITS. A ground-feeding granivorous dove. Keeps in pairs and small parties, forming into larger flocks when migrating. Gleans scattered grain and weed seeds in stubbles and on shaded dusty cart-tracks connecting forest villages etc. Also commonly frequents the *parāos* or bivouac sites of bullock-carts along country roads to glean the spillage from the grain sacks etc. Flight swift and direct, typical of the pigeons. In courtship male bows and bobs ludicrously in front of the female as he advances towards her in stiff mincing hops, calling with goitred-out throat—an action rather reminiscent of a *Calotes* lizard. Also has the characteristic aerial display of the doves, springing up into the air with clapping wings and coasting down in an arc or wide spiral with fanned-out tail.

FOOD. Paddy and other cereals, weed and bamboo seeds, and green shoots.

VOICE and CALLS. Commonly heard at Himalayan hill-stations: a hoarse, rather mournful *goor*... *gūr-gūgūgū* repeated in slow runs, the final *gūgū* particularly mournful-sounding and as though uttered with intake of breath.

PIGEONS, DOVES

145

BREEDING. *Season*, principally May to June-July. *Nest*, a flimsy platform of twigs, placed in a sapling or scrubby bush or bamboo clump in fairly open forest, as a rule under c. 3 or 4 metres from the ground. *Eggs*, almost invariably two, white, of the typical oval shape of pigeons' eggs. Average size of 40 eggs 32.2 × 23.9 mm. (Baker). Both sexes share in incubation and tending the young. Incubation period unrecorded.

MUSEUM DIAGNOSIS. Distinguished from the other races by conspicuously paler underparts, much white on belly, white under tail-coverts, and white tips to the tail-feathers.

Chick. 'Down long, plentiful, hair-like, yellowish white. Whole body covered except sides of head, centre of abdomen and breast, chin and upper throat. Distribution and character as in the Columbae' (Ticehurst).

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
10 ♂♂	ad. 185-207 (av. 196.2)	c. 22-23	c. 26-28	c. 122-140 mm. (SA)

Weight 165-229 gm. (Paludan, 1959).

COLOURS OF BARE PARTS. Iris orange; ocular skin magenta. Bill: base and cere magenta, distal half horny brown. Legs and feet magenta, hind tarsus paler and pinkish; claws horny brown.

532. Rufous Turtle-Dove. *Streptopelia orientalis agricola* (Tickell)

Columba agricola Tickell, 1833, Jour. Asiat. Soc. Bengal 2: 581
(Jungles of Borahhūm and Dholbūm)

Streptopelia orientalis meridionalis Koelz, 1954, Contrib. Inst. Regional Exploration, No. 1: 28 (Sangau, Lushai Hills)

Streptopelia orientalis khasiana Koelz, 1954, Contrib. Inst. Regional Exploration, No. 1: 28 (Mawryngkneng, Khasi Hills)

Baker, FBI No. 1872, Vol. 5: 240 (= *merula*)

Plate 49, fig. 16

LOCAL NAMES. *Rām ghūghū* (Bengal); *Dantu gajao* (Cachari); *Piko* (Assam); *Inruikū* (Naga); *Veh gūra* (Kuki); *Hāruā kōpu* (Nowgong, Assam); *Khumi chaphubi* (= 'the pot pigeon', alluding to likeness of coloration to red earthenware pot burnt blue in patches); *Leina khumi* (= 'the goddess pigeon' — Manipur).

SIZE. Pigeon; length c. 33 cm. (13 in.).

FIELD CHARACTERS. A stocky rufous dove like 531, q.v. — also with black-and-whitish chessboard on either side of neck — but more richly coloured and with slaty border to tail instead of white. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Resident and breeds in the Himalayas to c. 4000 m. alt. from central Nepal [where it intergrades with the paler *meana* (531)] eastward through Sikkim, Bhutan and NEFA; also in the Assam hills south of Brahmaputra R. to c. 1300 m. alt., Nagaland, Manipur, Mizo, E. Pakistan. Affects oak and other mixed deciduous forest, often around cultivation. Migrates in winter southward into peninsular India, chiefly on the eastern side. Winter range unclear owing to intermingling then with the very similar resident peninsular race *erythrocephala* (533).

10

PIGEONS, DOVES

147

MUSEUM DIAGNOSIS. Distinguished from the equally richly coloured *agricola* (and/or *eritralis*) by vinous-red crown, nape, and mantle without any trace of grey. Edges to scapulars, wing-coverts, and tertiaries deeper red. Vinous-red of underparts much redder.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	183-193	22-24	25-28	122-134 mm.
♀♀	179-190	22-23	26-27	112-127 mm.

10 ♂♂ (Orissa, M.P., Mysore) average wing 189.1, tail 126.4 mm.; 5 ♀♀ wing 183.8, tail 120 mm. (SA).

Weight 4 ♂♂ 173-206 gm. (SA).

COLOURS OF BARE PARTS. As in 531.

534. Indian Ring Dove. *Streptopelia decaocto decaocto* (Frivaldszky)

Columba risoria Linnaeus, 1758, Syst. Nat., ed. 10, 1: 65 (India). [Based on a pale domesticated bird.]

Columba risoria L. var. *decaocto* Frivaldszky, 1838 (1834-6), K. Magyar Tudos Társaság Evkönyvi, 3: 183, pl. 8 (Turkey)

Baker, FBI No. 1879, Vol. 5: 248

Plate 49, fig. 12

LOCAL NAMES. *Dhēr fāktā*, *Pārki*, *Pāndūk*, *Gūgi* (Hindi); *Kēkil* (Kashmir); *Gero* (Sind); *Jāngli kápōth* (Baluchi); *Doalo*, *Doale* (Bihar); *Pār ghūghū* (Bengal); *Pithā hālā*, *Kānda* (Marathi); *Dhāl* (Gujarati); *Peddā killa gūcā* (Telugu); *Kelli pūrā*, *Sāmbel pūrā* (Tamil, Ceylon); *Pettanckengūli* (Malayalam); *Māhā kōtōyā* (Sinkhala); *Dasta gēphu* (Cachari); *Set kōpu* (Assam).

SIZE. Pigeon —; length c. 32 cm. (12½ in.).

FIELD CHARACTERS. A pale grey and brown pigeon distinguished by a prominent narrow black half-collar on hindneck. Breast lilac passing into ashy grey on abdomen and darker grey on vent and under tail-coverts. Broad white terminal edge to blackish tail conspicuous in flight, especially when spread while alighting. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Resident but subject to marked seasonal migrations, altitudinal and presumably of a local character. Found in appropriate biotopes throughout both Pakistans, the entire Indian Union, and Ceylon. Not recorded in Sikkim or Bhutan, and only as occasional post-monsoon visitor to Nepal Valley. Absent in the Andaman, Nicobar, Laccadive, and Maldivé islands. Occurs up to c. 2400 m. alt. (rarely to c. 3000 m.) in the western Himalayas in summer, in Kashmir then almost completely replacing *S. eritralis rufina* below c. 1800 m.

Affects open, cultivated, essentially dry deciduous country (even semi-desert) with groves or a scattering of babool (*Acacia*), dhāk (*Butea*) and similar trees, commonly sharing these facies with Little Brown Dove (541). Avoids moist evergreen tracts.

Extremal. 'Resident from Hungary over SE. Europe, Asia Minor, Turkestan, N. China and Japan; south to Palestine, Iraq, Persia . . . and W. China' (Peters). Within the last decade has 'exploded' phenomenally all over Europe, now breeding regularly as far west as Great Britain, and north to Scandinavia.

146

COLUMBIFORMES

Extremal. Burma south to Tenasserim.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 531. In captivity 'Besides the usual coo they will, when annoyed, utter a sharp noise like the twang of a banjo string' (Ludlow).

BREEDING. *Season* and *Nest* as in 531. Average size of 11 eggs (*orientalis*, Gyanse) 33.5 × 24.5 mm. (Ludlow).

MUSEUM DIAGNOSIS. Intermediate between *rufina* and nominate *orientalis* and merged by some authors with the latter. Markedly richer coloured than 531. Crown and nape grey; abdomen grey; thighs, under tail-coverts, and terminal fringe of tail slaty grey. Individual specimens of the two could be assigned to either form.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	166-198	22-24	c. 26-27	135-140 mm.
♀♀	164-191	22-24	26-27	112-132 mm.
		(once 28)	(once 30)	(SA)

Weight c. 200-210 gm.

10 ♂♂ (Sikkim) average wing 183.9 mm. (Stresemann).

COLOURS OF BARE PARTS. As in 531.

533. Peninsular Turtle-Dove. *Streptopelia orientalis erythrocephala* (Bonaparte)

Turtur erythrocephalus Bonaparte, 1855, Cons. Gen. Av. 2: 60 (South Africa in error southern India vide Whistler, H., 1943, JBNHS 44: 26). Restricted to Mysore by Ripley. Type in British Museum Not in Baker, FBI

LOCAL NAMES. As for the other races where applicable.

SIZE. Pigeon; length c. 33 cm. (13 in.).

FIELD CHARACTERS. A stocky rufous dove, practically indistinguishable from 532 when both together in winter except by redder forehead and crown. See Museum Diagnosis. Both distinguished from 531 by richer coloration and slaty grey (c. white) fringe to tail. Sexes alike.

Young (immature) like juvenile *meana* (531) but brighter rufous overall with faint rusty edges to slaty feathers of rump and upper tail-coverts, and marked rufous wash on central pair of rectrices.

STATUS, DISTRIBUTION AND HABITAT. Resident and breeds in peninsular India from Bihar and Orissa south to Mysore. Has not yet been procured in western India north of Castle Rock (c. 15°N. lat.) nor in the Bombay Deccan, but range not properly worked out. Local movements unknown. Affects open mixed deciduous forest and bamboo jungle in the neighbourhood of cultivation.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in the other races q.v.

BREEDING. *Season* in Bihar, Orissa and Madhya Pradesh as well as Mysore November to January/February, but possibly not well defined. *Nest*, the usual skimpy pad of twigs placed fairly low down (c. 2 to 4 m.) in a bushy sapling or shrub, or up in a bamboo clump. *Eggs*, normally 2, very rarely 3, white, as in other races. Measurements not available.

148

COLUMBIFORMES

GENERAL HABITS. One of our commonest doves; very plentiful in some areas, inexplicably scarce in others outwardly just as suitable. Keeps in pairs or small parties — often in company with other doves — gleaning in paddy stubbles, newly sown millet fields, or fallow land often in the environs of towns and villages. The birds perch freely on the buildings, and boldly enter cattle sheds and verandas and courtyards of rustic dwellings to feed within an arm's length of the occupants. Occasionally gathers in large flocks, maybe of a hundred or more, where food is particularly abundant, or when preparing for one of its local migrations. Flight characteristically pigeon-like, strong and direct, with rapid steady wing-beats — and high up in the air when migrating. Courtship display on ground consists of the male bowing and bobbing to the female, cooing with inflated throat and depressed tail as he advances on her in stiff ludicrous hops punctuated by a mincing step or two. Also displays in the air, springing up from a tree-top or post at a steep angle with a loud clapping of wings and then coasting down with tail fanned-out in a graceful arc or wide spiral to the accompaniment of an aggressive-sounding nasal *koon-koon-koon*. Very pugnacious when nesting, chasing an intruder in its territory with vigour and determination, literally from 'pillar to post', accompanied by the strident challenging *koon-koon* as 'war cry', until he is driven off. On the ground the rivals side up to one another rather surreptitiously, then suddenly jump up and lash out viciously with the wings, each ducking in turn to avert the coming onslaught, one bird frequently jumping clean over the other in the excitement of these comical antics. Often seen in hot pursuit of a crow making off with an egg or chick filched from its nest, but contact with marauder seldom registered, and even then is so innocuous as to leave the crow mildly surprised and not at all repentant!

FOOD. Grain and seeds. Stomachs examined at Pusa in Bihar contained chiefly wheat, barley, and paddy grains, and seeds of mustard, linseed and various weeds (Mason & Lefroy, 1912). Toria (*Brassica campestris*) at time of threshing (Afzal Husain & Bhalla, 1937).

VOICE AND CALLS. 'Song' a deep, pleasant *kūkoo . . . kook* repeated several times in runs. A strident *koon*, *koon* in aggression and aerial display.

BREEDING. Breeds throughout its range — up to c. 2400 m. alt. in Kashmir and the western Himalayas. *Season*, in the northern areas with a definite cold winter May to September, chiefly May-June. Elsewhere, and in peninsular India, practically all year; in Ceylon December to May, chiefly April and May. *Nest*, a flimsy-bottomed sketchy pad of twigs usually placed low down in a *Euphorbia* bush or small tree such as babool (*Acacia*); occasionally on rafters in a cattle-shed or outhouse. *Eggs*, normally 2, exceptionally 3, pure white, smooth-textured. Average size of 60 eggs 30.1 × 23.2 mm. (Baker). Both sexes share in nest-building and incubation; period unrecorded.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	160-174	20-23	21-24	116-134 mm.

No disparity in the sexes, but tail of ♀♀ averages shorter.

(SA, HW)

PIGEONS, DOVES

149

Weight 2 o? 127; 138 gm. (SA).

COLOURS OF BARE PARTS. Iris lake red to crimson; edge of eyelid red; narrow circumorbital skin greyish pink. Bill brownish black. Legs and feet dark pinkish red or magenta; claws black.

STREPTOPELIA TRANQUEBARICA (Hermann)

Key to the Subspecies

Paler, especially on the lower parts.....*S. t. tranquebarica*
Darker and more red, especially on the lower parts.....*S. t. humilis*

535. Indian Red Turtle-Dove. *Streptopelia tranquebarica tranquebarica* (Hermann)

Columba tranquebarica Hermann, 1804, Obs. Zool.: 200 (Tranquebaria, India)
Baker, FBI No. 1881, Vol. 5: 250

Plate 49, fig. 11

LOCAL NAMES. *Seōti fākhā, Gīrī fākhā, Biki* (Hindi); *Itoā* (Bihar); *Vitākāri konda* (Marathi); *Terra geová* (Telugu); *Powari* (Maria Gond).

SIZE. Myna \pm ; length c. 23 cm. (9 in.).

FIELD CHARACTERS. A small, dainty, brightly coloured grey and pinkish brick-red dove.

Male (adult). Above, head and nape dark ashy grey, with a black collar round hindneck; mantle vinous-red, wing-coverts grey; lower back, rump and upper tail-coverts dark slaty grey. Tail brownish and grey with the outer feathers and a broad terminal band (broken in centre) conspicuously white. Below, vinous-red; chin and vent whitish, under tail-coverts white, flanks grey.

Female pale brownish and grey with hindneck collar and tail as in male. In overall effect a good replica of Ring Dove but smaller and with relatively shorter tail.

Young (immature) like female but feathers of upperparts, wing-coverts and breast narrowly edged with pale fulvous.

STATUS, DISTRIBUTION AND HABITAT. Resident; widely but rather capriciously distributed, and subject to marked local migrations as yet little understood, involving some intermingling and overlap of the races. From West Pakistan (Baluchistan, Sind, Punjab) east through Uttar Pradesh to W. Nepal (?) and Bihar, south through peninsular India to Madras and Mysore. Only a summer (breeding) visitor to the Himalayan duns and foothills, normally under c. 800 m. alt. Rare vagrant to Ceylon; once (c. 1880) recorded breeding in the Jaffna area. Affects open scrub jungle and cultivation in deciduous biotope.

MIGRATION. Only a single definite record: a bird ringed in Bhavnagar, Gujarat (c. 21°45'N., 72°15'E.) 13.ix.1961, recovered near Karachi, West Pakistan (c. 24°37'N., 67°5'E.) 27.iii.1967.

GENERAL HABITS. Similar to (534) but the least common of all the doves and seldom found in close familiarity with man. Associates with Ring and Little Brown Doves to glean in outlying stubble fields and village environs, and on the countryside, in the morning and late afternoon, retiring during the midday heat into the trees and tope dotted around. Usually seen in twos and threes, but flocks and feeding congregations of up to 50 or more,

PIGEONS, DOVES

151

Weight 1 ♂ 104 gm. (GD).

COLOURS OF BARE PARTS. Iris hazel- to dark brown; eye-rim plumbeous. Bill black, tinged with plumbeous at base and on cere. Legs and feet dull red or magenta; claws black.

536. Burmese Red Turtle-Dove. *Streptopelia tranquebarica humilis* (Temminck)

Columba humilis Temminck, 1824, Pl. Col., livr. 44: 259 [but not pl. 258]
(Bengal and Luzon)

T. (urtur) murvensis 'Hodgs.' = Bonaparte, 1856, Compt. Rend. Acad. Sci. Paris 43, no. 20: 942 ('continent [de l'Asie]' = Nepal ex Hodgson), vide Hartert, 1922, Vög. pal. Fauna 3: 2222

Baker, FBI No. 1882, Vol. 5: 251

LOCAL NAMES. *Lāli pōhū, Hārūā kōpū* (Assam); *Daotu kashiba gejao* (Cachari); *Gūlāhī ghūghū, Ikhūyā ghūghū, Tama khari, Lāl ghūghū* (Bengal).

SIZE. Myna \pm ; length c. 23 cm. (9 in.).

FIELD CHARACTERS. As in 535, q.v. — an elegant, brightly coloured little dove, grey pinkish and brick-red overall, with a narrow black collar on hindneck. Female, a smaller replica of Ring Dove.

STATUS, DISTRIBUTION AND HABITAT. Resident and locally migratory; east of range of 535 — Nepal, Sikkim (?), Assam (north and south of Brahmaputra river), Manipur, East Pakistan; Andaman Islands. Summer (breeding) visitor to Nepal Valley, bhabar and duns, and to the Bengal and Assam duars, up to c. 1300 m. altitude. Affects scrub jungle and open cultivated country, as 535.

EXTRALIMITAL. The greater part of SE. Asia: NE. Tibet and N. China south to Burma, Thailand, and the Indochinese countries and N. Philippines (Peters).

GENERAL HABITS, FOOD, VOICE AND CALLS. As in the Indian race (535). BREEDING. Season in northern areas with a cold winter chiefly March to September; elsewhere no fixed period; in the Andamans B. B. Osmaston took eggs between February and April. Nest and eggs as in 535. As in the case of several mild-mannered birds and other dove species, nest often sited in the same tree as holds a drongo's nest (*Dicrurus* sp.) obviously for the protection from crows and other nest robbers afforded by these vigilant and pugnacious guardians.

MUSEUM DIAGNOSIS. Differs from the nominate Indian race in its much darker and richer coloration, above and below. But this variation is clinal and many intermediate individuals are impossible to place with conviction. The axillaries given as white in *tranquebarica* and grey in *humilis* are variable in colour and not infallibly diagnostic.

MEASUREMENTS AND COLOURS OF BARE PARTS as in 535. 'Wing 137-148' (Baker).

STREPTOPELIA CHINENSIS (Scopoli)

Key to the Subspecies

A Wing usually under 130 mm.....*S. c. ceylonensis* 153
B Wing usually over 130 mm.....*S. c. chinensis*

COLUMBIFORMES

Streptopelia tranquebarica

■ Distributional range 1 *S. t. tranquebarica* (535). 2 *S. t. humilis* (536).

mixed with other doves, not uncommon after the harvest. In cold weather they have the common dove habit of sitting with fluffed plumage, bunched like starlings, on bare tree-tops at sunset to warm themselves before retiring to roost. Courtship display as in 534 and other doves; when bowing and bobbing to female, calling with distended throat, looks in the distance as if hammering the ground with the bill.

FOOD. Granivorous: grains of paddy, maize, and other cereals; grass- and weed seeds.

VOICE AND CALLS. A somewhat harsh rolling *gloo-gurr-goo gloo-gurr-goo* quickly repeated several times without interruption — in runs.

BREEDING. Season in northern India, with a cold winter, chiefly April to September; elsewhere more or less all year, the incidence varying locally and individually. Nest as of other doves, a skimpy platform or saucer of twigs and grass-stems placed perhaps somewhat higher up than in others (c. 3 to 7 or 8 metres) near the extremity of a leafy branch. Eggs, normally 2, rarely 3, white, typical. Average size of 49 eggs 25.9 × 19.9 mm. (Baker). Both sexes share in nest-building, incubation and tending the young; incubation period unrecorded.

MUSEUM DIAGNOSIS. Paler than the eastern race *humilis* (536) especially on the underparts, but variation clinal and many individuals impossible to assign definitely. For details of plumage see Baker, loc. cit.

MEASUREMENTS

Back less distinctly spotted with darker buff..... <i>S. c. edwardsi</i>	155
Back spotted very indistinctly or not at all..... <i>S. c. tigrina</i>	154

537. Indian Spotted Dove. *Streptopelia chinensis surattensis* (Gmelin)

Columba surattensis Gmelin, 1789, Syst. Nat. 1 (2): 778
(Surat, Gulf of Cambay, India)
Baker, FBI No. 1873, Vol. 5: 242
Plate 49, fig. 14

LOCAL NAMES. *Chitrāka fākhā, Chitta fākhā, Pārki, Chittā, Kangskiri, Pāndūk* (Hindi); *Chhitā ghūghū, Tēla ghūghū* (Bengal); *Thipkyā kācā* (Marathi); *Chakkara kutta prāru, Aripāru* (Malayalam); *Vānā hāli* (Gujarati); *Bode* (Gond); *Poda bellāgūcā* (Telugu); *Pūli pūrā* (Tamil); *Pāti kōpū* (Assam); *Kedāyā pāndūk* (Bihar); *Daotu* (Cachari); *Inruigu* (Naga); *Voh kūrūp* (Kuki).

SIZE. Pigeon —; slenderer. Length c. 30 cm. (12 in.).

FIELD CHARACTERS. A slender pigeon, above pinkish brown and grey, spotted with white and with a conspicuous black-and-white 'chessboard' at base of hindneck. Tail blackish brown and slate with broad white terminal border which flashes prominently when spread out as bird is alighting. Below, vinous-grey, paler on throat, white on belly, vent, and under tail-coverts. Sexes alike.

Young (immature) paler and browner without the black chessboard on hindneck. Above, barred instead of spotted; wing-coverts edged with rufous. Below, fulvous-brown; breast feathers narrowly fringed with pale fulvous.

For downy chick see Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident; in some areas altitudinal and local migrant. Common in appropriate biotopes throughout West Pakistan (excepting desert and semi-desert areas), and India east to c. Cachar in Assam, including Nepal, Sikkim, and Bhutan, south through the Peninsula to Kanyakumari. Normally to c. 2400 m. alt. in the Himalayas in summer (individual stragglers once observed at c. 4900 m., Lahul, Himachal Pradesh, in June — H. G. Alexander); up to c. 1500 m. in the peninsular hills. Everywhere affects better wooded, better watered facies than Ring and Little Brown Doves — gardens, groves, cultivation and moist deciduous jungle. Habitat preference more clear-cut in dry season.

GENERAL HABITS. Except the preference for moister facies, not appreciably different from other doves. Pairs or small parties glean in stubble fields, on cross-country dust tracks, cartmen's bivouac sites, and in village environs, freely entering courtyards and verandas of inhabited dwellings. When disturbed suddenly on the ground takes off with an explosive flutter of wings and a quick side to side rolling action. Flight, as of other doves, strong and direct with a peculiar jerky saw-toothed action of gliding and abrupt braking with wings and outspread tail when alighting on a branch. Bowing and aerial nuptial displays, and agonistic and territorial behaviour as described under 534.

FOOD. Grains of paddy, jowar and other cereals, lentils and pulses, grass- and weed seeds.

PIGEONS, DOVES

153

VOICE and CALLS. A soft, pleasant though rather mournful-sounding *Krookrük-krookroo* . . . *kroo-kroo-kroo*, the number of the final *kroos* varying from two to six. Pattern of this song common, but individual idiosyncracies very marked; also discrete dialects in different parts of the range.

BREEDING. *Season*, in the northern portions, with a definite cold season, mainly April to July; elsewhere practically throughout the year; evidently two broods (or more ?). *Nest*, the customary flimsy platform of a few twigs and grass-stems with a central depression; placed fairly low down in a tree, thorn bush, or bamboo clump, or in the head of a stunted date palm; commonly also under eaves and on cornices and rafters in verandas of inhabited bungalows. *Eggs*, normally 2, exceptionally 3, white, with a smooth texture. Average size of 100 eggs 27.2 × 21.8 mm. (Baker). Both sexes take part in nest-building, incubation and tending the young. Incubation period c. 13 days; needs confirming.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

Chick. 'Down long, plentiful, hair-like, yellowish white, darker than in *S. orientalis merna*' (Ticehurst).

There is a slight variability in colour and in the amount of spotting on the back and tertiaries; *S. Indian* birds are also clineally somewhat smaller than *N. Indian*, but less markedly so than Ceylonese (538) q.v. Intergrades with the darker *edwardi* (540) in eastern NEFA and Nagaland, and with the Burmese *tigrina* (539) in Manipur and E. Pakistan.

MEASUREMENTS

Peninsular and S. Indian birds measure:

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	135-146	18-21	21-24	118-143 mm.
♀♀	132-143	19-21	20-24	117-133 mm. (SA)

21 examples from Nepal give

11 ♂♂	135-151 (av. 142)	—	—	131-150 mm. (av. 139.5)
10 ♀♀	133-145 (av. 139.2)	—	—	125-141 mm. (av. 134.1) (Biswas)

Weight 3♂♂ 123-128 gm. (GD); 1 o? 116 gm. (SA).

COLOURS OF BARE PARTS. Iris pale reddish brown; eyelids and narrow bare orbital patch dull crimson. Bill dark horny or plumbeous-brown. Legs and feet bright magenta; claws brown.

MISCELLANEOUS. Popular as a cage bird for its song, especially in the eastern portions of its range. Has been introduced as a colonist into Mauritius.

538. **Ceylon Spotted Dove.** *Streptopelia chinensis ceylonensis* (Reichenbach)

Turtur ceylonensis Reichenbach, 1851, Vollst. Natursyst., Tauben, pl. 253b. ff. 3373-4 (Ceylon)

Baker, FBI No. 1876, Vol. 5: 245

LOCAL NAMES. *Alu kobēyā* (Sinhala); *Mani purā*, *Ūmi purā* (Tamil).

SIZE. Pigeon —; slenderer. Length c. 30 cm. (12 in.).

PIGEONS, DOVES

155

coverts the same with pale grey edges instead of all grey as in *suratensis*. White of underparts less in extent and often replaced with pale fulvous-brown.

MEASUREMENTS. Wing ♂♂ 137-155 mm. (Baker).

COLOURS OF BARE PARTS. As in 537.

MISCELLANEOUS. A favourite cage bird for its song throughout its range.

540. **NEFA Spotted Dove.** *Streptopelia chinensis edwardi* Ripley

Streptopelia chinensis edwardi Ripley, 1948, Proc. Biol. Soc. Wash. 61: 99 (Chabua, Lakhimpur dist., NE. Assam)

Not in Baker, FBI

LOCAL NAMES. As under 537 where applicable.

SIZE. Pigeon —; slenderer. Length c. 30 cm. (12 in.).

FIELD CHARACTERS. As of 537. A slender white-spotted pinkish grey and brown pigeon with a conspicuous black-and-white 'chessboard' on hindneck. See Key to the Subspecies, and Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Eastern NEFA, in moist deciduous biotope, chiefly plains and foothills.

Extralimital. Unrecorded; possibly extreme N. Burma, W. China (?).

GENERAL HABITS, FOOD, VOICE and CALLS. As in 537, q.v. Song 'noticeably different from *suratensis* of peninsular India. Ends abruptly with a single *krük* in place of several prolonged *kroos*' (SA). Local dialect?

BREEDING. *Season, nest, and eggs* as in the Burmese race.

MUSEUM DIAGNOSIS. Conspicuously darker on the upperparts than Indian *suratensis*. Terminal bars on feathers of back and median wing-coverts darker buff and much reduced in extent. Differs from Burmese *tigrina* in having the upperparts darker still with more pronounced dark margins to feathers of back.

MEASUREMENTS

10 ♂♂ Wing 141-151; tail 139-146 mm. (SDR).

COLOURS OF BARE PARTS. As in 537.

541. **Indian Little Brown or Senegal Dove.** *Streptopelia senegalensis cambayensis* (Gmelin)

Columba cambayensis Gmelin, 1789, Syst. Nat. I (2): 779 ('Cambaya', i.e. Gulf of Cambay, NW. India)

Baker, FBI No. 1877, Vol. 5: 246

Plate 49, fig. 13

LOCAL NAMES. *Chhīta fākhā*, *Pārki*, *Torrā fākhā*, *Pāndūt* (Hindi); *Tulan ghēri* (Sind); *Chitti bellagūrvā*, *Sowata gūrvā* (Telugu); *Touta purā* (Tamil); *Aripāru* (Malayalam); *Rām kōpū* (Nowgong, Assam).

SIZE. Myna +; length c. 27 cm. (10½ in.).

FIELD CHARACTERS. A small slim pinkish brown-and-grey dove. *Above*, head and neck lilac-pink with a miniature 'chessboard' in black and rufous on either side of foreneck; rest of upper plumage earthy brown with prominent grey patches on wing-shoulders. *Below*, breast pinkish brown; rest of underparts white. Tail graduated, with much white near tips of the outer feathers. Sexes alike.

154

COLUMBIFORMES

FIELD CHARACTERS. As for 537. A slender white-spotted pinkish grey and brown pigeon with a conspicuous black-and-white 'chessboard' on hindneck. See Key to the Subspecies, and Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Race peculiar to Ceylon. Abundant all over the island up to c. 1400 m. in the hills. Affects well-wooded country and paddyfields.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 537 q.v.

BREEDING. *Season* practically all year; chiefly from December to September (Phillips). *Nest and eggs* as in peninsular birds. Average size of 30 eggs 25.7 × 20.0 mm. (Baker).

MUSEUM DIAGNOSIS. Differs from the Indian *suratensis* (537) only in its smaller size.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	128-136	19-20	20-22	114-132 mm.
♀♀	130-136	19-20	20-22	118-127 mm. (HW)

COLOURS OF BARE PARTS. As in 537.

539. **Burmese Spotted Dove.** *Streptopelia chinensis tigrina* (Temminck)

Columba Tigrina Temminck, 1810, in Knip, Les Pigeons, les colombes: 94, pl. 43 (Timor and Batavia; type from Java)

Baker, FBI No. 1874, Vol. 5: 244

LOCAL NAMES. As under 537 where applicable.

SIZE. Pigeon —; slenderer. Length c. 30 cm. (12 in.).

FIELD CHARACTERS. As of 537. A slender white-spotted pinkish grey and brown pigeon with a conspicuous black-and-white 'chessboard' on hindneck. See Key to the Subspecies, and Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident: Cachar, Manipur, Mizo, and East Pakistan. A single doubtful old record from the Nicobars. Affects well-wooded moist deciduous biotope chiefly plains and foothills, keeping to paddyfields etc. like the other races.

Extralimital. 'Burma, [Thailand], Malay Peninsula, Indochinese countries, Palawan, Borneo, Sunda Is. from Sumatra to Babar. Introduced into Celebes, small islands in the Flores Sea, and the Moluccas' (Peters).

GENERAL HABITS, FOOD. As in 537.

VOICE and CALLS. Pattern of 'song' of Manipur birds recorded as consistently different from Indian — a syncopated *krük-kroo* minus the terminal *kroos* (SA).

BREEDING. *Season, nest, and eggs* as in the Indian race. Average size of 50 eggs 27.6 × 21.9 mm. (Baker).

MUSEUM DIAGNOSIS. Birds from Cachar, Manipur, etc. are intermediate between the Indian *suratensis* and the Burmese *tigrina*. The latter is distinguished by absence of rufous spots on back, whilst those on the wing-coverts, scapulars and tertiaries are obsolete or absent. Outer webs of median coverts pale vinous-brown; greater

COLUMBIFORMES

156

Young (immature) lacks the chessboards on foreneck. Plumage duller and browner overall; feathers of upperparts and wing-coverts edged with rufous; breast duller and less pink.

STATUS, DISTRIBUTION and HABITAT. Mainly resident, hitherto believed more or less sedentary. Evidently also migratory to an unsuspected extent, but movements as yet very unclear. Restricted to dry deciduous biotope, and largely coincident with Ring Dove (534); more common in semi-desert facies. Throughout West Pakistan and India (up to c. 1000 m. in the western Himalayas and 1500 m. in the peninsular hills) east to Bihar, W. Bengal and East Pakistan (Tippera), south through the Peninsula to Rameswaram I. and Kanyakumari. Not Nepal, Sikkim, Bhutan, Assam or Ceylon. Recorded in the Andaman Islands (Port Blair) c. 1898; possibly introduced. Not met by later observers, so evidently failed to establish in the palpably inappropriate moist biotope. Birds in Baluchistan and NW. frontier districts of W. Pakistan intergrade with the paler race *ermanni* (Bonaparte) of Turkestan etc. Affects village environs and stony scrub-and-bush country about cultivation, particularly where interspersed with *Euphorbia* hedges and *Opuntia* thickets.

MIGRATION. An example ringed on 15.iii.1961 near Bhuj in Kutch (c. 23°10'N., 69°50'E.) was recovered on 27.ii.1964 near Hyderabad in W. Pakistan (c. 25°20'N., 68°25'E.), c. 200 km. north of the ringing place. Previously Ticehurst had recorded with surprise 4 or 5 exhausted birds, obviously on migration, coming on board ship when c. 10 miles off Karachi on a foggy morning in late March 1918 (*Ibis* 1923: 466).

GENERAL HABITS. Similar to Indian Ring Dove (534). Keeps in pairs or small parties — sometimes large close-packed flocks of 50 or more — glean-ing with it and with other doves in stubble fields and village environs. Occasionally stretches up to pluck seeds from growing weeds 30 to 50 cm. high. Male has the characteristic bowing courtship display on the ground, advancing towards the female in stiff ludicrous hops punctuated by a couple of mincing steps — head lowered, throat inflated, rump arched and tail depressed — bobbing and cooing. Female, seemingly quite unimpressed, usually moves away from these amorous advances, *flying off* when too ardently pursued, but sometimes crouching to permit copulation. Also has the typical aerial display, launching upwards from an exposed perch with noisy flapping, and sailing down on motionless wings in an arc or wide spiral to another perch nearby.

FOOD. Grains of paddy, jowar, bajra and other cereals and lentils; grass- and weed seeds.

VOICE and CALLS. A soft, pleasant *coo-roo-coo-roo-coo* or *coo-do-do-do-do*.

BREEDING. *Season* not defined, practically all year, chiefly January to October; two or more broods raised. *Nest*, a ridiculously flimsy and sketchy platform of twigs and grass stems, placed low down in a *Euphorbia* or other open bush, or a stunted date palm (*Phoenix sylvestris*). Although in exposed situations, with the incubating bird sitting closely the nest is quite inconspicuous. Nests frequently built on cornices and rafters, or on a rolled-up chik, in inhabited dwellings unmindful of the close proximity and comings and goings of the human occupants. *Eggs*, almost invariably 2, white, elliptical, with a smooth texture. Average size of 60 eggs 25.3 × 19.3 mm.

PIGEONS, DOVES

157

(Baker). Both sexes share in building the nest, incubation, and tending the young; incubation period unrecorded.

MUSEUM DIAGNOSIS. The extralimital race *ermeni* (of Afghanistan and Turkestan) with which the West Pakistan population is intermediate, is slightly larger and markedly paler (Wing ♂♂ 135-145; ♀♀ 130-140 mm. — Hartert). It is likely that some of these birds may be found as winter visitors in NW. India.

Chick (in down) dull yellowish fawn coloured.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	121-137	17-19	18-22	107-119 mm.
♀♀	124-134	17-19	20-21	104-113 mm. (SA, HW).

Weight 30 ♂♂ 71-91 gm. (av. 80.4 gm.).—SA.

COLOURS OF BARE PARTS. Iris brown; eyelids pale magenta. Bill brownish black. Legs and feet magenta; claws brownish black.

Genus CHALCOPHAPS Gould

Chalcophaps Gould, 1843, Bds. Austr., pt. 13; pl. (8) (= 5, pl. 62 of bound vol.). Type, by monotypy, *Columba chrysoclerus* Wagler

Small, terrestrial-feeding, metallic-plumaged pigeons rather closely allied to *Caloenas* both in anatomy and the possession of 12 tail-feathers, but lacking the neck-hackles. Wing of moderate length: 2nd and 3rd primaries (as.) subequal. Tarsi and toes bare, the latter slender and well adapted for running about on the ground.

CHALCOPHAPS INDICA (Linnaeus)

Plate 49, fig. 9

LOCAL NAMES. *Rāj ghāhū* (Bengal); *Pāchu kārdā* (Marathi); *Ardi bellagurā* (Telugu); *Pāḍiki pūrā* (Tamil); *Ōmāra prāru*, *Mārikā prāru* (Malayalam); *Kār* (Lepcha); *Matī kupōku* (Assam); *Sil kopu* (Nowgong, Assam); *Dastulei* (Cachar).

SIZE. Myna +; length c. 27 cm. (10½ in.).

* Described as larger and darker (Wing ♂♂ 153-157) with abdomen paler than throat and breast, and green more pronounced in upperparts than metallic bronze. Race untenable.

PIGEONS, DOVES

159

normally 2 or 3 metres up in a dense bamboo clump or sapling in forest. Eggs, 2, pale creamy buff or *cafe-au-lait*, elliptical, smooth-textured. Average size of 200 eggs 27.0 × 21.0 mm. (Baker). Both sexes share in nest-building, incubation, and tending the young. Incubation period believed to be about 12 days, but needs confirming.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

Female like male but generally with less white on forehead and supercilia; grey crown and nape somewhat suffused with reddish. White patch on wing-shoulder and white barring on rump less pronounced. Central tail-feathers redder brown and only the outermost pair grey.

Young (immature) of both sexes like adult female but duller, the bronze-green of mantle less in extent and barred with copper-red. A broad dull green and rufous band across wing (median and lesser coverts); inner secondaries tipped with rufous-red. Underparts except for pale chin and throat uniform dull brown darker than in adult, the feathers faintly vermiculated and narrowly barred with dull black, especially on breast and flanks. Under tail-coverts black.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	147-156	22-26	25-29	93-100 mm.
♀♀	147-149	c. 22	24-26	89-91 mm. (SA)

Wing average 14 ♂♂ 149, 8 ♀♀ 143 mm. (HA).

Weight 8 ♂♂ 119-144 gm. (av. 132) — SA.

COLOURS OF BARE PARTS. Adult. Iris brown. Bill coral-red, magenta on cere. Legs and feet pinkish- or purplish red; claws brown. Immature. Iris brown; orbital skin slaty brown. Bill slaty brown with ivory tip; mouth pink. Legs and feet pinkish grey; claws horny brown.

543. Ceylon Emerald Dove. *Chalcophaps indica robinsoni* Baker

Chalcophaps indica robinsoni Baker, 1928, Bull. Brit. Orn. Cl. 48: 58

(Cocawatte Estate, Ceylon)

Baker, FBI No. 1853, Vol. 5: 217

LOCAL NAMES. *Nīl kobḍiyā* (Sinhala); *Pāḍhakai parā*, *Thamīl parā* (Tamil).

SIZE. Myna +; length c. 27 cm. (10½ in.).

FIELD CHARACTERS. As of 542. A small brownish pink forest dove with brilliant bronzed emerald-green mantle. See Key to the Subspecies, and Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Common resident. Race peculiar to Ceylon. Affects forests and well-wooded areas throughout the island, to over 1600 m. in the hills.

GENERAL HABITS. As of the Indian race (542) q.v. 'The highest elevations are visited only when *nīlā* [*Streblanthus* = *Kercia*] is seeding upcountry (about once in eleven years) when it migrates to exceptional heights to feast on the seeds' (Henry).

158

COLUMBIFORMES

FIELD CHARACTERS. A small brownish pink forest dove with brilliant bronzed emerald-green upperparts. Crown and neck grey, with prominent white forehead and eyebrows, and a band of white-fringed feathers across lower back. A white-bordered vinous-grey patch on wing-shoulder. Rump grey; tail brown and grey, with a broad black cross-band, broken in the middle. Sexes more or less alike, but see Museum Diagnosis.

× c. 1

Bronze-green mantle, white rump-patch, chestnut underwing, and coral red bill conspicuous in flying flash-past.

Superficially a more brilliant but passable facsimile of Green Imperial Pigeon (506).

STATUS, DISTRIBUTION and HABITAT. Resident (and sedentary as far as known) in evergreen and moist deciduous biotope, patchily throughout India up to c. 1800 m. in the lower Himalayas, from Kashmir (Jammu) east to NEFA and Assam (including Nepal, Sikkim, and Bhutan); East Pakistan. South through the entire Peninsula. Affects thick secondary and mixed bamboo jungle and outskirts of forest clearings, chiefly in foothills country.

Probability of some sort of migratory movement suggested by their attraction to incandescent lights during certain moonless overcast nights in the late monsoon months with heavy fog and ground mist. These doves along with several other belivedly sedentary diurnal species then obviously distracted from their course while actively on the move. (For details see Sálím Ali, 1962, JBNHS 59: 128-9.) Further investigation is desirable.

Extralimital. Burma, Malay Peninsula, Indochinese countries, Philippines, Indonesia.

GENERAL HABITS. A ground-feeding dove. Keeps singly or in pairs, but locally quite abundant. Usually seen running about gleaning on earth roads through forest and plantations, or on the sites of cartmen's bivouacs with scattered spillage from grain bags in transit, or leavings of bullock feed. Fond of overgrown outscoured ravines running through tea plantations etc., and tangles of wild castor plants (*Ricinus communis*) in old *jhoom* or cultivation clearings, for midday rest. Flight silent, very swift and direct but evidently lacking in quick manoeuvrability; hence the frequent casualties of birds dashing themselves to death against walls of plantation buildings as they shoot across at top speed through the surrounding glades low under the forest canopy.

FOOD. Grain, seeds, and fallen berries — those of lantana (*Lantana aculeata*) being a favourite. Termites caught on the ground (Baker).

VOICE and CALLS. A soft, deep, very low single moaning note *hoon*, with a nasal ending, repeated at intervals.

BREEDING. Season, variable locally, covering practically the whole year; in areas with a definite cold winter chiefly March to May; in Kerala peak periods April-May and again November-December. Nest, the typical flimsy twig structure of doves, perhaps somewhat more compact and better concealed;

COLUMBIFORMES

160

FOOD. Seeds and berries. Said to be very fond of seeds of the candlenut tree (*Sehium sebiferum*) and castor (*Ricinus communis*).

VOICE and CALLS. A mournful, somewhat ventriloquistic booming note, as of the Indian bird, ' *th-oon* . . . *th-oon*, uttered with crop inflated as in Pouter Pigeon' (Henry).

BREEDING. Season, practically all year but chiefly February-March and again in September. Nest and eggs as in 542. Nest sometimes placed on a cardamom or tree-fern frond in jungle. Average size of 24 eggs 25.9 × 20.8 mm. (Baker).

MUSEUM DIAGNOSIS. Differs from peninsular birds both in colour and size. Adult male has the grey of head and neck running down to the scapulars in a well-defined line. Abdomen in both sexes lighter coloured than throat and breast, a difference hardly perceptible in Indian birds.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	135-147	21-22	c. 24	— mm.
♀♀	130-142	19-21	22-24	80-93 mm. (HW)

COLOURS OF BARE PARTS. As in 542.

544. Andaman Emerald Dove. *Chalcophaps indica maxima* Hartert

Chalcophaps indica maxima Hartert, 1931, Orn. Monatsb. 39: 145

(Golapabung, South Andamans)

Not in Baker, FBI

LOCAL NAMES. Unrecorded.

SIZE. Myna +; length c. 27 cm. (10½ in.).

FIELD CHARACTERS. As of 542. A small brownish pink forest dove with brilliant metallic emerald-green mantle. See Key to the Subspecies, and Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Race peculiar to the Andaman Islands. Common resident in appropriate forest biotope everywhere.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 542.

BREEDING. Season, undefined as in other races: a fresh egg taken on 29 May (Osmaston, 1906, JBNHS 17: 489) and specimens with mature gonads procured on 16 February (Abdulali, 1964, *ibid.*, 61: 528). Nest and eggs as in Indian birds.

MUSEUM DIAGNOSIS. Differs from nominate *indica* of peninsular India and Burma only in having a larger wing.

MEASUREMENTS

Wing 12 ♂♂ 145-155 (av. 151), 6 ♀♀ 142-162 (av. 149) mm. — HA.

Hartert gives Wing 3 ♂♂ 157-164; 1 ♀ 165 mm.

COLOURS OF BARE PARTS. As in 542.

544a. **Nicobar Emerald Dove.** *Chalcophaps indica augusta* Bonaparte
See Appendix

Genus **CALOENAS** G. R. Gray

Caloenas G. R. Gray, 1840, List Gen. Bds.: 59. Type, by original designation, *Caloenas nicobarica* (Gmelin) = *Columba nicobarica* Linnaeus
Cf. Salvadori, 1893, Cat. Bds. Brit. Mus. 21: 614-18

Distinguished from all other pigeons by its long metallic neck hackles, longest and narrow on hindneck, disintegrated and hair-like on occiput and foreneck. Legs long and stout; toes slender, well adapted for walking. Bill large with the apical portion curved; a fleshy protuberance at base of culmen, larger in male than in female. Tail of 12 feathers.

544b. **Nicobar Pigeon.** *Caloenas nicobarica nicobarica* (Linnaeus)

Columba nicobarica Linnaeus, 1758, Syst. Nat., ed. 10, 1: 164 (Nicobar Islands)
Baker, FBI No. 1851, Vol. 5: 213
Plate 49, fig. 7

LOCAL NAME. *Lo-wag* (Nicobars).

SIZE. Pigeon \pm ; length c. 41 cm. (16 in.).

FIELD CHARACTERS. A dark slaty grey pigeon with lustrous metallic blue-green and copper-bronze upperparts; unmistakable by the glistening mane-like neck hackles and sharply contrasting white tail-coverts and tail.

$\times c. \frac{1}{2}$

Female very similar to male but with head, neck and breast more greyish slaty; sheen on upperparts less deep blue; neck hackles shorter.

Young (immature) duller coloured, lacking the neck hackles, and with bronzy green tail instead of white.

STATUS, DISTRIBUTION and HABITAT. Resident, common and locally abundant in the Nicobar Islands (Car Nicobar, Batti Malv, Tillanchang, Teresa, Camorta, Nancowry, and others). Perhaps less rare and straggling

PARROTS

163

Order PSITTACIFORMES

Family PSITTACIDAE: Parrots

Contains arboreal fruit- and grain-eating birds usually of brightly coloured plumage, all the Indian representatives being chiefly green. Bill short, stout, strongly hooked: upper mandible loosely articulated with the skull and capable of kinetic movement. Tongue thick and fleshy. Feet zygodactylous — 2 toes in front, 2 behind — adapted for clambering among branches. Feathers furnished with an aftershaft. Primaries 10; tail-feathers 12 in both Indian genera. For general information see Jean Dorst, 1964, Article 'Parrot' in Thomson, A. L. (ed.) *New Dict. Birds*: 600-602; for morphological details Stresemann, E., 1927-34, *Ates*: 820-4; Baker, 1927, FBI 4: 196; Van Tyne, J. & Berger, A. J., 1959: 455.

Genus PSITTACULA Cuvier

Psittacula Cuvier, 1800, Leçons d'Anat. Comp. 1, table at end. Type, by subsequent designation, *Psittacus alexandri* Linnaeus. (Mathews, 1917, Bds. Austr. 6: 169)

Tail very long and graduated, the median feathers narrow, pointed, and much exceeding the others in length. Bill thick, deeper than long: upper mandible swollen at the sides, culmen convex, much curved; lower mandible short and blunt.

The genus contains some of the most abundant and destructive bird pests of agriculture and horticulture in India.

COLUMBIFORMES

in the Andamans than supposed. Has been collected and/or observed (in some cases breeding) as far north as the Cocos (Barren I., Havelock I., S. Sentinel, S. Andaman, and doubtless occurs on others of the group). Affects heavy evergreen forest, chiefly on small uninhabited islets off the larger land masses.

Extralimital. Mergui Archipelago eastward through the Indonesian, Philippine and other islands over the greater part of the Indo-Australasian region.

GENERAL HABITS. Keeps singly, in parties of 3 or 4, and flocks of a dozen to 20 or 30. Feeds entirely on the ground, walking about briskly hither and thither with a steady sprightly gait flicking aside the leaves to expose fallen seeds and berries, or pecking in the mulch with its bill. Walks very much like Emerald Dove but with wings drooping low at the sides, giving the impression of being maimed in the shoulders. Flight looks rather heavy, but in fact is swift and powerful, capable of being sustained over long distances when traversing wide stretches of sea from one island to another in search of food. A flock in swift commuting flight high up in the air is reminiscent of sandgrouse (Hume). Launches from tree and flushes from ground with a characteristic very noisy flutter of wings often sufficiently diagnostic even when the bird itself unseen. When settling, pitches clumsily on to a horizontal bough high up in the foliage canopy, often walking along it like a hen.

FOOD. Fleshy fruit picked off the forest floor, and seeds including some very hard ones like plum stones, evidently for crushing which the stomach is specially adapted (for structural details see Flower, 1860, *Proc. zool. Soc. London*: 330).

VOICE and CALLS. Normally very silent. Occasionally utters a harsh guttural croak not unlike that sometimes made by a domestic pigeon when handled (Butler).

BREEDING. *Season.* January to March-April; presumably, as in most pigeons, also at other times. *Nest.* an untidy loosely put-together platform of twigs built c. 3 to 8 metres up in trees in evergreen forest; often several nests thickly in a single tree in rookery fashion. In the 1870s W. Davison found it breeding 'in thousands' on Batti Malv island, almost every bushy tree containing several nests. *Egg.* a singleton, white, smooth-textured, long ellipse, often slightly pointed at either end. 'Colour of the membrane lining the shell gives a delicate purple tinge to the egg' (Osmaston). Average size of 18 eggs 48.0 \times 33.9 mm. (Baker). Both sexes incubate (in captivity) and tend the young. Incubation period unrecorded.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus
σ^7 φ	247-268	c. 24-27	c. 36-42 mm. (Baker)

An adult σ^7 recently collected has wing 240 mm. (Abdulali).

Weight 2 σ^7 460, 525; 4 φ 490-600 gm. (Grubb).

COLOURS OF BARE PARTS. Iris white, buff, or nut-brown [age?]. Bill greyish or slaty black. Legs and feet purplish violet to almost coral-red.

545. **Large Indian Parakeet.** *Psittacula eupatria nipalensis* (Hodgson)

Palaeornis Nipalensis Hodgson, 1836, *Asiat. Res.* 19 (1): 177 (Nepal)

P. (alcecorus) indoburmanicus Hume, 1878, *Stray Feathers* 7: 459 (No locality; restricted to Sikkim by Kloss)

Baker, FBI Nos. 1497, 1498, Vol. 4: 199, 200

LOCAL NAMES. *Rāi lōā*, *Hirēmān lōā* (Hindi); *Pāhārī Lōā* (U.P., Lucknow); *Kārdān lōā* (M.P., Saugor); *Tekru* (= 'of the hills', Sukkur, Sind); *Chandras* (Bengal); *Kārdān sōā*, *Kārdān* (Nepal); *Ni to* (Lepcha); *Sōā* or *Sōā* (Orissa).

SIZE. Pigeon \pm ; slenderer. Length σ^7 (including long pointed tail) c. 53 cm. (21 in.); φ somewhat smaller.

FIELD CHARACTERS. A large grass-green parakeet with the typical short massive, deeply hooked red bill, and a conspicuous deep red patch on the wing-shoulders (secondary wing-coverts).

Male (adult) has a prominent rose-pink collar round the back and sides of neck, and a broad black band from the lower mandible to the rose collar. Tail-feathers below dull yellow.

Female and Young (immature) lack the rose-pink collar and the black mandibular stripe.

PARROTS

165

STATUS, DISTRIBUTION and HABITAT. Resident; also nomadic and locally migratory — the movements dependent chiefly on food supply. West Pakistan (Sind, chiefly the northern and southern parts; Bahawalpur; Peshawar district), and all India from Punjab along the Himalayan foothills (recorded up to c. 1600 m.), bhabar, terai, and duars (including Nepal, Sikkim and Bhutan) across the Gangetic Plain to eastern Assam and NEFA; Nagaland and Manipur (subspecies? See under 547). East Pakistan (Dacca, Chittagong, Tippera, etc.) south through Gujarat, N. Andhra, Madhya Pradesh and Orissa roughly to about latitude 18°N.; plains and hills normally to c. 800 metres. Affects dry and moist deciduous biotope — forest and well-wooded country. Also the older canal-irrigated desert settlements with well-grown trees and forest plantations, e.g. in the Punjab.

GENERAL HABITS. Keeps in parties of 3 or 4 birds or small flocks which band together in large congregations where food is abundant. Has noisy communal roosts, usually, unshared with other species, in large densely foliated trees and groves in forest at which the birds collect from all quarters at sunset flying over long distances in batches of 5 to 50. Flight graceful and swift in spite of the seemingly 'stately' and unhurried wing-beats — reminiscent of the Naktas as compared with the smaller ducks. Flocks do considerable damage in orchards, the birds clambering amongst the branches and gnawing into the half-ripe fruit while still on the tree or plucking and flying off with it to a convenient perch, there raising it up to the bill held in one foot; often wastefully abandoning it after a bite or two and returning to filch more. Highly destructive also to ripening cereal crops, cutting off the growing ears, wantonly pulling them to shreds and wasting far more grain than it actually consumes.

FOOD. Fruits, vegetables and seeds of all kinds, wild or cultivated; also cereals like maize, wheat, and paddy. Analyses of stomach contents in an agricultural area in Lyallpur (W. Pakistan) showed 52 per cent crop seeds, 2.7 per cent weed seeds, 11.4 per cent neutral seeds, 4.8 per cent vegetables, 19.3 per cent cultivated fruits, 9.80 per cent wild fruits (Husain & Bhalla, 1937). Thus the bird is harmful in the highest degree to agriculture and horticulture. Like other parakeets feeds avidly also on the nectar of *Salmalia*, *Butea*, *Erythrina*, and suchlike flowers, but biting off and discarding (sometimes eating) the petals and floral parts to reach the liquid, thus evidently not even useful in cross-pollinating.

VOICE and CALLS. A loud, high-pitched screaming single note *keeek*, or *kee-arr*, deeper and more sonorous than of the commoner Roseringed species; uttered from a perch as well as on the wing. In captivity readily learns to imitate a few words of human speech, but not known to mimic any extra-specific calls or sounds in the wild state.

BREEDING. Season, overall December to April, generally somewhat earlier than the Roseringed Parakeet. Nest, a vertical shaft a few cm. deep with a neat round entrance-hole, cut by the birds themselves in the trunk of a coconut palm or large softwood tree such as *Salmalia malabarica*; occasionally also in sal (*Shorea robusta*), sheesham (*Dalbergia sissoo*) and other hardwoods growing in rambling gardens or in forest. In the Sunderbans the mangroves Keora (*Sonneratia apetala*) and Sundri (*Heritiera minor*) are

PARROTS

167

SIZE. Pigeon \pm ; slenderer. Length σ (including long pointed tail) c. 51 cm. (20 in.); φ somewhat smaller.

FIELD CHARACTERS. A large grass-green parakeet with the typical short massive, deeply hooked red bill, and a conspicuous deep red patch on wing-shoulders (secondary wing-coverts). Indistinguishable from 545 except in the hand (see Museum Diagnosis).

STATUS, DISTRIBUTION and HABITAT. Resident, with nomadic and local migratory movements governed mainly by food supply; patchily throughout peninsular India roughly south of 18°N. latitude, and Ceylon (low-country Dry zone). Affects forest and well-wooded country to c. 900 metres elevation, in dry- and moist-deciduous biotope.

GENERAL HABITS, FOOD, VOICE and CALLS. As in the northern race 545, q.v. In season the fleshy petals of *mhowa* flowers (*Bassia latifolia*) comprise a favourite food item.

BREEDING. Season, both in peninsular India and Ceylon chiefly November December to March/April. Nest and eggs as in 545, the latter somewhat smaller. Ceylon eggs measure c. 31 \times 24 mm.

MUSEUM DIAGNOSIS. Slightly smaller and less richly grass-green than *nipalensis*. Bill less massive (greatest height c. 20.21 mm. f. 22-24). Black mandibular stripe narrower. For details of plumage see Baker, loc. cit.

MEASUREMENTS

Size decreases clinally southward; Ceylon birds measure			
Wing	Bill (from posterior edge of cere)	Tarsus	Tail
$\sigma\sigma$ 187-219	32-36	c. 20	200-304 mm. (HW, CBT)
$\varphi\varphi$ 175-195 (Baker)			

COLOURS OF BARE PARTS. 'Iris pale blue speckled with yellow, pale yellow, or yellow with a blue outer ring. Bill deep red. Feet plumbeous or greenish slate' (Baker).

547. Large Burmese Parakeet. *Psittacula eupatria acensis* (Kloss)

Palaeornis eupatria acensis Kloss, 1917, Jour. Nat. Hist. Siam 2: 219

(Bhamo, Upper Burma)

Baker, FBI No. 1498 (part), Vol. 4: 200 = *indoburmanica*

LOCAL NAMES. Unrecorded.

SIZE. As of 545: pigeon \pm ; slenderer, with long pointed tail.

FIELD CHARACTERS. A large grass-green parakeet with long pointed tail and a bright red shoulder-patch. Indistinguishable in the field from 545 or 548 qq.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident, with local movements as in 545. Cachar ('very common'); presumably also Nagaland and Manipur, but western limits of this form not yet worked out.

Extremities. Burma south to Amherst (to c. 16°N. lat.).

166

PSITTACIFORMES

specially favoured. Holes — sometimes several in the same trunk in apartment-house fashion — unlined, but may have a bed of wood shavings fortuitously accumulated at the bottom during excavation. Nest-holes of barbets and woodpeckers are often enlarged and appropriated. Normally nests away from populated human settlements and only exceptionally in holes in buildings etc., as is so common with Roseringed. Eggs, 3 or 4, white, glossless, roundish ovals. Size c. 34 \times 28 mm. Both sexes partake in excavating the nest, incubation, and feeding the young by regurgitation. Incubation period 19-21 days (Baker). Courtship display not specifically described but presumably of same ludicrous pattern as in Roseringed (550), q.v.

MUSEUM DIAGNOSIS. Distinguished from the nominate race (546) of peninsular India and Ceylon by somewhat larger size, brighter coloration, and more massive bill. Black mandibular stripe much broader and more conspicuous; occiput, cheeks, and nape usually more washed with blue.

MEASUREMENTS

	Wing	Bill (from posterior edge of cere)	Tarsus	Tail
$\sigma\sigma$ 200-234		33-40	19-22	220-361 mm.
$\varphi\varphi$ 192-221		33-36	19-22	206-325 mm. (SA)
Ticehurst (<i>Ibis</i> 1923: 43) gives for birds from N. India to Madhya Pradesh				
$\sigma\sigma$ 225-236		36-38	—	— mm.

Greatest height of bill 22-24 mm.

COLOURS OF BARE PARTS. Iris lemon-yellow with a narrow outer blue ring; eyelids orange-yellow. Bill scarlet, darker on culmen orange-red at tips. Legs and feet dirty yellow; claws slaty.

MISCELLANEOUS. Learns to imitate a few words but is a far less accomplished mimic than the Hill Myna. Along with the Roseringed Parakeet is taught to perform a variety of clever table-top tricks such as loading and firing a toy cannon, and performing parakeets usually form a popular side-show at upcountry *melas* and fairs. Very popular as the 'common man's' pet, vast numbers of partly fledged young being regularly taken from nests for sale in bird markets, or hawked in the streets of most Indian towns; usually hung imprisoned in tiny hoop-iron cages outside bazaar shops. Birds from certain areas (e.g. Amrabad Plateau in Andhra and Dumkhal in Rajpipla, Gujarat) have acquired a local reputation for special excellence as talkers, and are highly prized by fanciers.

546. Large Ceylonese Parakeet. *Psittacula eupatria eupatria* (Linnæus)

Psittacus Eupatria Linnæus, 1766, Syst. Nat., ed. 12, 1: 140

(No locality = Gingi, India ex Brisson)

Baker, FBI No. 1496, Vol. 4: 198

Plate 50, fig. 3

LOCAL NAMES. *Hirēmān tīlā* (Hindi); *Pedda chilukā*, *Bandi rama chiluka* (Telugu); *Periya kili* (Tamil); *Laba giravā* (Sinhala).

168

PSITTACIFORMES

GENERAL HABITS, FOOD, VOICE and CALLS. As in the other races, cf. 545.

BREEDING. Season, chiefly December to February/March. Nest and eggs as in 545; size c. 34 \times 28 mm.

MUSEUM DIAGNOSIS. Closely resembles *P. e. magnirostris* (548) of the Andamans, but has a smaller bill and perhaps a yellower throat, while it lacks the narrow sky-blue neck-ring of that race (C. Boden Kloss).

MEASUREMENTS of the type specimen, σ adult: Wing 217; 'culmen' 38 (greatest height 22); tarsus 21; tail 342 mm.

COLOURS OF BARE PARTS. Iris 'white bluish speckled' (Anderson). Rest as in 545.

548. Large Andaman Parakeet. *Psittacula eupatria magnirostris* (Ball)

Palaeornis magnirostris Ball, 1872, Jour. Asiat. Soc. Bengal 41 (2): 278

(Andaman Islands)

Baker, FBI No. 1499, Vol. 4: 201

LOCAL NAMES. None recorded.

SIZE. As of 545: pigeon \pm ; slenderer, with long pointed tail.

FIELD CHARACTERS. A large grass-green parakeet with long, pointed tail and a bright red shoulder-patch. Indistinguishable in the field from the other races, qq.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Race peculiar to the Andaman Islands. Common and fairly plentiful everywhere in the North, Middle, and South Andamans, moving about between the smaller islands of the group in search of food. Has been specifically recorded on Table, Long, Barren, and South Sentinel islands besides the main ones, but is doubtless found on most others ecologically suitable. Also occurs on Coco Is. and Narcondam. Not reported south of the Ten Degree Channel — in the Nicobar Group. Affects tall evergreen forest and mangroves.

GENERAL HABITS. Keeps in noisy parties and flocks of half a dozen to several score to the lofty forest trees, joining up into enormous congregations at roosts which are often shared with the Redbreasted species (552). The birds commonly roost among mangroves (*Rhizophora mucronata*) growing along tidal creeks, preferably such patches as are more or less islanded from the shore by shallow water. Large areas of such mangroves become denuded ('stag-headed') at the top, the branches presenting a dead appearance due to the stripping of the leaves by the myriads of parakeets that sleep in them.

FOOD. As in the other races — fruits, grain, buds, seeds both wild and cultivated.

VOICE and CALLS. Loud harsh screeching screams as typical of the parakeets (cf. 545), but the notes said by W. Davison to be very distinct from either the Redchecked or Redbreasted species occurring side by side with it.

BREEDING. Season, February-March. Nest, a self-cut hole high up in the trunk of a lofty tree, usually on the edge of forest. Osmaston found one nest 150 feet up, and another over 100 feet, in immense jungle trees. The latter nest was more than 8 feet below the entrance-hole. Eggs, 2 or 3, white. Average size of 10 eggs 35.1 \times 28.2 mm. (Baker).

PARROTS

169

MUSEUM DIAGNOSIS. Distinguished from all other races by its heavier, more massive bill; from *nipalensis* by the well-developed narrow, almost sky-blue ring above the rosy hind-collar. Red shoulder-patches much brighter.

MEASUREMENTS		Wing	Bill (from cere)
♂♂	205-217		39-45 mm.
♀♀	190-209		34-39 mm.
			(Baker)

Weight 2 ♀♀ 220, 225 gm. (Grubb).
COLOURS OF BARE PARTS. As in 545.

PSITTACULA KRAMERI (Scopoli)	
Key to the Subspecies	
(Males only)	
Lower mandible black.....	<i>P. k. manillensis</i>
Lower mandible red.....	<i>P. k. borealis</i>

549. Northern Roseringed Parakeet. *Psittacula krameri borealis* (Neumann)

Palaeornis krameri borealis Neumann, 1915, Orn. Monatsb. 23: 178 (Assam)
Psittacula krameri fragosa Koelz, 1954, Contrib. Inst. Regional Exploration, No. 1: 25 (Anadra, Sirohi, Rajasthan)
Baker, FBI No. 1501, Vol. 4: 204

LOCAL NAMES. *Tōtā*, *Lybār tōtā* (Hindi); *Gallar* (NW. Pakistan); *Chātūn* (Sind); *Tiyā*, *Tiyā tōtā* (Bengal); *Tenthia sūga* (Nepal); *Tōtā sōrāi* (Assam); *Daobator* (Cachari); *Pōpāt*, *Sūdo* (Gujarat); *Pōpāt*, *Kerā* (Marathi).

SIZE. Myna +; with long, pointed tail. Length overall c. 42 cm. (16½ in.).

FIELD CHARACTERS. A slim grass-green parakeet with the typical short, heavy, deeply hooked red bill.

Male with a rose-pink and black collar; no red shoulder-patch as in 545.

Female without the collar but with an indistinct emerald-green ring round neck.

Young (immature) like female. Male acquires pink-and-black collar in the third year.

STATUS, DISTRIBUTION AND HABITAT. Resident. West Pakistan (Baluchistan, Sind, NW. frontier districts, Punjab), and all northern India, eastward along the Himalayan foothills, terai, and the entire Gāngetic Plain through Assam and E. Pakistan, south to the arbitrarily fixed boundary of 20°N. lat.; Nepal, terai and bhabar. Affects moist- and dry-deciduous biotope—even semi-desert—keeping to light secondary jungle, gardens, orchards and cultivation in the neighbourhood of human habitations. Was introduced in the Andamans by Col. Tytler, about a hundred years ago (Hume, 1874, SF 2: 177) but failed to 'take off'.

Extralimital. Burma (including Shan States), SE. China, and reportedly Vietnam.

GENERAL HABITS. One of the most destructive bird pests of agriculture and horticulture. Keeps in small parties or large noisy rabbles which often

PARROTS

171

in rock scarps and walls of ruined buildings and ancient forts are freely occupied, many pairs often nesting close to each other in a loose colony. Frequently holes in the outside walls of buildings in towns are appropriated, often in the heart of noisy congested bazaars. Eggs, 3 or 4, sometimes 5, rarely 6; pure white roundish ovals. Average size of 20 eggs 29.3 × 24.0 mm. (Baker). Cutting of nest-hole by both sexes; incubation entirely by female. Period of incubation undetermined. Both parents feed the nestlings by regurgitation. According to Malcolm Macdonald, young leave nest about four weeks from laying of the egg by parent.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit. *P. k. borealis* differs from the peninsular and Ceylon race *manillensis* in being clinally larger and slightly paler and yellower; also in having—in the majority of cases—both mandibles red; in *manillensis* the lower mandible is black.

Weight 5 ♂♂ (104)	116-139 gm. (SA).				

COLOURS OF BARE PARTS. Iris yellowish white. Bill, both mandibles coral-red. Legs and feet greenish slate.

550. Roseringed Parakeet. *Psittacula krameri manillensis* (Bechstein)

Psittacus Manillensis Bechstein, 1800, Stubenvögel, 2nd Gotha ed.: 612 (Philippines, *error* = Ceylon)
Baker, FBI No. 1500, Vol. 4: 202
Plate 50, fig. 9

LOCAL NAMES. *Tōtā*, *Lybār tōtā* (Hindi); *Suā*, *Sūwā* (E. Madhya Pradesh); *Pōpāt*, *Sūdo* (Gujarat); *Pōpāt*, *Kerā* (Marathi); *Chilukā* (Telugu); *Kili* (Tamil); *Ransā giravā* (Sinhala); *Taitā*, *Modirattatā* (Malayalam).

SIZE. Myna +; with long pointed tail. Length overall c. 42 cm. (16½ in.).

FIELD CHARACTERS. A slim, grass-green parakeet with the typical short, heavy, deeply hooked red bill. Indistinguishable in the field from 549 q.v. except by black (v. red) lower mandible.

STATUS, DISTRIBUTION AND HABITAT. Resident. Peninsular India south of lat. 20°N. — the arbitrarily fixed boundary with the northern race — and Ceylon (low-country Wet and Dry zones). Affects moist- and dry-deciduous biotope: lightly wooded country and cultivation in the neighbourhood of human habitations.

1 In some cases lower mandible partly red partly black.

PSITTACIFORMES

170

band together in enormous swarms to raid ripening crops of jowar, maize, and other cereals, and orchard fruit. The birds clamber about among the twigs and gnaw into the half-ripe fruits, one after another, wasting far more than they actually eat. Or they descend in swarms upon ripening fields of food crops, biting into the ears of grain or cutting off the head completely and flying with it to a nearby tree where it is raised up to the bill with one foot and after a nibble or two wastefully discarded, the bird soon returning to the field to renew its ravages. Frantic shouts and stones hurled from slings by the ryot from his machan amidfield only serve to move the destructive horde to a different corner of the field where the depredation complacently continues. Rabbles of these parakeets commonly gather at wayside railway stations and goods sheds, clambering amongst the sacks of grain and groundnuts awaiting entrainment, biting through the fabric and helping themselves to the contents; or they waddle about comically on the ground with partly raised tail to pick up the spillage. Has communal roosts, often shared with crows and mynas, among groves of trees in sprawling urban gardens and outskirts of habitation where enormous numbers collect at sunset, flying in; battalion after battalion, from all points of the compass. The birds are extraordinarily abundant in and around some of the larger northern cities like Lahore, New Delhi and Kanpur. Flight swift and direct with rapid wing-beats.

A large noisy swearing mob of parakeets soon musters at the summons of a pair whose nest is threatened, e.g. by mynas or a snake, the birds flying at and around the intruder, flitting angrily about him in a sort of hypnotized frenzy, all screeching and screaming wildly together. The male has a very ludicrous courtship display, sidling up to his mate, stretching himself up to his full height, feeding her on regurgitated pap and caressing her, often with the bills interlocked. He suddenly backs away stiffly, eying her from a foot's distance with his head pulled well back (as if in rapt admiration), strutting and posturing, wings partially open at the shoulders, and the foot on her side lifted and ridiculously 'clawing the air' towards her. He then crosses over to the other side of the hen to repeat the antics, and thus back and forth several times. (For further details of courtship and mating see Sālim Ali, 1927, JBNHS 32: 218-19; also Malcolm Macdonald, 1960, *Birds in my Indian Garden*: 48-60.)

FOOD. Fruits, cereal, grain, and seeds of all kinds, wild as well as cultivated. Among items specifically identified are chillies (*Capsicum*), groundnuts (*Arachis hypogaea*), gram (*Cicer arietinum*); flower-petals and nectar of *Salvia miltiorrhiza*, *Erythrina indica*, *Butea monosperma*, *Bassia latifolia* and other species; seeds of *Prosopis spiciogera*, *Acacia arabica*, *Caruarina equisetifolia*, green spiny fruit of the common wasteland weed *Xanthium*, and flowers and fruits of *Capparis aphylla*.

VOICE AND CALLS. A loud, shrill screaming *kee-āk*, sometimes quickly repeated several times, varying in tempo with the occasion, and uttered at rest as well as on the wing.

BREEDING. Season, chiefly January to April but may go on till July. Nest, an unlined hollow in a tree-trunk, usually some small natural hole cut and enlarged by the birds to size; or preferably a readymade nest-hole of barbet or woodpecker, at any height between c. 3 and 10 metres. Holes

PSITTACIFORMES

172

GENERAL HABITS. As of the northern form (549), q.v. By its ubiquitous abundance, the vast swarms in which it occurs in agricultural areas, and its wasteful feeding habits, is a menace to food crops and orchard fruit. A highly destructive pest with no compensating virtues from the economic point of view. A popular pet of the 'common man'. If taken as nestling and hand-reared learns to repeat a few words rather indistinctly, and to perform a variety of table-top tricks.

FOOD, VOICE AND CALLS. As in 549. Locally very destructive to coffee 'cherries' in Mysore plantations.

BREEDING. Season overall (including Ceylon) chiefly between January and April/May. Nest, eggs and site as in the northern race. Average size of 100 eggs 30.5 × 24.3 mm. (Baker).

MUSEUM DIAGNOSIS. Clinically somewhat smaller than 549; differentiated from it chiefly by the lower mandible being black (v. red). Specimens from around lat. 20°N. are intermediate in this regard and can readily pass for either form. Ceylon birds agree with those from S. India in size and colour and cannot be separated from them.

PSITTACULA ALEXANDRI (Linnaeus)

Key to the Subspecies

Paler above and below; tail longer: ♂ 196-198, ♀ 172-193 mm.	<i>P. a. abbotti</i>
Darker above and below; tail shorter: ♂ 168-189, ♀ 145-171 mm.	<i>P. a. fasciata</i>

551. Indian Redbreasted Parakeet. *Psittacula alexandri fasciata* (P. L. S. Müller)

Psittacus fasciatus P. L. S. Müller, 1776, *Natursyst.*, Suppl.: 74 (Pondicherry, *error*, restricted to Arakan¹ by Ticehurst, 1933, Jour. Bom. nat. Hist. Soc. 36: 934)
Baker, FBI No. 1508, Vol. 4: 210
Plate 50, fig. 11

LOCAL NAMES. *Mādnā*, *Kājilā*, *Gour tōtā* (Hindi); *Imri bhilā* (Nepal); *Daobator gejaō* (Cachari).

SIZE. Pigeon —; with long, pointed tail. Length overall c. 38 cm. (15 in.).

FIELD CHARACTERS. A long and pointed-tailed grass-green parakeet with greyish pink head and plum-red throat and breast. A prominent yellow shoulder-patch where maroon in Alexandrine Parakeet (545).

1 But see remarks on allocation of type locality, Birwās, 1960, JBNHS 57: 536-7.

PARROTS

173

Male (adult). *Above*, head purplish grey with narrow black forehead running back to eyes, and broad black stripes from lower mandible to sides of head. Hindneck and sides of neck brighter green than rest of upperparts. A large yellow patch on wing-shoulder (median and greater coverts). *Below*, throat and breast vinaceous red; belly bluish green; vent and under tail-coverts yellowish green. Tail bluish green above with yellowish tips; dusky yellow below. Bill largely red.

Female. Head tinged blue-green and with less plum-coloured bloom; breast redder and darker, untinged with plum colour. Bill largely black.

Young (immature). Green throughout lacking the red breast and with only a slight dull brownish plum-colour about the head. Black head markings are acquired after the first moult (Baker). Bill like female's, but nestlings said to have both mandibles horny reddish orange. Needs confirmation.

STATUS, DISTRIBUTION and HABITAT. Resident, with local nomadic movements governed by food supply. The lower Himalayas (terai, bhavar, and up to c. 1500 m.) from about Dehra Dun (Kumaon) eastward through Nepal, Sikkim, Bhutan, and NEFA; south through Assam, Nagaland, Manipur, and Mizo (?). East Pakistan. Affects moist-deciduous biotope — thin secondary jungle and the neighbourhood of *jhoom* or shifting hill cultivation. Avoids dense evergreen forest.

Extralimital. SW. Yunnan, Burma, N. Vietnam and the other Indochinese countries; S. China and Hainan Island.

GENERAL HABITS. Usually keeps in parties of 6 to 10, occasionally larger flocks as when raiding fields of hill paddy or orchards. Often descends to the ground in harvested fields, parties of the birds waddling about actively to glean the fallen grain. Small flocks do the rounds of particular fruiting or flowering trees day after day until a tree is cleared. The birds feed quietly among the foliage as they clamber about, their presence in a tree only betrayed by the rain of leaves and other matter dropped in the process or by the muffled whirr of wings as a bird flies from one branch to another. When moving to another tree the flock fly swiftly as a compact wheeling battalion, uttering their distinctive cries. 'If one of a flock should happen to be wounded, its calling will bring the whole party flying round almost within arm's length, the entire number keeping up all the time an unceasing din of not unpleasant chatter' (Armstrong, 1876, SF 4: 308).

FOOD. Wild figs (*Ficus* spp.) and other wild and orchard fruit; leaf buds, and fleshy petals and nectar of *Salmaia*, *Butea*, and suchlike flowers; hill paddy, maize, etc.

VOICE and CALLS. A short sharp nasal, not unpleasant-scream, *kink*, quickly repeated by several birds together when a flock is disturbed and flying off; cry arrestingly different from that of Roseringed or Alexandrine.

BREEDING. *Season*, chiefly between January and April, varying locally with altitude and other conditions. *Nest*, a natural tree-hole enlarged and excavated by the birds to suit; normally c. 3 to 10 metres up in thin forest or well-wooded country, often close to cultivation and habitations; sometimes several nests in neighbouring trees in a loose colony. Nest-holes of barbets and woodpeckers frequently utilized. *Eggs*, 3 or 4, white, less spherical than of most parakeets. Average size of 50 eggs 30.9 × 25.6 mm.

PARROTS

175

553. Blyth's Nicobar Parakeet. *Prittacula caniceps* (Blyth)

Palaermis caniceps Blyth, 1846, Jour. Asiat. Soc. Bengal 15: 23 (Nicobars)

Baker, FBI No. 1509, Vol. 4: 212

Plate 50, fig. 1

LOCAL NAMES. None recorded.

SIZE. Pigeon ±, slenderer and with long, pointed tail. Length overall c. 61 cm. (24 in.).

FIELD CHARACTERS. A large, rather dingy-looking, long-tailed grass-green parakeet with black head markings similar in pattern to Redbreasted, but without the red breast.

Male (adult). *Above*, forehead black continued backward as a broad stripe to each eye; a very wide black band from lower mandible to each side of neck. Rest of head, hindneck and sides of neck brownish grey gradually diffusing into the bright yellowish green upperparts. Tail dingy yellow; middle feathers blue at base, violet-grey towards tips. *Below*, chin black; rest of underparts yellowish green like back. Bill red.

Female has the grey of the head tinged with bluish, and black bill.

STATUS, DISTRIBUTION and HABITAT. Resident. Nicobar Islands; so far recorded only on Great Nicobar, Montschall and Kondul. Affects high forest.

GENERAL HABITS. Keeps singly or in pairs or parties of 5 or 6, much to the tops of high trees when not feeding. Difficult to observe among the dense foliage, its presence only betrayed by its distinctive noisy calls which can be heard a long way off (Davison).

FOOD. Largely 'the ripe fruit of the pandanus, so abundant on the inhabited islands of the Nicobar group'.

VOICE and CALLS. 'A wild screeching note (but quite unlike either *magnirostris*, *erythrogenys* or *fasciatus*)'; continually uttered while at rest and in flight. A loud raucous *kraan kraan*, not unlike a crow's (HA).

BREEDING. Unrecorded.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.; Hume, 1874, SF 2: 178-80.

MEASUREMENTS			
Wing	Bill (from cere)	Tarsus	Tail
♂♂ 202-222 } ♀♀ 195-212 }	28-30	20-21	290-345 mm. (Baker)

The female has as long a tail as the male.

10 examples from the Nicobars in the Abbott collection, U.S. Nat. Mus., give

5 ♂♂ 200-215	29-32	19-23	308-358 mm.
5 ♀♀ 208-217	29-30	21-22	290-308 mm.

COLOURS OF BARE PARTS. Iris orange-red. Bill: upper mandible in ♂ coral-red, in ♀ black; lower mandible in both sexes black. Legs and feet plumbeous green (or plumbeous red, according to Baker).

554. Lord Derby's Parakeet. *Prittacula derbyana* (Fraser)

(No locality, cage bird)

Not in Baker, FBI

Plate 50, fig. 2

LOCAL NAMES. None recorded.

PSITTACIFORMES

174

(Baker). Courtship not described, but judging from mating behaviour is evidently of same pattern as Roseringed Parakeet's. 'While on female's back (for over two minutes) male's wings drooped limply at her sides as he actively trod her shifting from one foot to the other, his head bobbing quickly up and down, first on one side of hers then on the other as if kissing alternately on both cheeks' (SA).

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

MEASUREMENTS			
Wing	Bill (from cere)	Tarsus	Tail
♂♂ 162-174 } ♀♀ 157-162 }	23-28	16-17	{ 168-189 mm. 145-171 mm. (Baker)

COLOURS OF BARE PARTS. Iris, ♂ straw-yellow to bright pale yellow, ♀ whitish yellow. Bill, ♂ upper mandible coral-red, lower brownish black; ♀ upper mandible black, lower brownish black. Legs and feet dusky greenish yellow or pale yellowish slate.

552. Andaman Redbreasted Parakeet. *Prittacula alexandri abbotti* (Oberholser)

Corvus fasciatus abbotti Oberholser, 1919, Proc. Biol. Soc. Washington 32: 29 (South Andaman Island)

Baker, FBI No. 1508 (part), Vol. 4: 210

LOCAL NAMES. Unrecorded.

SIZE. As of 551; length overall c. 38 cm. (15 in.).

FIELD CHARACTERS. As of 551, q.v.; indistinguishable from it in the field. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Race peculiar to the Andaman Islands. Recorded from Middle and South Andamans, but doubtless occurs over the entire group wherever conditions favourable, with settlements and cultivation. 'Perhaps the commonest bird in the Andamans. Comes into Port Blair in tens of thousands in December and January, devouring the paddy' (Osmaston, 1906, JBNHS 17: 487). Not reported south of the Ten Degree Channel, in the Nicobar Islands.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 551, q.v.

BREEDING. *Season*, evidently chiefly February during which month Osmaston found numerous nests. *Nest*, eggs and clutch size as in 551.

MUSEUM DIAGNOSIS. Differs from *P. a. fasciata* in being larger and paler-coloured overall.

MEASUREMENTS			
Wing	Bill (from cere)	Tarsus	Tail
3 ♂♂ 170-174	28-31	13-14	187-193 mm. (BNHS Coll.)
8 ♀♀ 168-172	23-25	14-21 [!]	172-190 mm. (U.S. Nat. Mus. Coll.)

COLOURS OF BARE PARTS. As in the Indian form.

PSITTACIFORMES

176

SIZE. Myna ±; with long pointed tail. Overall length c. 46 cm. (18-19 in.).

FIELD CHARACTERS. Head violet-blue washed with green, with a narrow black band from eye to eye along base of bill, and a wide moustache of the same colour; underpart of neck, breast, and upper abdomen a fine purplish violet. Rest of plumage green, becoming yellowish on the wings and bluish on dorsal side of the tail. Bill red and black in male; all-black in female.

STATUS, DISTRIBUTION and HABITAT. Presumably summer visitor to NEFA in the Siang and Subansiri Divisions, as in adjacent SE. Tibet (between c. 2700 and 3500 m.), where according to Ludlow it only arrives during the first half of May and departs about end September. Evidently does not occur west of about the 93rd meridian.

Extralimital. SE. Tibet; SW. China in the provinces of Szechuan and Yunnan (Peters).

GENERAL HABITS. On arrival (in SE. Tibet), and before departure, seen in large flocks of 40 to 50 birds in cultivated valleys and conifer forest higher up. Noisy and very destructive to ripening crops.

FOOD. Barley, poplar catkins, cones of *Pinus tabulaeformis* and orchard fruit, according to season and availability.

VOICE and CALLS. Not described.

BREEDING. *Season* (in SE. Tibet) mid June. *Nest*, in holes in trees especially those of *Populus ciliata* (Ludlow, 1944).

MUSEUM DIAGNOSIS. Distinguished from *Prittacula a. fasciata* (551) chiefly by the green of the back running up on the nape and occiput (v. these parts concolorous with the crown). Breast much more lavender (v. vinaceous rosy), the colour extending considerably lower down towards vent than the rosy in *fasciata*.

MEASUREMENTS of specimens collected by F. Ludlow in SE. Tibet, Wing 3 ♂♂ 223-231; 5 ♀♀ 218-224 mm. (Kinnear).

COLOURS OF BARE PARTS. Iris greyish yellow. Bill: upper mandible in adult ♂ red, in ♀ and juv. ♂ black; lower mandible in both sexes black. Legs greenish grey; claws brown.

PSITTACULA LONGICAUDA (Boddaert)

Key to the Subspecies

- Back distinctly pale, tinged with lilac and blue... *P. l. tyleri* (♂♀)
Back almost concolorous with crown... *P. l. micberica* (♂♀)

555. Andaman Redcheeked Parakeet. *Prittacula longicauda tyleri* (Hume)

Palaermis Tyleri Hume, 1874, Stray Feathers 2: 454 (Andaman Islands; new name for *Palaermis effinis* Beavan, 1867, not of Gould, 1858)

Baker, FBI No. 1511, Vol. 4: 214

Plate 50, fig. 8

LOCAL NAMES. None recorded.

SIZE. Myna ±; with a very long pointed tail. Overall length c. 46 cm. (18 in.).

FIELD CHARACTERS. Redcheeked like 556, q.v., but both sexes less yellowish green and much bluer above and below.

STATUS, DISTRIBUTION and HABITAT. Resident and very common throughout the Andaman Islands, including Barren I., Narcondam, the Cocos, and Preparis. Affects cultivated areas and surrounding forest.

GENERAL HABITS. Keeps in vast flocks of thousands about fields of ripening paddy, to which the birds are enormously destructive (Butler, 1899).

FOOD. As of other parakeets — grain and fruit.

VOICE and CALLS. Unrecorded.

BREEDING. Season, February-March. *Nest*, a hole in a tree, very commonly a padouk (*Pterocarpus marsupium*), between about 4 and 8 metres up, growing near habitation or in forest. Eggs, two or three, white. Average size of 30 eggs 30.6 × 24.7 mm. (Baker).

MUSEUM DIAGNOSIS. Male distinguished from that of the Nicobar population (556) by the strong wash of violet on the upper back and blue on the lower back; underparts much less yellow, more tinged with bluish. Female also more bluish overall, and with the mandibular stripe all green instead of green-tinged black. Both sexes rather smaller than Nicobar birds.

MEASUREMENTS

	Wing	Bill (from cere)	Tarsus	Tail
♂♂	173-182	23-25	c. 19-20	235-253 mm.
♀♀	165-173	22-23	c. 17-18	178-204 mm. (Baker)

COLOURS OF BARE PARTS. As in 556.

556. Nicobar Redcheeked Parakeet. *Psittacula longicauda nicobarica* (Gould)

Palaeornis Nicobaricus Gould, 1857, Bds. Asia, pt. 9, pl. 13 [= 6, pl. 6 of bound vol.] (Nicobars). New name for *Palaeornis erythrogens* Blyth, 1846, not of Lesson, 1831 Baker, FBI No. 1510, Vol. 4: 213

LOCAL NAMES. *Talaka*, *Talahi* (Car Nicobarese).

SIZE. Myna ±; with a very long pointed tail. Overall length c. 48 cm. (19 in.).

FIELD CHARACTERS. Male (adult). Above, crown green; a black band of green-tipped feathers from nostril to eye; sides of head light brick-red; nape yellowish green with an indistinct lilac collar on hindneck. Upper back pale greyish yellow-green, interscapular region more bluish, rump bright green. Wings largely yellow-green and blue-green. Tail green-and-blue, the middle feathers largely blue. Below, chin and broad mandibular stripe to each side of neck black; rest of underparts green, yellower on throat and breast.

Female has the cheeks duller red and the mandibular stripe partially tinged with green. Rest of plumage, above and below, nearly uniform green.

STATUS, DISTRIBUTION and HABITAT. Resident. Nicobar Islands. Recorded in the 1870s and 90s as excessively abundant on all the islands of the group; presumably this status continues. Affects forest, gardens (kampongs), cultivation, and mangroves.

GENERAL HABITS. As in 555.

Madhya Pradesh to lat. 20°N., the arbitrarily fixed boundary where it intergrades with nominate *cyanocephala*. Affects well-wooded moist-deciduous plains and foothills country; avoids semi-desert areas.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 558.

BREEDING. Season, overall January to April, varying with locality. *Nest*, eggs, etc. as in the nominate race. Average size of 40 eggs 25.0 × 20.4 mm. (Baker).

MUSEUM DIAGNOSIS. Differs from the nominate form of south India and Ceylon (558) in being clinally larger, with the head paler coloured (less blue, more red) in the male. Tail much paler blue; rump, upper tail-coverts, under wing-coverts, and axillaries green (*contra* bluish green or verdigris). Birds approaching the 20th parallel are intermediate and can pass with either race.

MEASUREMENTS

	Wing	Bill (from cere)	Tail
♂♂	138-150	17-19	183-253 mm.
♀♀	135-144	16-18	185-200 mm. (Biswas)

Tarsus ♂♀ 14-16 mm. (SA).

Weight 2 ♂♂ 70, 71.5; 1 ♀ 66 gm. (GD).

COLOURS OF BARE PARTS. As in 558.

558. Southern Blossomheaded Parakeet. *Psittacula cyanocephala* (Linnaeus)

Psittacus cyanocephalus Linnaeus, 1766, Syst. Nat., ed. 12, 1: 141 (East Indies = Gingi, South Arcot district, Madras)

Psittacus rosa Boddaert, 1783, Table Pl. enlum.: 53 (Mahé; restricted to Chittagong by Whistler & Kinnear, 1935; re-restricted to Malabar coast by Biswas, 1951, loc. cit. *supra*)

Baker, FBI No. 1503, Vol. 4: 206 Plate 50, fig. 5

LOCAL NAMES. *Tūiya tātā* (Hindi); *Kerā* (Marathi); *Tūi* (Gujarati); *Rēma chiluka* (Telugu); *Pāmnū girāwā*, *Rosa girāwā* (Sinhala); *Kūli* (Tamil); *Poon tūtā* (Malayalam).

SIZE. Myna —; with a long, pointed tail. Overall length c. 36 cm. (14 in.).

FIELD CHARACTERS. A slender, dainty grass-green or yellowish green parakeet with bright bluish red or plum-coloured head, a black-and-verdigris collar, and a maroon-red patch on wing-shoulder. Broad white tips to the narrow, blue central tail-feathers particularly conspicuous in the swift arrow-like flight.

Female has the head duller and greyer, surrounded by a bright yellow collar. No neck-ring; maroon shoulder-patch absent or obsolete.

Young (immature) green overall, with the central tail-feathers shorter and broader. Tips of primaries more pointed than in adults. Dark head apparently acquired after the first winter.

STATUS, DISTRIBUTION and HABITAT. Resident, with marked local movements governed mainly by food supply. All peninsular India south of lat. 20°N. (the arbitrarily fixed boundary with 557), and Ceylon; lowlands and hills, locally up to c. 1300 metres. Affects moist-deciduous biotope — light

FOOD. As of other parakeets — grain and fruit. Items specifically recorded are papaya (*Carica papaya*), ripe pandanus fruit, and occasionally the outer covering of betel nuts (*Areca catechu*) — Davison, 1874, SF 2: 183.

VOICE and CALLS. Loud, not unlike that of *Psittacula krameri* (HA).

BREEDING. Season, evidently as in the Andamans, February-March. *Nest*, the only two known were in tree-holes on Trinkut I. c. 4 metres up in a *Pandanus* and 10 m. up in a large forest tree respectively. Each contained two young birds (Davison).

MUSEUM DIAGNOSIS. Both sexes rather larger and bluer than Andaman birds. For distinguishing from that population see under 555; for details of plumage Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from cere)	Tarsus	Tail
♂♂	186-192	26-28	18-20	250-286 mm.
♀♀	178-187	24-25		180-205 mm. (Baker)

6 ♂♂ ad. Wing 195-202 (av. 199.5); tail 240-290 mm. (HA).

COLOURS OF BARE PARTS. Iris yellow, creamy white, or pale brown. Bill: ♂ upper mandible vermilion, yellow at the tip, lower mandible horny black, yellowish horny, or dingy red; ♀ both mandibles blackish; in very young birds (both sexes) dull red. Legs and feet dull earthy or dingy green (Hume).

PSITTACULA CYANOCEPHALA (Linnaeus)

Cf. Whistler, H. & Kinnear, N. B., 1935, JBNHS 37: 752-3. Biswas, B., 1951, Amer. Mus. Novit., No. 1500: 1-8

Head in ♂ paler, less blue more red; under wing-coverts and rump (♂♀) bluish green *P. e. bengalensis*

557. Northern Blossomheaded Parakeet. *Psittacula cyanocephala bengalensis* (Forster)

Psittacus bengalensis Forster, 1781, in Pennant's Indian Zool.: 40 (Bengal; restricted to Calcutta by Whistler & Kinnear)

Baker, FBI No. 1502, Vol. 4: 204

LOCAL NAMES. *Fāridī* (= 'complainer'), *Tūi*, *Fūltūi* (Bengal); *Bengali tātā* (Punjab); *Dini tūiya*, *Lābirā tātā*, *Tūiya tātā* (U.P.); *Tūi sūgā* (Nepal).

SIZE. Myna —; with a long, pointed tail. Overall length c. 36 cm. (14 in.).

FIELD CHARACTERS. As of the southern bird (558), q.v.

STATUS, DISTRIBUTION and HABITAT. Resident, with local movements governed mainly by food supply. Roughly from about Rawalpindi (c. 73°E. long.) in West Pakistan eastward along the lower Himalayas through Jammu and Kashmir, Uttar Pradesh and Nepal to Bhutan duars and West Bengal; normally up to c. 600 metres, exceptionally and locally to c. 1500 m. Southward in the Gangetic Plain and through Saurashtra in Gujarat and

forest, well-wooded compounds, and cultivation; altogether less closely associated with man than Roseringed Parakeet.

GENERAL HABITS. Largely restricted to wooded country. Usually keeps in small parties of 5 to 10 birds, but in areas of food abundance, especially in cultivation within forest, often collects in very large flocks, of several hundred, committing serious depredations on ripening crops. Flight — aptly likened by one observer to 'a badly balanced arrow' — very swift, the flocks turning and twisting from side to side and in and out of the stems of forest trees with amazing agility. It is accompanied by a distinctive, interrogative, shrill but pleasant note *tooi?* or *tooi-tooi?* which, coupled with the prominent white-tipped blue tail, makes its identity unmistakable even while dashing past. Roosts in large noisy rabbles in bamboo clumps and *Butea* jungle, and the like.

FOOD. Grain and fruit of all kinds, buds, fleshy petals and nectar of flowers such as *Salmaia*, *Butea*, and *Bassia*. Figs of peepul and other *Ficus* species, and *bēr* drupes (*Zizyphus* spp.) are important 'wild' items. Very destructive to paddy (*Oryza*), jowar (*Sorghum*), maize (*Zea mays*), gram (*Gicer*), and vetches (*Dolichos lablab* and other species) commonly cultivated in forest clearings. Destructive also to orchard fruit.

VOICE and CALLS. Besides the shrill *tooi-tooi?* uttered in dashing flight, has a variety of soft musical conversational notes when at rest in company.

BREEDING. Season, chiefly December/January to April; in Ceylon occasionally also in July and August. *Nest*, as of other parakeets — a vertical shaft in a tree-trunk or bough with a neat round entrance-hole at the top, at moderate heights from the ground. Usually chiselled out by the birds themselves (both sexes), but old nest-holes of small woodpeckers and barbets, enlarged to suit, also freely utilized. Nest unlined, but sometimes with a little chance debris of wood-chips fallen in during excavation. F. N. Betts observed that this species chisels out long slivers of wood unlike other parakeets which bite off dice-shaped pieces. Several pairs often nest in a loose colony in the same or adjacent tree-trunks. Eggs, 4 or 5 — rarely 6 — white, more spherical than of most other parakeets. Average size of 50 eggs 24.9 × 20.2 mm. (Baker). As far as observed the hen alone incubates; share of the male, if any, and period of incubation undetermined. Nestlings fed by regurgitation, apparently also by the hen alone.

Courtship pattern and antics mainly as in Roseringed Parakeet (549), q.v.

MUSEUM DIAGNOSIS. Clinally smaller than the northern *bengalensis* (557). Head richly coloured in male (more blue, less red). Tail much darker blue; rump, upper tail-coverts, under wing-coverts, and axillaries bluish green or verdigris (*contra* green). Birds approaching the 20th parallel are intermediate and can pass with either race. For details of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from cere)	Tail
♂♂	132-145	16-19	180-210 mm.
♀♀	126-140	16-18	164-176 mm. (Biswas)

Tarsus 13-15 mm. (SA).

Weight 9 ♂♀ 56-70 gm. (av. 65) — SA.

PARROTS

181

COLOURS OF BARE PARTS. Iris yellowish white. Bill (paler in ♀): upper mandible pale orange-yellow; lower blackish brown, pale flesh colour at chin. Legs and feet greenish grey; claws horny.

MISCELLANEOUS. Like other parakeets extremely wasteful in its feeding habits and wholly injurious from the economic point of view. Is a popular and ornamental though rather uninteresting pet. May learn to whistle snatches of some simple tunes, but has no claim to talking ability.

Psittacula roseata BiswasKey to the Subspecies
(Males only)

Green above and below; red patch on upper wing-coverts smaller; under wing-coverts green..... *P. r. roseata*
Similar to above but more yellowish; red patch on upper wing-coverts larger..... *P. r. juneae*

559. Assam Blossomheaded Parakeet. *Psittacula roseata roseata* Biswas

Psittacula roseata Biswas, 1951, Amer. Mus. Novit., No. 1500: 4
(Gunjong, North Cachar, Assam)

Included by Baker under FBI No. 1503

Plate 50, fig. 7

LOCAL NAMES. *Daobator kashiba* (Cachar); *Assāmi fūltūsi* (Calcutta bird dealers).

SIZE. Myna —; with a long, pointed tail. Overall length c. 36 cm. (14 in.).

FIELD CHARACTERS. As of the Indian Blossomheaded parakeets (557, 558), q.v. Indistinguishable from 557 in the field. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident, with the usual local movements governed by food supply. Lower Himalayas and duars of Sikkim, Bhutan and northern Bengal; Assam; East Pakistan. Intergrades with *P. r. juneae* (560) in southeastern E. Pakistan (Tripura area) roughly around 91-92°E. longitude. Affects well-wooded country, light forest, and cultivation in jungle clearings.

Extralimital. 'Upper Burma' (Biswas).

GENERAL HABITS, FOOD, VOICE and CALLS. As in 558, q.v.

BREEDING. Season, chiefly January to March/April; in the Assam hills sometimes continuing into early May. Nest and eggs as in 557.

MUSEUM DIAGNOSIS. The species *Psittacula roseata* differs from *P. cyanocephala* in having the forehead, cheeks, and ear-coverts rosy pink instead of red; the crown bluish lilac; back and rump green; no verdigris collar; the colour of the patch on wing-coverts between Morocco Red and Claret Brown of Ridgway (1912, pl. 1); under wing-coverts green and not verdigris; tips of central rectrices pale yellow; tail conspicuously shorter. The nominate subspecies is larger and darker; the patch on the wing-coverts is smaller (Biswas).

MEASUREMENTS

	Wing	Bill (from cere)	Tail
♂♂	139-150	18-20	155-195 mm.
♀♀	137-143	18-19	140-163 mm.

(Biswas)

COLOURS OF BARE PARTS. As in 558.

PARROTS

183

The seventh specimen, immature (sex ?), is green overall and matches well in coloration and size immature examples of *Psittacula himalayana*.

COLOURS OF BARE PARTS. Unrecorded.

562. Himalayan Slatyheaded Parakeet. *Psittacula himalayana* (Lesson)

Psittacus (Corvus) Himalayanus Lesson, 1832, in Belanger's Voy. Ind. Orient, Zool.: 239 (Valleys of the Himalayas)

Palaeornis schisticeps Hodgson, 1836, Asiatic Res. 19: 178 (Nepal)

Baker, FBI No. 1504, Vol. 4: 206

Plate 50, fig. 6

LOCAL NAMES. *Tātā, Shōgā* (Kashmir); *Pāhāri tūyā* (U.P.); *Mādānā sūga* (Nepal); *Gāgi, Pāhāri tātā, Pāhāri mādnā* (Calcutta bird dealers).

SIZE. Myna; with a long, pointed tail. Overall length c. 41 cm. (16 in.).

FIELD CHARACTERS. A grass-green parakeet with the entire head dark bluish slaty in the male. Chin and a narrow black ring encircling neck followed by a bright verdigris-green collar on hindneck; a prominent dark red patch on wing-shoulder (secondary coverts). Tail steeply graduated, all the feathers broadly tipped with bright pale yellow, particularly the narrow, pointed, blue middle pair.

Female similar but without the red shoulder-patch.

Both sexes readily distinguishable from Blossomheaded Parakeet by dark slaty head v. bluish red or grey, and bright yellow tail-tip v. white, these features striking even in a flashing fly-past.

Young (immature) green overall, apparently acquiring the dark head after the first winter.

STATUS, DISTRIBUTION and HABITAT. Resident, migrating altitudinally in winter and with marked nomadic wanderings governed by food supply. The Himalayas from the Afghan frontier in West Pakistan (Kohat, Kurram, Chitral) eastward through Kashmir, Garhwal, Kumaon, Nepal and Sikkim to Bhutan and western Assam — roughly to around 92°E. longitude. At higher elevations than other parakeets, chiefly between c. 600 metres (winter) and 2500 metres (summer); occasionally down to 250 m. locally. Affects well wooded hillsides and valleys; especially partial to deodar forest and the neighbourhood of terraced cultivation and hill orchards.

GENERAL HABITS. Keeps more to forest than other parakeets, in family parties and small flocks; nowhere as abundant or in such large congregations as e.g. the Blossomheaded. Like other parakeets clammers among the foliage and branches in hand-over-hand fashion aided by the hooked bill for leverage. Flight very swift and direct, accompanied by a high-pitched double note, the birds turning, twisting, and banking in unison to weave their way through the forest trees with remarkable agility, the whole flock suddenly swinging upwards to alight in the foliage canopy.

FOOD. Nuts, acorns, seeds, and fruits — wild as well as cultivated. Very destructive to walnuts, and apples and pears in hill orchards, gnawing into the half-ripe fruit and wasting far more than it actually consumes. Is a local pest of maize in upland valleys.

VOICE and CALLS. The high-pitched double scream *too-too?* uttered in flight is like the Blossomhead's but harsher and quite distinctive: rather

182

PSITTACIFORMES

560. Arakan Blossomheaded Parakeet. *Psittacula roseata juneae* Biswas

Psittacula roseata juneae Biswas, 1951, Amer. Mus. Novit., No. 1500: 5
(Arakan, Burma)

Included by Baker under FBI No. 1503

LOCAL NAMES. Not specifically recorded. *Tenawā* (for parakeets generally, Manipur).

SIZE. Myna —; with a long, pointed tail. Overall length c. 36 cm. (14 in.).

FIELD CHARACTERS. As of 558. Indistinguishable in the field from other Blossomheaded parakeets. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. The Tripura area (roughly around longitude 91-92°E.) where the population intergrades with nominate *roseata*; Mizo (?); Manipur (?); Chittagong, E. Pakistan(?).

Extralimital. 'Arakan, Lower Burma south to Tavoy district, Siam, and Indochina [Vietnam, Laos, Cambodia]' (Biswas).

BREEDING. As in 557; nothing specifically recorded.

MUSEUM DIAGNOSIS. 'Similar to *roseata* but more yellowish, both above and below; the central tail-feathers less bluish; the patch on the wing-coverts more extensive on the average; wing smaller' (Biswas).

MEASUREMENTS of intermediate examples from the Tripura area: 4 ♂♂ Wing 137-145; bill (from cere) 18-19; tail 170-198 mm.

COLOURS OF BARE PARTS. As in 558.

561. Rothschild's Parakeet. *Psittacula intermedia* (Rothschild)

Palaeornis intermedia Rothschild, 1895, Nov. Zool. 2: 492 (India)

Cf. Hartert, E., 1924, Nov. Zool., 31: 126

Not in Baker, FBI

LOCAL NAMES. Unrecorded.

SIZE. About that of the Himalayan Slatyheaded Parakeet (562).

FIELD CHARACTERS. Presumably more or less as of 562, q.v., but never consciously seen alive in the wild state by any ornithologist.

STATUS, DISTRIBUTION and HABITAT. Completely unknown. Originally described from a single trade skin (the Type) of unknown provenance — allegedly 'Native Sikkim' — shipped from Bombay along with two skins of *Psittacula himalayana*. Six more were obtained later from a London plume dealer. These 7 specimens — all that are known — are now in the Rothschild Collection, American Museum of Natural History, New York.

GENERAL HABITS, FOOD, VOICE and CALLS. Unknown, but presumably not different from its putative parent stocks.

MUSEUM DIAGNOSIS. Superficially a hybrid between *Psittacula himalayana*/*P. finschii* and *Psittacula cyanocephala*/*P. roseata* sharing many characters with both the groups. Approximates in coloration to the Blossomheaded species, and in size to the Slaty-headed. For a discussion and analyses of the shared characters see Biswas, 1959 JBNHS 56: 558-62.

MEASUREMENTS

	Wing	Bill (from cere)	Tail
6 ad. [♂]	148-158	19-21	185-221 mm. (3 measured) (Biswas)

184

PSITTACIFORMES

reminiscent of the shrill 'whistles' of a marmot. A single high-pitched shriek commonly uttered at rest; also a variety of softer and more musical conversational notes when in company.

BREEDING. Normally up to c. 2500 metres. Season chiefly March to May, varying with altitude. Nest, a natural hollow in a tree-trunk, or old woodpecker or barbet hole, chiselled out to suitable size, or one self-excavated by the birds, between c. 6 and 18 metres up. Sometimes several holes in the same or adjacent trees in forest occupied in a loose colony. Eggs, 3 to 5 — most commonly 4 — white, glossless, rather spherical ovals. Average size of 40 eggs 28.3 × 22.2 mm. (Baker). Share of the sexes in the domestic chores presumably as in Blossomhead but not specifically recorded. Incubation period undetermined.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit. Differs from the allied eastern species (563) by darker plumage, including slate colour of head. Wing longer; central tail-feathers shorter and broader (breadth near tip c. 11 mm.) in both sexes.

MEASUREMENTS

	Wing	Tail
39 ♂♂	157-175 (av. 166)	38 ♂♂ 175-275 (av. 233) mm.
11 ♀♀	153-165 (av. 160)	11 ♀♀ 149-275 (av. 200) mm.

(K. Z. Husain)

Tarsus 12-13 mm.; bill (from cere) 20-22 mm. (Baker).

COLOURS OF BARE PARTS. Iris creamy white to lemon-yellow. Bill: upper mandible orange, reddish at base, yellow at tip; lower mandible yellow. Legs and feet yellowish green; claws plumbeous horn.

563. Eastern Slatyheaded Parakeet. *Psittacula finschii* (Hume)¹

Palaeornis Finschii Hume, 1874, Stray Feathers 2: 509

(Kollidoo, 3500-5000 ft, upper Salween River, Burma)

Baker, FBI No. 1505, Vol. 4: 208

Plate 50, fig. 4

LOCAL NAME. *Daobator kogashim* (Cachar).

SIZE. Myna; with a long, pointed tail. Overall length c. 36 cm. (14 in.).

FIELD CHARACTERS. A slatyheaded hill-forest parakeet, indistinguishable from 562 in the field. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. From southeastern Bhutan and western Assam east and south through NEFA, the rest of Assam, Nagaland, Manipur, Mizo, and East Pakistan (Sylhet-Chittagong area); foothills and up to c. 2100 m. Affects hill forest and cultivation.

Extralimital. W. Yunnan, Burma south to Tenasserim, N. Thailand, southern Laos, and central Vietnam.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 562, q.v.

¹ Treated as a race of *Psittacula himalayana* in Synopsis. The fact of sympatry (overlapping breeding distribution) in the duars area of northern Bengal and southeastern Bhutan apparently without hybridization, pointed out by K. Z. Husain (1959, *Ibis* 101 (2): 249-50) and confirmed by Biswas (1960, JBNHS 57: 538), necessitates this change in its taxonomic status.

PARROTS

185

BREEDING. Season, February to May. Nest, eggs, etc. as in *P. himalayana*. Average size of 30 eggs 27.1 × 21.5 mm. (Baker).

MUSEUM DIAGNOSIS. Similar to *P. himalayana* (562) sex for sex, but paler overall including slate colour of head. Back more yellow; central tail-feathers a paler lilac-blue in the middle and duller lilac-yellow on the terminal halves; under wing-coverts and axillaries a darker blue-green. Wing shorter; central tail-feathers much longer and narrower (breadth near tip c. 5 mm.) in both sexes.

MEASUREMENTS

	Wing	Tail
34 ♂♂	145-155 (av. 150)	32 ♂♂ 240-305 (av. 270) mm.
10 ♀♀	141-149 (av. 143)	9 ♀♀ 212-250 (av. 223) mm.

(K. Z. Husain)

COLOURS OF BARE PARTS. Iris creamy white to yellow. Bill: upper mandible coral-red or vermillion, tipped yellow; lower mandible all yellow. Legs and feet dirty green (Baker).

564. *Bluewinged Parakeet. Psittacula columboides* (Vigors)*Palaeornis columboides* Vigors, 1830, Zool. Jour. 5: 274

(No locality = Aneichardi, Travancore)

Baker, FBI No. 1506, Vol. 4: 208

Plate 50, fig. 10

LOCAL NAMES. *Mādāngour lōā* (Hindi; of bird dealers?); *Nīlātātā* (Malayalam). **SIZE.** Myna ±; slenderer and with a long, pointed tail. Overall length c. 38 cm. (14½ in.).

FIELD CHARACTERS. A bluish green (rather than grass-green) parakeet with pinky grey head, back and breast, and a brilliant blue-green and black collar round occiput. Lower back, rump, and upper tail-coverts greenish blue. Wings and central tail-feathers conspicuously blue, the latter tipped with yellow.

Female lacks the blue-green or verditer collar behind the black neck-ring and has the dove-grey on back and breast less pure in tint.

Young (immature) more or less entirely green with the collar only faintly indicated. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident, with the usual nomadic wandering in quest of food. The Western Ghats complex from Kerala north to c. 19°N. lat. (Kasa in Thana dist., north of Bombay) including the Nilgiri, Palni, and associated hills of Tamil Nadu and Mysore States—chiefly between c. 500 and 1500 m. alt. Not in Ceylon. Restricted to evergreen biotope but wandering into the intermediate zone to about the same limit as *P. cyanocephala* does from the deciduous end. Both species frequently occur together in low foothills country; only the Bluewinged at higher elevations.

GENERAL HABITS. Keeps in parties of 4 or 5, or small flocks, to forested hillsides in the vicinity of hillmen's settlements and cultivation or *poddus*.

PARROTS

187

released after their graduation is not clear. But they were regularly fed and so kept in the neighbourhood of the holy man's abode. To his glorification they caused open-mouthed wonderment amongst the devout who pilgrimaged to the saint periodically, and who helped later to broadcast the magical piety of Bābūddin and the spell it had cast upon the parakeets of the locality!

565. *Layard's Parakeet. Psittacula calthorpae* (Blyth)*Palaeornis Calthrapae* (sic) 'Layard' = Blyth, 1849, Jour. Asiat. Soc. Bengal 18

(2): 800 (Ceylon)

Baker, FBI No. 1507, Vol. 4: 209

Plate 50, fig. 12

LOCAL NAMES. *Alu girāwā* (Sinhala); *Kili* (Tamil).

SIZE. Myna —; slenderer, with a long, pointed tail. Overall length c. 31 cm. (12 in.).

FIELD CHARACTERS. A slim green parakeet, superficially very like the Bluewinged (564) of southwestern India, but ♂ with green wings (v. blue), bluish crown and upper back (v. grey) and green breast instead of grey.

Male (adult). Above, forehead, lores and a patch round eye green; rest of head, nape, and upper back bluish grey; a conspicuous broad emerald green and black collar. Lower back, rump, and upper tail-coverts blue. Central tail-feathers deep purplish blue tipped with greenish yellow.

Female similar to ♂ but duller green on the face, and with black instead of red upper mandible.

Young (immature) green throughout except the tail which is blue.

STATUS, DISTRIBUTION AND HABITAT. Species peculiar to Ceylon. Resident; moderately plentiful in the wooded areas of the hills to c. 1800 metres and throughout the greater part of the lowlands (both Wet and Dry zones) to the east and southeast of the mountains (Phillips). An unconfirmed sight record in January on Hulule Island, N. Mahé Atoll, Maldives (Gadow & Gardiner, 1903). Probably escapes.

GENERAL HABITS. Principally a hill parakeet though descending locally to nearly sea level in the Wet zone. Coincident with the Blossomhead (558) over much of its range. Keeps in fair-sized flocks on the outskirts of woods, in open spaces in the jungle, and in the wooded gorges of the *palanas* (open stretches of grassland). Flight and general behaviour not significantly different from 558.

FOOD. Fruits, flowers, buds, nectar, etc.; 'less destructive to grain fields than the Blossomhead and Roseringed Parakeets, being more definitely arboreal than they' (Henry).

VOICE AND CALLS. A loud, harsh chattering scream *ak ak ak ak* (Henry).

BREEDING. Season, 'January to May, and often again in July-September' (Henry). Nest, a tree-hole as in other parakeets, usually high up, sometimes in the top of a dead coconut palm. Eggs, 2 or 3, white, glossless, broad ovals. Average size of 9 eggs 24.7 × 19.2 mm. (Baker). Share of the sexes in the domestic chores and incubation period unrecorded.

186

PSITTACIFORMES

Secondary jungle on old forest clearings and abandoned coffee and rubber plantations are favourite haunts. Flight and general behaviour as in the Blossomhead Parakeet.

FOOD. Grain, seeds, and fruits—especially the various wild figs (*Ficus*). Also buds, petals and flower nectar, *Erythrina* and *Grevillea*, so widely grown as shade trees in South Indian tea and coffee plantations, being regularly patronized. Very destructive to jowar (*Sorghum*) and other cereals and vetches (*Dolichos*) in hillmen's cultivation; also to orchard fruit.

VOICE AND CALLS. A double-noted cry like the Blossomhead's but harsher and distinctive. Uttered chiefly on the wing, and rather reminiscent of the harsh *che-chue* of Paradise Flycatcher (*Terpsiphone*), but much louder. Parties very noisy.

BREEDING. Season, January to March. Nest, a hole in a tree-trunk in forest, coffee plantations, and the like between c. 6 and 30 metres from the ground. Lofly ironwood trees (*Mesua ferrea*) seem particularly favoured in spite of the considerable extra effort it must involve to chisel this hard wood. Readymade woodpecker and barbet holes are also altered to suit and utilized. Eggs, normally 4, white, spherical. Average size of 25 eggs 28.3 × 24.5 mm. (Baker). Share of the sexes in the domestic chores, and incubation period, undetermined.

MUSEUM DIAGNOSIS. For details of adult male plumage see Baker, loc. cit.

Female (adult) differs in having the green wash on forehead and lores reduced to a minimum; no ring of verditer green behind the black neck-ring; grey of breast less pure in tint.

Young (immature). Sexes alike. Entire head, hindneck, mantle, and underparts green, with the neck rings only shadowed in verditer and black. Scapulars, wing-coverts, and inner secondaries more green, less blue; pale edging to wing-coverts less defined; central tail-feathers shorter and broader. Adult plumage attained with first complete moult. On leaving nest both sexes have red bills like adult males. They rapidly darken to black as in adult female, that of male again reverting gradually to red within the first year.

MEASUREMENTS

	Wing	Bill (from cere)	Tarsus	Tail
♂♂	142-156	22-26	14-18	204-246 mm.
♀♀	135-145			170-190 mm. (SA)

COLOURS OF BARE PARTS. Iris pale golden to bright yellow. Bill: ♂ upper mandible scarlet or cherry-red with yellow tip; lower mandible horny brown tinged with orange at chin, yellowish at tip; ♀ both mandibles dark horny brown or blackish, tinged with orange at chin. Legs and feet greenish grey; claws horny brown.

MISCELLANEOUS. Much prized by fanciers as the 'Bababudan Parrot', this species has acquired a spurious reputation, especially in Mysore, as a talking paragon, being able to converse with humans in Arabic! The basis for this widespread belief appears to be that one Bābūddin, a pilgrim from Mecca (and incidentally the introducer of coffee from Yemen into S. India) who settled on the hills that now bear a semblance of his name (Bababudan), kept some local parakeets whom he taught to call to Allah and recite verses from the Koran. Whether some of his trained birds escaped or were artfully

Plate 50, fig. 14

LOCAL NAMES. *Lūkōn*, *Bhōra* (Hindi, Bengali); *Daobator lai* (Cachar); *Tāttichinnar* (Malayalam); *Chrey* (Marathi).

SIZE. Sparrow ±; length c. 14 cm. (5½ in.).

FIELD CHARACTERS. A diminutive, dainty, bright grass-green parrot with short square tail and rich crimson rump. A small blue patch on throat of male.

Female similar to male but lacking the blue throat-patch.

Young (immature) has the red rump mixed with green. See also Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident; with a wide range. Also subject to local migrations as yet little understood, but apparently not altogether connected with food supply: rains visitor in certain parts, winter visitor in others. Nepal, Sikkim, Bhutan, NEFA, Assam, Nagaland, Manipur, Mizo (?), Tripura, and East Pakistan (Tippera, Sylhet, Chittagong); Western India—coastal strip and Ghats—from north of Bombay (c. 19°N. lat.) southward, including the Nilgiris, Palnis, and associated hills of Mysore, Tamil Nadu, and Kerala States; thence north along the Eastern Ghats through eastern Madhya Pradesh and Orissa; plains, and foothills normally up to c. 1000 m.; in the Nilgiris to c. 1800 m. Also Andaman and Nicobar

PARROTS

189

Islands (very common). Affects wooded country in evergreen and moist-deciduous biotopes.

Extralimital. Arakan, central and southern Burma to Tenasserim, Thailand, and the Indochinese countries.

GENERAL HABITS. Keeps in pairs or family parties — sometimes small loose flocks of up to 50 or more where the feeding is good, as in a grove of flowering trees. Their diminutive size and concealing coloration make the birds difficult to observe in the canopy of the tall trees they usually frequent; oftener seen when dashing from one tree to another. They have a curious way of ascending a branch in a spiral course around it, clambering energetically — almost at a run — among the trusses and leaf-stalks, aided by bill and feet, and seem just as much at home hanging upside down or sideways as perched the right way up. Flight very swift, rather finch-like, consisting of several rapid 'vibrating' wing-strokes punctuated by a short pause with wings closed and a consequent dip. It is invariably accompanied by a shrill trisyllabic bat-like squeak *chi-chi-chee* repeated every couple of seconds or so. These characteristic cries, sometimes also uttered when clambering about in the foliage, are often the only indication of the presence of the birds in a locality. Lorikeets possess one very unorthodox peculiarity, unique among Indian birds, that of sleeping at night hanging upside down like a bat.¹ Another unique habit of the female (or both sexes?), of conveying strips specially cut out of green leaves for nest lining tucked under her rump feathers, as in the small African parrots or Love Birds (*Agapornis*), has not been observed in India, but see under Ceylon Lorikeet (568). For details of behaviour see Buckley, Francine G. (1968), 'Behaviour of the Blue-crowned Hanging Parrot, *Loriculus galgulus*, with comparative notes on the Vernal Hanging Parrot, *L. vernalis*'. *Ibis*, 110: 64; for courtship and mating, Neelakantan, K. K., 1974, JBNHS 70: 554-6.

FOOD. Soft pulp of fruits and berries, chiefly wild figs (*Ficus* spp.), largely supplemented by flower nectar. Flowers of the parasitic Loranthaceae and of *Salmaia malabarica*, various species of *Erythrina*, and of many introduced

Eucalypti are irresistible, the trees often 'crawling' with these little birds in season. Unlike the parakeets they do not destroy the floral parts of non-tubular blossoms to reach the nectar, and by transporting pollen adhering to their head-feathers must play a helpful role in cross-fertilization. Fond of coconut palm toddy, bibbing from the pots hung up for collecting the juice, sometimes becoming stupefied and helpless as a result. Partial to seeds of casuarina, bamboo, and teak (*Tectona grandis*) in forest and plantations, and to guavas (*Psidium*) and

loquats (*Eriobotrya japonica*) in orchards, often doing considerable damage locally.

VOICE AND CALLS. As above. Normally very quiet.

BREEDING. Overall January to April; in the Andamans chiefly January and February. *Nest*, a vertical or oblique natural hollow in a rotten tree-stem or branch sometimes up to a metre in depth, enlarged to suit where

¹ In captivity some other members of the Pittacidae, e.g. *P. cyanocapilla*, frequently sleep clinging to the wire-netting of their cages upside down but not freely suspended like bats.

× c. 1

CUCKOOS

191

wandering higher seasonally with fruit ripening. Affects wooded country in evergreen and moist-deciduous biotopes.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in Indian Lorikeet (566), q.v. Courtship described by Henry (1955: 189). Male strikes ridiculous postures before female, struts along the perch towards her with jerky gait and short hops, beak held high, blue throat-feathers puffed out; tail spread, and scarlet rump-feathers raised, all the while uttering a squeaky warble. Further sequences not recorded. Female procures the nest-padding material by nibbling strips from the edges of green leaves, tucking one end into the bases of the scarlet rump-feathers and flying off when a rumpful has been collected.

BREEDING. *Season*, January to August, chiefly March to May. *Nest*, similar to Indian Lorikeet's: a narrow vertical or oblique hollow in a tree-stump or branch with entrance near the top, padded with strips of green leaves. *Eggs*, 2 or 3, white, nearly spherical. Size c. 19 × 16 mm. Apparently the female alone incubates, or largely so; period undetermined. 'She sits very close and, if interfered with, voices her displeasure in angry screechings and, in some mysterious way, produces an extraordinary, heavy, thumping sound, suggestive of pounding the inside of the hollow with a sledge-hammer' (Henry).

MUSEUM DIAGNOSIS.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂ ♀	90-98	12-13 (from cere)	10-12	36-44 mm. (HW)

COLOURS OF BARE PARTS. Iris white. Bill light orange-red, paler at tip, yellow on cere. Legs and feet dusky yellow.

Order GUCULIFORMES

Family GUCULIDAE: Cuckoos

Feet zygodactyle, the first and fourth toes directed backwards. Contour feathers without any afterfeather; dorsal feather-tract divided between the shoulders and enclosing a lanceolate naked patch on the back; a nude oil gland present. Young nidicolous — hatched naked and not passing through a downy stage before acquiring feathers. Tail-feathers 10 in all Oriental genera. For general information see Thomson, A. L. (ed.) 1964, *New Dict. Birds* (Article 'Cuckoo'): 169-71; for morphological details Stresemann, E., 1927-34, *Aves*: 817-20; Baker, 1927, FBI 4: 133.

The family has an almost world-wide distribution, but its members are most numerous in the tropics. They are best known for their habit of brood-parasitism: building no nests of their own, laying their eggs in the nests of other birds, and foisting on them the labour of incubating them and bringing up the young. One section of the family is non-parasitic, whose breeding habits are normal as in most other birds. Both groups are well represented in India and Pakistan.

In spite of all that has been published in literature by Stuart Baker and others, unequivocal data on the breeding biology of Indian parasitic cuckoos are, by and large, lacking. Much of what exists is of a dubious nature, and even some of the eggs ascribed to this or that species appear to be wrongly identified. A thorough-going and *de novo* investigation of our cuckoo problems is an urgent need, and reference is invited to J.H. Becking's 'Notes on the Breeding of Indian Cuckoos' (JBNHS).

190

PSITTACIFORMES

necessary, and with entrance from the top or through a lateral hole between 2 and 10 metres from the ground. Usually lined with a pad of cut out strips of green leaves. In the Andamans, Osmaston found nests at the bottom of holes in stumps, the eggs being laid below ground level. *Eggs*, 3 or 4, white, rather spherical and glossy, often stained brownish by contact with rotten wood of nest-interior during incubation. Average size of 30 eggs 19.1 × 15.8 mm. (Baker). Apparently both sexes incubate, but female takes the major share. Close sitter, only uttering a long-drawn querulous *chee-ee* when nest about to be handled, without forsaking the eggs. Incubation period undetermined. Both parents feed the nestlings by regurgitation.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit. The subspecies *rubropygialis* erected by Baker for south Indian birds and included in *Synopsis* (567) cannot be sustained. The northern and southern populations, assumed to be disjunct at the time, have since proved to be continuous. The supposed characters on which the race was based — darker coloration above and below, deeper duller red rump, and darker undersurface of tail and wing-quills — are evidently due to individual variation or wear, or both.

Young (immature) differs from adult in the paler blue of the abdomen and absence of any purple wash on chin and throat. Tail-feathers much narrower with the outer pair more rounded at the tips.

MEASUREMENTS

♂ ♂	91-102	11-15	10-12	38-45 mm.
♀ ♀	96-100	11-15	10-12	45-48 mm. (SA, HW)

COLOURS OF BARE PARTS. Iris yellowish white, brownish buff, or greyish khaki. Bill reddish orange or coral-red, yellower at tip. Legs and feet pale orange or pale yellowish slate; claws horny brown.

568. Ceylon Lorikeet. *Loriculus beryllinus* (J. R. Forster)

Pittacus beryllinus J. R. Forster, 1781, Indische Zool.: 40 (Ceylon)
Baker, FBI No. 1515, Vol. 4: 219

Plate 50, fig. 13

LOCAL NAMES. *Girā malichā*, *Pol girāwā* (Sinhala); *Kāmi kili*, *Thēmāng kili* (Tamil).
SIZE. Sparrow ±; length c. 14 cm. (5½ in.).

FIELD CHARACTERS. A diminutive bright grass-green parrot with short square tail, exactly like Indian Lorikeet but with the crown rich crimson, in addition to rump, passing into orange on nape and into yellowish-tinged hindneck and upper back.

Female similar to male but duller coloured with merely a trace of the blue throat-patch.

Young (immature) lacks the crimson crown; at time of leaving nest, though fully fledged, has the whole forehead and face naked (Henry).

STATUS, DISTRIBUTION AND HABITAT. Species peculiar to Ceylon. Abundant, locally throughout the lowlands and hills up to c. 1300 metres,

Genus CLAMATOR Kaup

Clamator Kaup, 1829, Skizz. Entw.-Gesch. Eur. Thierw.: 53. Type, by original designation and monotypy, *Cuculus glandarius* Linnaeus

Genus distinguished from all others of the family by having a long pointed crest. Wing short and rounded, the primaries not exceeding the secondaries by more than one-fourth the length of the wing. Bill compressed, culmen much curved towards tip. Tarsus feathered at base only. Tail much longer than wing; well graduated. Sexes alike.

Cuculus coromandus Linnaeus, 1766, Syst. Nat., ed. 12, 1: 171

(Coromandel = Pondichery)

Baker, FBI No. 1474, Vol. 4: 170

Plate 52, fig. 3

LOCAL NAMES. *Tsaben* (Lepcha); *Terra golā kēkilā* (Telugu); *Uppān kiyil* (Malayalam); *Ratu kōndē kōhā* (Sinhala); *Kōndē kiyil* (Tamil).

SIZE. House Crow +; slenderer. Length c. 47 cm. (c. 18 in.).

FIELD CHARACTERS. A largish, crested cuckoo similar in overall effect to the more familiar Pied Crested (570) but metallic glossy black above interrupted by a white half-collar on hindneck, and with chestnut wings as in Crow-Pheasant. *Below*, chin, throat, and upper breast rust-coloured; rest of lower parts white or whitish. When flying across observer's front, crested head, white nuchal collar, red wings, and whitish underparts are diagnostic pointers. Sexes alike.

Young (immature). *Above* brown, the feathers (including wing-coverts) broadly edged with rufous; *below* white.

CUCKOOS

193

In older young when glossy black upper plumage first assumed, many feathers, especially on the wings, still fringed with rufous, and tail tipped with dull buff instead of white.

STATUS, DISTRIBUTION AND HABITAT. Breeding and apparently resident in the Himalayan duns, duars, and foothills (up to c. 1500 metres altitude) from Garhwal and Kumaon eastward through Nepal, Sikkim, N. Bengal, Bhutan and NEFA; in the Assam hills (Garo, Khasi, N. Cachar, etc.), and probably in Nagaland, Manipur, Mizo, and also in East Pakistan (Tippera, Chittagong). Common in eastern Assam. In peninsular India recorded variously as on passage, or a rare straggler, or scarce but regular rainy season or winter visitor, in Kerala, Mysore, Tamil Nadu, and Maharashtra States; status and movements very imperfectly known or understood. Regular winter visitor in small numbers to Ceylon, up to c. 2000 metres, from about October/November to April. Affects evergreen and moist-deciduous biotopes: foothills forest, and scrub-and-bush jungle.

Extralimital. Malay Peninsula, Sumatra, Lingga Archipelago, Borneo, Java during northern winter only, as in Ceylon (Stresemann, *in epist.*).

MIGRATION. On passage (to Sri Lanka?) in numbers through Pt Calimere (10°18' N., 79°51' E.), mid-October.

GENERAL HABITS. Keeps singly or in loose parties of 3 or 4. Not shy but rather retiring. Strictly arboreal, preferring the foliage canopy of trees in forest, but frequently descends into undergrowth of scrub and bushes, skulking about silently in search of food. Actions and behaviour very like Pied Crested Cuckoo's. Flight swift and direct though seeming somewhat leisurely, with quick wing-beats like Koel.

FOOD. Mainly caterpillars.

VOICE AND CALLS. A harsh grating or rasping scream resembling the cry of the jay or magpie, but more so (B. B. Osmaston). Also a quite different 'bisyllabic whistling note very like Collared Pygmy Owl (*Glaucidium brodiei*) but with more metallic sound' uttered at night (H. H. Harington). Bird rather silent in winter; reportedly very noisy in breeding season.

BREEDING. Brood-parasitic mainly on Himalayan laughing thrushes (*Garrulax* spp.), the commonest fosterers being *Garrulax pectoralis* and *G. moniligerus*. (For a list of other fosterers see Baker, 1942: 196-7.) Season, synchronous with that of the fosterers: overall April to August, principally May and June. Eggs, pale hedge-sparrow blue, unmarked, very broad ovals, fine-textured, glossless; matching perfectly the eggs of the fosterers and normally indistinguishable from them except by more spherical shape. Usually 2 or more (up to 4 recorded) eggs are laid in the same nest which, from their similarity in colour, shape and size could all well be the product of one and the same female. Evidently some of the rightful eggs are removed to make room, but a much more thoroughgoing study of the Indian cuckoos is desirable for elucidating the various problems they pose. Average size of 50 eggs 26.9 x 22.8 mm. (Baker).

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

Fledgling (at time of leaving nest) was rufous, with pale bars. Crest developed at c. 5 weeks; moulted gradually into adult plumage at 3 months old (Osmaston, JBNHS 34: 361).

A fledgling in the Brit. Mus. collection from Assam has upperparts dark brown, with pale tips to the feathers; white below (David Lack, *in epist.*).

CUCKOOS

195

from west of a diagonal line from slightly south of Bombay (Maharashtra) to Darbhanga dist. (N. Bihar). A specimen collected in Mysore during November (SA) with a large wing (148 mm.) and excessive body-fat could well be a straggler of this form preparing for belated emigration. East of this line there is a paucity of definitive records and a confusing intermingling during the rainy season with the resident southern population (571). Sight records dubious since the two races cannot be told apart in the field. Affects open well-wooded country, gardens and groves, even within the precincts of towns and villages, and the neighbourhood of cultivation. Also stunted jungle in semi-desert areas.

Extralimital. Putatively Africa south of the Sahara in winter.

MIGRATION. No ringing data, and evidence of migration to and from Africa as yet only circumstantial and largely conjectural. For a discussion of Indian evidence see Whistler, H., 'The Migration of the Pied Crested Cuckoo', JBNHS 33 (1): 136-46, 1928, and E. Ghas Survey Report, *ibid.* 37: 522-3, 1934; of African, Friedmann, H., 1948, *The Parasitic Cuckoos of Africa*: 19, 23, *passim*. Route of migration unknown and enigmatical. Only odd specimens have been obtained in SW. Arabia in March, April, and May presumably on passage (to India?) but no mass movement observed. 'Occurs rarely during autumn migration, August and September' in Kohat and Kurram Valley, NW. Pakistan (Whitehead). A specimen (straggler?) obtained by the first Mt Everest Expedition at Tingri, Tibet (28°33' N., 86°40' E.) at c. 4270 metres altitude (Wollaston & Kinnear, 1922, *Ibis*: 504) and another by M. Babault at Rahla near the Rotang Pass in Kulu (Himachal Pradesh) at c. 3800 m. on 28 June, the latter a male with testes in breeding condition!

x c. 1/2

GENERAL HABITS. Largely arboreal and insectivorous, feeding up in trees but commonly also descending into low bushes and even to the ground, hopping about in search of food. In many areas arrives overnight with almost clockwork regularity, heralding the monsoon, in the last week of May or early June, proclaiming its advent unmistakably by loud metallic calls. At first the birds are usually seen in loose parties of 5 or 6 chasing each other about from tree to tree (territorial or sexual rivalry?) calling noisily and evidently

CUCULIFORMES

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂ ♀	157-166	c. 24-25 (from feathers)	c. 27-28	231-245 mm. (Baker)
Whistler gives for 2 ♀ ♀ from Ceylon	153-158	30-32 (from skull)	27-28	217-222 mm.

Weight 600? 61-75 (av. 70) gm. — SA.

COLOURS OF BARE PARTS. Iris pale reddish brown. Bill black, base of lower mandible generally paler and yellowish; angle of gape and mouth salmon-pink. Legs and feet plumbeous or slaty brown (Baker).

CLAMATOR JACOBINUS (Boddaert)

Key to the Subspecies

- Larger; wing over 144 mm. *C. j. serratus*
- Smaller; wing under 144 mm. *C. j. jacobinus*

570. Pied Crested Cuckoo. *Clamator jacobinus serratus* (Spartman)

Cuculus serratus Spartman, 1786, Mus. Carls., fasc. 1, no. 3 and pl. (Cape of Good Hope = Cape Peninsula, Cape Province, S. Africa)

Cuculus pica Hemprich & Ehrenberg, 1833, Symb. Phys., Aves, sig. r. note 2 (Ambukohl, Dongola)

Baker, FBI No. 1472, Vol. 4: 167

LOCAL NAMES. Pāpiya, Kālā pāpiya, Chatak (Hindi); Hōr kīk (Kashmir); Kālā bulbul, Shāh bulbul (Bengal); Chāllak (Marathi).

SIZE. Myna ± with a much longer tail. Overall length c. 33 cm. (13 in.).

FIELD CHARACTERS. A slender, long-tailed, crested black and white bird.

Adult. Black above, including prominent pointed bulbul-like crest; white below. A roundish white patch on the black wings, and white tips to the black graduated tail-feathers conspicuous in flight. Sexes alike.

Young (immature). Crest less developed; wing-patch

smaller. Black portions of plumage dull and sooty; white portions strongly suffused with fulvous, or fulvous-grey.

STATUS, DISTRIBUTION AND HABITAT. SW. monsoon (breeding) visitor, arriving over most of its Indian range more or less synchronously with the rains (early June) and departing by September-October: West Pakistan and northern India — Sind, Punjab, Gilgit, Kashmir, U.P., Nepal, eastward through Assam, Manipur, and East Pakistan; south in peninsular India to c. 18° N. lat.; plains, and up to c. 2600 m. Not recorded in the Andaman and Nicobar Is. The majority of definite records (specimens) are

x c. 1

196

CUCULIFORMES

establishing themselves. In urban areas invariably set upon and persecuted by the resident House Crows (*Corvus splendens*), and commonly blundering into buildings to escape their tormentors. Courtship displays and chasing commence almost simultaneously with arrival, the male calling lustily and chasing the female about often with tail partly spread and slow deliberate wing-action, as in a pigeon 'clapping'; but breeding biology very imperfectly known. Whether pair bond maintained throughout the season or female promiscuous in her sex relations uncertain.

FOOD. Mainly caterpillars including large hairy ones; also mealy bugs, beetles, ants, terrestrial molluscs (in shady woods in the rains); occasionally green leaves ('possibly of digestive value' — Hingston). Flying termites hawked in air by vertical leaps from a bush-top perch, like bulbul.

VOICE AND CALLS. A loud metallic, rather plaintive but pleasant *piu . . . piu . . .* *pee-pee-piu*, *pee-pee-piu*, and so on, uttered on the wing, especially during courtship chase, and from a perch — in daytime as well as during moonlit nights. Often only the tinkling initial *piu* is repeated, every second or so. Flying juvenile utters a harsh *chū-chū-chū-chū*, and so on, rather reminiscent of the Large Wood Shrike (*Tephrodornis gularis*).

BREEDING. Brood-parasitic mainly on babblers of the *Turdoides* group — most commonly on the lowland and foothills species, e.g. *T. caudatus*, *T. striatus*, and *T. malcolmi*. In the lower Himalayas laughing thrushes (*Garrulax*) are commonly victimized, *G. lineatus* being a popular dupe. In Kashmir the Rufous-backed Shrike (*Lanius schach erythronotus*) is a frequent victim. (For a fuller list of fosterers see Baker, 1942: 195-6.) Season overall June to August, synchronizing with that of the local fosterers. Eggs, unmarked sky-blue varying in depth of tint, usually closely matching those of the fosterer, though in some cases rather larger. The larger size and more rounded oval shape — blunt at both ends — often give the clue. Average of 100 eggs, varying greatly in size, c. 23.9 x 18.6 mm. (Baker). Indistinguishable with certainty from eggs of Hawk-Cuckoo (*Cuculus corvus*) both of which sometimes found together in the same nest. Incubation period undetermined, but believed to be shorter than that of fosterer. Usually only a single cuckoo fledgling (rarely 2) is found in the fosterers' nest or being fed by them outside, which makes it evident that the impostor somehow disposes of the rightful eggs or hatchlings to monopolize the food brought by the parents. A more definitive study is called for.

Has been recorded as 'often feeding fully fledged young of its own species' (E. H. N. Gill). This observation may actually represent courtship feeding of female cuckoo by male and needs critical verification.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit. This migratory race is clinically larger than nominate *jacobinus*; there is no difference in the plumage, and borderline examples are impossible to assign satisfactorily.

MEASUREMENTS. Birds from NW. India (Kashmir, Punjab, U.P.)

	Wing	Bill	Tail
12 ♂ ♂	146-155	25-28 (from skull)	158-176 mm.

Clamator jacobinus taprobanus Hartert, 1915, Nov. Zool. 22: 254 (Northwestern Ceylon) Baker, FBI No. 1473, Vol. 4: 169
Plate 52, fig. 2

LOCAL NAMES. *Kendé kōhā* (Sinhala); *Kendé kūyil* (Tamil); *Gola kōkila*, *Tangada gorankah* (Telugu); *Erattāttalachi kūyil* (Malayalam).

SIZE. Myna \pm , with a much longer tail. Overall length c. 33 cm. (13 in.).

FIELD CHARACTERS. As of 570; a slender, long-tailed, crested, black and white cuckoo. A roundish white patch on the wings, and white tips to tail-feathers conspicuous in flight. Sexes alike.

Young (immature). Crest less well-developed; wing-patch smaller; black portions of plumage dull and sooty; white portions strongly suffused with fulvous or fulvous-grey.

STATUS, DISTRIBUTION AND HABITAT. Resident; Ceylon and peninsular India chiefly south of c. 15°N. lat. — Mysore, Tamil Nadu, Kerala. Disperses widely in the rainy season (SW. monsoon, May/June to September/October), then intermingling with the migratory population (*serratus*) in Andhra Pradesh, Madhya Pradesh and possibly elsewhere. Affects lightly wooded country in dry- and moist-deciduous biotope, lowlands and hills: up to c. 1300 metres in Ceylon (Uva), and to c. 2000 m. in south India (Nilgiris etc.).

GENERAL HABITS, FOOD, VOICE AND CALLS. Not different from 570, q.v., except that its rainy-season migrations and dispersal are restricted to within our limits; but no ringing or other precise data.

BREEDING. Brood-parasitic, like the migrant form, on babblers of the *Turdoides* group, the species most commonly victimized being *T. caudatus*, *T. striatus*, *T. malcolmi*, and *T. subrufus* in the plains, and the laughing thrush *Garrulax cashinians* in the Nilgiri Hills. In Ceylon the local common babbler, *T. affinis taprobanus*, is the chief fosterer. Season, practically the whole year coincidentally with the fosterers', but mainly June to September in peninsular India, February to May in Ceylon. Eggs, beautiful glossy turquoise-blue as in 570, as a rule matching the eggs of the dupes closely; usually distinguishable from them only by their blunter more oval shape. Average size slightly smaller than in *serratus*. Breeding biology as far as known, same as in the migrant form.

MUSEUM DIAGNOSIS. Identical with *C. j. serratus* except for somewhat smaller size clinically. Borderline examples impossible to assign satisfactorily.

MEASUREMENTS. Specimens from Ceylon and Kerala:

	Wing	Bill (from skull)	Tail
16 ♂ ♀	136-144	24-27	147-163 mm. (HW)

CUCKOOS

199

Young (immature), brown above rufous below broadly streaked (not barred) with blackish.

Both adults and young deceptively hawk-like in plumage-pattern at comparable ages, the resemblance to shikra (*Accipiter badius*) further heightened by style of flight.

STATUS, DISTRIBUTION AND HABITAT. Breeds in the Himalayas between c. 900 and 2700 metres, from West Pakistan (c. Murree in Rawalpindi dist.) eastward through Kashmir, Himachal Pradesh, Garhwal, Kumaon, Nepal, Sikkim, and Bhutan to easternmost NEFA (and beyond); also Naga, Manipur, Khasi, and N. Cachar hills. Affects wooded hillsides and valleys. Migrates southward into the Peninsula in winter, recorded then from Madhya Pradesh, Orissa, Tamil Nadu, Mysore and Kerala. Not Ceylon. Unsupported winter sight records not reliable owing to possibility of confusion with the commoner *Cuculus varius*.

Extralimital. From Szechuan and the lower Yangtse valley south to the hills of Burma, Thailand and South Vietnam; partially resident, but migratory in China. In winter Malay Peninsula, Sumatra, Borneo, Java, the Philippines, and Celebes (Sulawesi) — Peters.

GENERAL HABITS. Chiefly arboreal keeping singly to the foliage canopy of forest trees. Drops suddenly out of one and flies swiftly to another, threading its way deftly through the trunks — a few rapid wing-strokes followed by a glide, very like a hawk. The shikra-like plumage and flight, together with the bird's habit of sweeping upward into the branches before settling, are sufficiently convincing to cause a flutter among small birds each time the mimic is on the move. Mostly silent in its winter quarters, but extremely vocal in spring and summer on its Himalayan breeding grounds.

FOOD. Predominantly caterpillars, including large hairy ones; also beetles, bugs, crickets, grasshoppers and hoppers of locusts, ants and spiders.

VOICE AND CALLS. A loud, shrill, insistent screaming whistle, rather musical and even pleasant in small doses: *pipēēēē*, *pipēēēē* or just *pipēē*, *pipēē*, etc. (accent on second syllable) shrieked with monotonous persistency in runs of 5 or 6, usually rising in scale to frantic pitch and breaking off abruptly — presently to commence all over again. The birds call chiefly in the mornings and at sunset, often continuing far into the night and even throughout moonlit nights. Particularly vocal in cloudy overcast weather.

BREEDING. Brood-parasitic chiefly on laughing thrushes (*Garrulax*) and also on a miscellaneous lot of smaller birds of which the Large Spiderhunter (*Arachnothera magna*) and Nepal Shortwing (*Brachypteryx l. ripalensis*) are described as the most popular victims. Season. In the Western Himalayas eggs have been taken between 15 June and end July; in Assam April to end June coinciding with the laying of its accustomed hosts. Evidently two types of eggs have been evolved: (1) turquoise blue, matching closely those of laughing thrushes, (2) brown, approximating the eggs of spiderhunters, shortwings, etc.; in both cases usually distinguishable from the dupes' by larger size and blunt oval shape. Average size of blue eggs c. 30 × 22 mm.; of the brown type c. 26 × 19 mm. (Baker). For a fuller list of fosterers see Baker, 1942: 191-2, and 1906, JBNSHS 17: 364.

No other explanation seems rational for the cuckoo's egg being found in the closed nest of the spiderhunter — attached on the underside of a swaying

198

CUCULIFORMES

Tarsus 25-28 mm. (SA).

Weight 1300 ♂ 50-73 gm. — SA.

COLOURS OF BARE PARTS. As in 570.

Genus CUCULUS Linnaeus

Cuculus Linnaeus, 1758, Syst. Nat., ed. 10, 1: 110. Type, by tautonymy, *Cuculus canorus* Linnaeus (*Cuculus prebinomialis* specific name in synonymy)
Hierococyx S. Müller, 1842, Verh. Nat. Gesch. Ned. Land-en-Volkenk.: 223. Type, by monotypy, *Cuculus fugax* Horsfield

No crest. Bill of moderate size; gape exceptionally large and flexible. Nostrils round. Tarsus partly feathered. Contains both migratory and sedentary forms. In the former, wing long and pointed: 1st primary (as.) = two-thirds length of 3rd, which is longest. Tip of closed wing exceeds tips of secondaries by nearly half its total length. In the non-migratory forms (formerly *Hierococyx*) wing shorter and more rounded: 3rd or 4th primary longest. Tip of closed wing exceeds tips of secondaries by only one-fifth to one-third its total length. Tail long, yet shorter than wing, well graduated; upper tail-coverts very long, somewhat pointed, reaching to about middle of tail.

Plumage in adults chiefly ashy grey or ashy brown above, barred below — remarkably accipitrine in pattern. Young pass through more than one phase before assuming adult plumage. Sexes alike or nearly so.

572. Large Hawk-Cuckoo. *Cuculus sparveroides sparveroides* Vigors

Cuculus sparveroides Vigors, 1832 (1831), Proc. Zool. Soc. London 1: 173 (Himalayas)
Baker, FBI No. 1457, Vol. 4: 146
Plate 51, fig. 1

LOCAL NAMES. *Bādā bhārāo* (Nepal); *Nimbin pīyal* (Lepcha).

SIZE. House Crow —; slimmer. Length c. 38 cm. (c. 15 in.).

FIELD CHARACTERS. Adult. Above, crown, nape and sides of neck ashy grey passing into rich ashy brown of rest of upperparts. Tail above brown, banded with blackish and tipped with white or rufous-white. Below, throat white streaked with ashy and rufous, passing into more rufous upper breast and then into the white underparts suffused with rufous and cross-banded with brown. Sexes alike.

200

CUCULIFORMES

banana leaf, and with only a narrow semicircular entrance-hole — than that the egg is initially laid elsewhere and then transferred to the nest with the cuckoo's bill. However, the actual process has never been observed.

MUSEUM DIAGNOSIS. See Key; for details of plumage Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	213-236	28-30	c. 25-27	175-220 mm. (SA, BB, HW)

Weight 2 ♂ 116, 131 gm. (GD).

COLOURS OF BARE PARTS. Iris [creamy khaki to] orange-yellow; edges of eyelids lemon-yellow. Bill: upper mandible dark horny, paler on the tip, lower mandible greenish slaty, dusky on sides of anterior half and on tip; gape dull lemon-yellow. Legs and feet lemon-yellow; claws pale yellowish horny; pads dirty lemon-yellow (Biswas).

CUCULUS VARIUS Vahl

573. Common Hawk-Cuckoo or Brainfever Bird. *Cuculus varius varius* Vahl

Cuculus varius Vahl, 1797, Skriv. Naturhist.-Selsk., Kjøbenhavn 4 (1): 60
(Tranquebar)
Baker, FBI No. 1458, Vol. 4: 148
Plate 51, fig. 3

LOCAL NAMES. *Kepak*, *Upek*, *Pāpiya* (Hindi); *Bhārāo* (Sinhālikars, Bihār); *Chokgallo* (Bengal); *Kūtti pitta* (Telugu); *Zakkhat* (Deccan); *Bāppāyo* (Gujarati); *Shikrā kūyil* (Malayalam).

SIZE. Pigeon \pm , slenderer and with proportionately longer tail. Overall length c. 34 cm. (13½ in.).

FIELD CHARACTERS. A shikra-like cuckoo.

Adult. Above ashy grey, tail tipped rufescent and with 4 or 5 whitish and black bars, the terminal one broadest. Below, white suffused with rufous and ashy on breast and barred with brownish on abdomen and flanks. Sexes alike.

Young (immature).

Above, brown, barred with dull rufous; barring in tail rufous and black instead of whitish and black. Below, buffy white broadly streaked (not barred) with blackish brown drops. Thus juvenile plumage also very like immature shikra hawk.

CUCKOOS

201

STATUS, DISTRIBUTION and HABITAT. Resident, but subject to local migratory and nomadic movements especially during the rainy season. Apt to be overlooked in winter when it is silent. Occupies a lower zone in the Himalayas than *sparveroides*, normally not above c. 1000 m. Widespread over the entire subcontinent from Punjab (Rawalpindi dist.) eastward through Nepal, Sikkim, Bhutan, Assam, and East Pakistan; southward to Kanyakumari, and straggling into Ceylon. A rains straggler in Rajasthan and the semi-desert portions of Gujarat. Affects well-wooded deciduous and semi-evergreen biotope, hill and plain; partial to gardens, groves of trees, mango topes, etc. in the neighbourhood of cultivation and human habitations.

GENERAL HABITS. Arboreal, seldom if ever descending to the ground; usually keeps singly or in pairs to the foliage canopy of trees. Silent in winter and then very liable to be passed over as absent. With approach of the hot weather (c. March in the Himalayan foothills and duns) wakes increasingly vocal to a peak in about May, thereafter gradually reverting to silence by August/September. Exasperatingly obstreperous in the plains during the rainy season, calling monotonously and often almost incessantly throughout the day and during moonlit nights. Flight and movements deceptively hawk-like, as in 572, q.v.

FOOD. Principally caterpillars and cutworms; also grasshoppers, locust hoppers, beetles, bugs, ants, winged termites and spiders; wild figs (*Ficus* spp.); occasionally lizards. Among stomach contents the following insects have been frequently identified: *Brachytrypes achatus*, *Gryllos melanoccephalus*, *Schizodactylus monstrosus*, *Gryllotalpa africana*, *Dysdercus cingulatus*, *Amnomala varians*, cutworms (*Agrotis* spp.), hairy caterpillars (*Lymantriid*?), and ants (*Oecophylla*, *Camponotus*).

VOICE and CALLS. A loud shrieking high-pitched *wee-piehit*, aptly syllabified as *brainf-er* (accent on *fe*), repeated *ad nauseam* in runs of 4 to 6 crescendo calls, mounting progressively to frantic shrillness and breaking off abruptly, to commence all over again after a minute or two. On cloudy overcast days and moonlit nights during the peak period the screaming is almost non-stop. A 'trilling note' in addition to the *brainf-er* calls has been recorded, without details (Basil-Edwards, 1926, JBNHS 31: 569). 'Female has a harsh grating call quite different from male's' (W. E. Brooks, 1878, SF 7: 265).

When clamouring to be fed by foster parents (Jungle Babbler), a stub-tailed fledgling uttered a harsh single screech like a Roseringed Parakeet's. While accompanying a flock of these babblers, it gave a grating *kē-kē* from time to time, a very passable imitation of the fosterers' but in somewhat higher key (SA).

BREEDING. Brood-parasitic chiefly on babblers of the *Turdoides* group, mostly the Jungle Babbler (*T. striatus*). In the Himalayan foothills and the Nilgiris, laughing thrushes (*Garrulax*) are commonly victimized. For a fuller list of hosts see Baker, 1942: 192-3. Season, variable, coinciding with the laying season of the local hosts, chiefly between March and June, but also in later months. Eggs, beautiful glossy turquoise-blue, often indistinguishable from those of its babbler hosts except by somewhat blunter oval shape. They are hard to tell from eggs of Pied Crested Cuckoo, both sometimes found in the same nest, but are somewhat more elliptical. Size very variable,

575. Hodgson's Hawk-Cuckoo. *Cuculus fugax nivicolor* Blyth

Cuculus nivicolor Blyth, 1843, Jour. Asiat. Soc. Bengal 12(2): 943 (Nepal)
Baker, FBI No. 1460, Vol. 4: 151
Plate 51, fig. 2

LOCAL NAME. Ding-pit (Lepcha).

SIZE. Pigeon —; slenderer. Length c. 29 cm. (11½ in.).

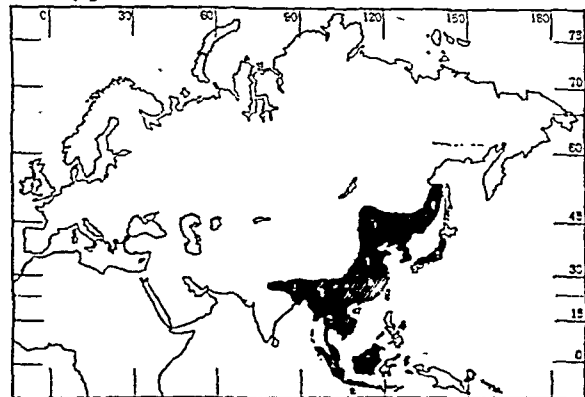

FIELD CHARACTERS. A slender grey cuckoo with unbarred rufous underparts.

Adult. Above, including sides of head and hindneck uniform slaty grey; wings brownish; tail alternately banded grey and black, tipped with rufous. Below, chin grey; throat and foreneck white sparsely streaked with grey; rest of underparts largely rufous; vent and under tail-coverts white. Sexes alike.

Young (immature). Above, brown, the feathers edged and barred with rufous; tail as in adult. Below, white, rather rufous on breast, closely barred and streaked with blackish (Baker).¹

STATUS, DISTRIBUTION and HABITAT. Predominantly a hill species like *C. sparveroides*. Mainly resident, but subject to local and altitudinal migration, occasionally (or regularly?) wandering considerable distances possibly

Cuculus fugax

1 *C. f. hyperythrus* (RE).
2 *C. f. fugax* (RE). 3 *C. f. nivicolor*. 4 *C. f. pectoralis* (RE).

even extraliminally. The lower Himalayas in Nepal, Sikkim, Bhutan and eastward through NEFA. Assam hills south of Brahmaputra river, Nagaland, Manipur, East Pakistan. Affects wooded country in deciduous,

¹ This needs confirming; see Key to the Species. Fledglings and immatures of parasitic cuckoos are notoriously difficult to identify with certainty chiefly owing to lack of definitive clues to their parentage. Hence the confusion and contradictions in published descriptions.

202

CUCULIFORMES

averaging c. 26 × 20 mm. (Baker). A young cuckoo accompanying a flock of Jungle Babblers will be fed by its particular foster parents from time to time, and occasionally even by other members of the sisterhood. Yet paradoxically enough each time the fledgling flies there will be a nervous stir among the flock, some members promptly giving the 'ware hawk' alarm; they will, however, tolerate the same impostor complacently and resume tending it the moment it has settled again and is hopping about in their midst greedily begging food!

MUSEUM DIAGNOSIS. As in 572, wing more rounded than in *Caculus* species; primaries exceeding secondaries in closed wing by only one-fifth to one-third the total length. For details of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	193-213	25-31	21-23	157-183 mm.
♀♀	192-207	26-29	23-26	156-180 mm. (SA, BB)

Weight 1 ♀, very fat, 104 gm. (GD).

COLOURS OF BARE PARTS. Adult. Iris greyish yellow or yellowish buff; rim round eyes (eyelids) and gape lemon-yellow. Bill yellowish green, black on culmen and tips; mouth pink and yellow. Legs, feet, and claws bright chrome yellow. Fledgling (just ex nest). Iris greyish brown; eyelids greenish yellow. Bill pale brownish yellow; gape and mouth yellow (like young babbler's). Legs, feet, and claws pale yellow.

574. Ceylon Hawk-Cuckoo. *Cuculus varius ceticus* (Phillips)

Hierocorys varius ceticus Phillips, 1949, Bull. Brit. Orn. Cl. 69: 56 (Caledonia Estate, 4000 ft, Lindula, Dimbula, Ceylon)
Not in Baker

LOCAL NAMES. Kāśā (Sinhala); Kūyil, Kūnil (Tamil).

SIZE. Pigeon ±, slenderer and with proportionately longer tail. Overall length c. 34 cm. (13½ in.).

FIELD CHARACTERS. An ashy grey shikra-like cuckoo, indistinguishable from 573 (q.v.) except in the hand. See Key and Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Race peculiar to Ceylon. Resident; moderately plentiful locally in the hills above c. 650 m., especially in the Central Province, possibly visiting the Wet zone when not breeding. Affects well-wooded country such as tea estates and gardens.

It is probable that the nominate race also visits the island from the Indian mainland.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 573, q.v.

BREEDING. Brood-parasitic on babblers of the *Turdoides* group. Season, January to April and probably later. Eggs not yet taken but doubtless the same as in Indian birds, glossy turquoise-blue closely matching those of its normal hosts.

MUSEUM DIAGNOSIS. Differs from nominate *varius* only in being somewhat darker overall in a comparative series.

MEASUREMENTS and COLOURS OF BARE PARTS as in 573.

204

CUCULIFORMES

semi-evergreen and evergreen biotopes, between c. 600 and 1800 m. altitude. Keeps chiefly to bushes and the understorey.

Extralimital. Breeds also in Burma, Thailand, Indochinese countries, and S. China. Winter visitor in part (?) to the Malay Peninsula, Sumatra, Java, etc.

GENERAL HABITS. Apparently nowhere common. Little specifically known as the bird is usually very silent and skulking, thus doubtless often overlooked.

FOOD. Caterpillars, cicadas, and other insects. Also a quantity of fruits and berries.

VOICE and CALLS. Described as a sibilant, insistent *gee-whizz*, *gee-whizz* repeated up to 20 times; vaguely reminiscent of the shrill shrieking of *C. sparveroides* but the call is even thinner and shriller and quite distinct from any other cuckoo's. In breeding season often calls throughout the night.

BREEDING. Brood-parasitic apparently chiefly on flycatchers and shortwings (Muscicapinae and Turdinae), but the breeding biology is practically unknown. The only oviduct egg ever taken was from a nest by Baker as late as 14 September. A putative egg was taken from a nest by Baker as late as 14 September. The oviduct egg was broad oval in shape with unglossed but smooth and firm shell, uniform olive-brown in colour with an indistinct ring of darker shade round the larger end. It measured 22.6 × 16.3 mm.

Baker (1942: 198) gives the average of 73 eggs from all fosterers' nests as 24.44 × 15.84 mm.

MUSEUM DIAGNOSIS. Underparts unbarred. Penultimate broad black band in tail followed by a narrow band of rufous grey or grey-brown and then a narrow band of black.

Nestling. Feathers of head and upper back more definitely edged with pale rufous. Below, chin, throat, and upper breast dark brown narrowly edged with rufous (Baker).

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂♂	178-182	19-20	c. 23-24	141-144 mm.

COLOURS OF BARE PARTS. Iris orange to vermilion; eyelids yellow. Bill horny black, the base and nearly all the lower mandible pale greenish horny; gape more yellow. Legs, feet, and claws bright yellow (Baker).

576. Indian Cuckoo. *Cuculus micropterus micropterus* Gould

Cuculus micropterus Gould, 1837, Proc. Zool. Soc. London: 137 (Himalayas)
Cuculus micropterus fatidicus Koelz, 1954, Contrib. Inst. Regional Exploration, No. 24 (Laikul, N. Cachar)
Baker, FBI No. 1456, Vol. 4: 144
Plate 51, fig. 10

LOCAL NAMES. *Bru-kath-kas* (Bengal); *Kyphal pilla* (U.P., Mussooree); *K pilla* (Himachal Pradesh); *Kyd-pilla-pillo* (Nepal); *Tāpō* (Lepcha); *Kāng kō* (Bhutan); *Kōpōo* (Hunza).

SIZE. Pigeon ±, slenderer and with proportionately longer tail. Overall length c. 33 cm. (13 in.).

CUCKOOS

205

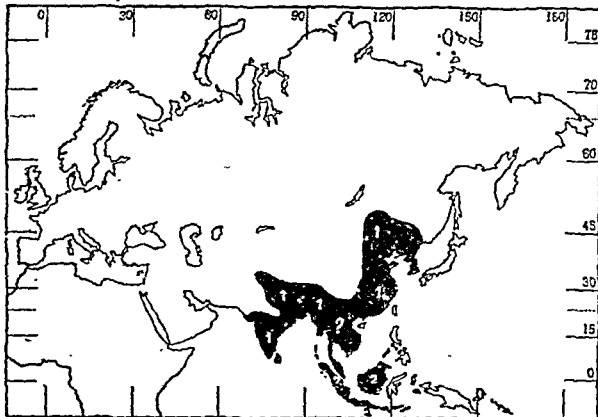

FIELD CHARACTERS. Very similar to the European and Himalayan Cuckoos (578, 580) q.v. Dark slaty grey above with a brownish tinge; pale ashy and white below cross-banded with widely spaced broad black bands. Readily distinguished from them also by broad black subterminal band on tail, more rounded and quicker flapping wings, and most conclusively by the unmistakable 4-syllabled call—a musical *kyphāl-pāka* or *crossword-puzzle*, repeated *ad nauseam*.

Female differs in having the pale grey throat and breast browner and with a rufous tinge.

Young (immature). Above, barred with white or rufous white on head and neck; broadly tipped with rufous and white elsewhere. Below, pale buff broadly barred with black. Tail as in adult but more rufous and more numerous barred.

STATUS, DISTRIBUTION and HABITAT. Occurs variously as resident, nomadic or seasonal visitor (rains and winter) in the lower Himalayas from Kashmir eastward through NEFA (including Nepal, Sikkim, and Bhutan), and southward throughout the subcontinent excepting the arid portions of W. Pakistan, Rajasthan, Kutch, Saurashtra and N. Gujarat. Occurs also in E. Pakistan ('excessively common in Chittagong'—Bates),

Cuculus micropterus

Overall range 1 *C. m. micropterus*. 2 *C. m. canorus* (RE).

Ceylon, and the Andaman and Nicobar islands. Affects fairly wooded country in deciduous and evergreen biotopes up to c. 2300 m. altitude, and rarely even to c. 2800 m. In Nepal 'very common [in summer] up to 10,000 ft [c. 3300 m.] and at 12,000 ft [c. 3700 m.]' (Desirée Proud). Silent over most of its range between August/September and March/April, then

CUCKOOS

207

period of the cuckoo's eggs is c. 12 days, i.e. 2 or 3 days shorter than the shrikes'. [For an excellent recent account and details see Neufeldt, I., 1966, 'Life History of the Indian Cuckoo (*Cuculus micropterus micropterus* Gould) in the Soviet Union', JBNHS 63: 399-419.]

MUSEUM DIAGNOSIS. See Key.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	190-207	28-32	c. 20-21	142-161 mm. (SA, HW, BB)

A pair from Ceylon are smaller, and more material may reveal a discrete insular population there. They measure (from feathers)

♂	187.5	24	148 mm.
♀	185.5	21.5	143 mm.

Weight 1 ♂ 128 gm. (winter)—SA.

COLOURS OF BARE PARTS. Iris brown to reddish brown; rim round eye (eyelids) bright lemon-yellow. Bill: upper mandible horny brown, lower greenish brown, yellow at chin and gape; mouth yellowish pink. Legs and feet yellow; claws horny brown.

CUCULUS CANORUS Linnaeus

Key to the Subspecies

	Page

C Colour of upper- and underparts intermediate..... <i>C. c. canorus</i>	208

577. Asiatic Cuckoo. *Cuculus canorus subtelephonus* Zarudny

Cuculus canorus subtelephonus Zarudny, 1914, Orn. Mitt. 5: 108, 115 (Turkistan) Not in Baker, FBI

LOCAL NAMES. Not recorded.

SIZE. Pigeon ±; slenderer. Length c. 33 cm. (13 in.).

FIELD CHARACTERS. As for 578, q.v. See Key and Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Evidently occurs in Baluchistan (breeding or on passage?) but available material insufficient to clarify the status (Ticehurst, 1927, JBNHS 31: 881). It is the breeding bird of Iran (west to the Caspian Sea), and a passage migrant in Iraq and 'Persian Baluchistan' (SE. Iran). May also occur in northeastern NEFA.

Extralimital. 'Transcaspia, Russian Turkistan and western Chinese Turkistan; recorded from the western slopes of the Ala Shan in extreme southern Mongolia, from the valley of the upper Huang ho and from a northern tributary of the Mekong in SE. Tibet. Winters in East Africa' (Peters).

CUCULIFORMES

206

likely to be overlooked and assumed absent; but most vociferous in Ceylon between c. January and May, especially during March and April.

Extralimital. Breeds also in Burma, Thailand, Malay Peninsula, S. China, Korea, and U.S.S.R. (lower Amur region). Winters in the Philippines and Indonesian islands.

MIGRATION. No ringing data. Whether, as suspected, it performs regular extralimital migrations in addition to local seasonal movements not proven.

GENERAL HABITS. Chiefly arboreal, keeping singly to tree-tops and canopy foliage or seen flying about hawk-like above the forest canopy. In northern and most of peninsular India very vocal when breeding, mainly between mid March and early August. Especially obstreperous in the early hours before dawn and till about 9 a.m., and again from about dusk till far into or even throughout the night, particularly if moonlit. Noisy during daytime in cloudy overcast weather. Also calls on the wing during courtship chase of female.

FOOD. Hairy and other caterpillars, and various insects. Sometimes descends to the ground, hopping about awkwardly to pick them up from among the littered leaves. Among stomach contents of specimens, *Gryllotalpa africana*, *Sphex lobatus*, and other hymenopteran remains have been specifically identified.

VOICE and CALLS. Very distinctive and diagnostic. The 'song' is a loud and far-carrying 4-syllabled fluty whistle capable of a wide range of local onomatopoeic renderings, *Kyphāl-pāka*, *Bo-kōtāko*, *Orange-peloe*, *Crossword puzzle*, *What's your trouble*, being some. The key and timbre is often individually variable. The calls may be iterated continuously every two seconds or so for 5 minutes or more at a stretch, monotonously and with unvarying cadence, in intermittent runs for hours on end; timed at 23 calls per minute and 43 in two minutes. A warbling call aptly described as 'water-bubbling' uttered by the female, chiefly in flight, is almost identical with similar calls of female *C. canorus* and *C. saturatus*. There is also a rapid twice- or thrice-repeated *quik* occasionally given by the female (?). While serenading a nearby female the wings are drooped, the tail often spread out and erected, and the bird pivots from side to side.

BREEDING. Brood-parasitic, reportedly in the main on the drongos *Dicurus adsimilis* and *D. leucophaeus*. Other species in whose nests putative eggs of this cuckoo are claimed to have been found, or which have been observed feeding its young, are Paradise Flycatcher (*Terpsiphone paradisi*), Streaked Spiderhunter (*Arachnothera magna*), and Ceylon Blackheaded Oriole (*Oriolus x. ceylonensis*). However, the available data on the breeding biology of this and other parasitic cuckoos in India are, by and large, meagre, and of dubious authenticity. Most accounts are vague, largely conjectural and often contradictory. The whole subject calls for a more methodical *de novo* re-investigation. Oviduct eggs from females of this species are reported as of two types: (1) whitish with reddish brown stippling closely matching drongos' eggs, and (2) pale greyish blue, resembling the eggs of some of the Turdinae. They measure c. 25 × 19 mm.

In Amurland (U.S.S.R.) whence we possess fuller information, the principal fosterer is the Amur Brown Shrike (*Lanius cristatus confusus* Stegmann) whose eggs closely match those of this cuckoo. The incubation

CUCULIFORMES

208

GENERAL HABITS, FOOD, VOICE and CALLS. As in 578.

BREEDING. Extralimital. May possibly breed in Baluchistan, but unknown with certainty.

MUSEUM DIAGNOSIS. Differs from both 578 and 579 in being much paler coloured on head, neck, and breast, and in having fewer, finer, and less blackish cross-bars on the underparts; also in being smaller, with wings sometimes down to c. 180 mm.

MEASUREMENTS

Wing ♂ 204-220, ♀ 184-216 mm. (Portenko, 1931, Mitt. Zool. Mus. Berlin 17: 417-22).

COLOURS OF BARE PARTS. As in 578.

578. Cuckoo. *Cuculus canorus canorus* Linnaeus

Cuculus canorus Linnaeus, 1758, Syst. Nat., ed. 10, 1: 110

(Europa = Sweden, ex Fn. Succ.)

Cuculus telephonus Heine, 1863, Jour. f. Orn. 11: 352 (Japan)

Baker, FBI No. 1451, Vol. 4: 135

Plate 51, fig. 11

LOCAL NAMES. *Phūphū*, *Kūpūh* (Kumaon); *Kūkhū* (Lepcha); *Akkū* (Bhutea); *Hār kūk*, *Shākūk*, *Kikū*, *Kūkil* (Kashmir).

SIZE. Pigeon ±; slenderer. Length c. 33 cm. (13 in.).

FIELD CHARACTERS. General effect, shape of wings and manner of flight reminiscent of sparrow-hawk. Unmistakable oft-repeated *cūck-koo* call.

Male (adult). Above, dark ashy grey; tail blackish brown, spotted and tipped with white and without the subterminal black band of Indian Cuckoo. Below, chin, foreneck and breast pale ashy; rest of underparts white, narrowly cross-banded with blackish.

Adult Female has a rufous tinge on upper breast and sometimes on throat and sides of neck. Also has a hepatic phase with the entire upperparts barred chestnut and blackish brown. Below, as in normal female but chin, throat and upper breast barred pale chestnut and blackish, and lower breast and abdomen tinged with rufous.

Juvenile hepatic female duller, with white fringes to feathers of upperparts. Fledgeling distinguished from fledgelings of *C. saturatus* and *C. poliocephalus* by almost invariable presence of a conspicuous white nuchal spot.

STATUS, DISTRIBUTION and HABITAT. Resident, nomadic, and seasonal local migrant—possibly also translimital as in the Palaearctic Region.¹ Common in the Himalayas in summer, arriving c. mid March and leaving again in July/August, from the Afghan frontier through Gilgit, Kashmir (the commonest cuckoo), Ladakh, Himachal Pradesh, Garhwal, Kumaon, and Nepal to Sikkim (?), breeding at between c. 600 and 4100 metres altitude. Highest occurrence recorded at Shaksam, Kashmir, 5250 m.

¹ On winter status and probable winter quarters see Deshayes, M., 1974, JBNHS 71: 145-6.

× c. 1

Between early August and mid March both this race and the next (*C. c. bakeri*) are dispersed practically throughout the Peninsula south to Kerala. Rare vagrant in Ceylon and Andaman Is. Maldives Is. (sight record, Phillips, JBNHS 60: 579). There is good circumstantial evidence (persistent 'singing' by males, enlarged gonads of dissected specimens, and fledglings being tended by fosterers) that some birds also breed in the Peninsula, e.g. in Madhya Pradesh (Mhow, Saugor, Kamptee), Maharashtra (Chikaldia), Gujarat (Mt Abu, Deesa, Kutch), Chota Nagpur, and possibly in the south Indian hills and elsewhere between May and July/August, during the SW. monsoon. However, the ecology and breeding biology of Indian parasitic cuckoos, and their varying status from locality to locality and season to season, are as yet very imperfectly known. Their unobtrusive habits, the superficial resemblance of many species to one another, and likelihood of misidentification particularly when not calling, renders definitive observations difficult and often unreliable. Many of the mysteries can only be solved through large-scale ringing of fledgling cuckoos.

Extralimital. Breeds in Europe and Asia from the British Isles eastward through Scandinavia and N. Russia, to NE. Siberia and Kamchatka; southward to the Pyrenees, the Mediterranean, Asia Minor and N. Iran; east to Manchuria, Korea, Japan, and the Kurile Is. Winters in Africa, Malaysia to New Guinea.

GENERAL HABITS. Chiefly arboreal, keeping singly to leafy tree-tops or seen flying about hawk-like above the canopy in well-wooded country. Occasionally descends to the ground and walks about to pick caterpillars and other insects from amongst littered leaves, or to investigate eligible nests of pipits and chats for laying in. Mostly silent and unobtrusive in non-breeding season, then apt to be easily overlooked. Very obstreperous when breeding, the males singing lustily from tree-tops all day (chiefly early morning and around sunset) and often far into or even throughout the night. While calling under excitement of a female's proximity the throat is inflated or 'goitred' out like a pigeon, the body held horizontal with wings drooping at the sides, tail spread out and partly cocked (sometimes vertical), the bird lightly oscillating or pivoting from side to side. At other times calls with tail depressed, rump-feathers fluffed out, and wings drooping at the sides. The call is also uttered on the wing during courtship chase of a female, or while in pursuit of an interloping rival.

FOOD. Insects and their larvae, particularly hairy caterpillars. The cicada *Geana sulphurea* Hope largely eaten in E. Himalayas (Stevens).

VOICE AND CALLS. 'Song' of the male, the well-known *cuck-koo* occasionally varied to *cuck-cuck-koo*, repeated persistently in long unbroken runs (once 170 counted) at the rate of about one call per second. These are interlarded with hoarse wheezy chuckles. The tempo of the calls varies with the degree of the prevailing excitement at the proximity of a female. The female utters a series of 'water-bubbling' notes *quik-quik quik-quik*, sometimes repeated rather slowly, and also an occasional harsh chuckle like the male's. Her bubbling notes are almost identical with those of *C. saturatus* and *C. micropterus*, and females of the three species cannot be satisfactorily differentiated by their calls.

FIELD CHARACTERS. As of 578, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Not properly worked out. Breeds in the Assam hills south of Brahmaputra river — Garo, Khasi, Jaintia, Cachar, etc. — probably also in Nagaland, Manipur, Mizo and East Pakistan. Occurs at one season or another (and may breed) in Sikkim, Bhutan (collected by Ludlow up to c. 3300 m. alt. in summer) and NEFA. May occasionally turn up in far-flung parts of the subcontinent, thus Ahmadnagar dist., Maharashtra (Abdulali, 1954, JBNHS 52: 210). Affects well-wooded country, orchards, etc.

Extralimital. 'Breeds from eastern Kokonor and SW. Kansu southward through W. Szechuan and W. Kansu (probably adjacent parts of E. Tibet) to Burma (Pegu Yomas) and the Shan States' (Peters). In winter to the Indochinese countries.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 578, q.v.

BREEDING. As in 578. *Season*, chiefly April/May to June/July. Principal fosterers over most of its range and also in the Khasi Hills, warblers of the genera *Cisticola* and *Sylvia* (= *Prinia*) which build fragile domed nests of grass with a small lateral entrance-hole. Other members of the family Muscipidae, especially chats and small babblers, are also victimized. For method of the cuckoo's laying in domed and even less accessible nests see under 578. Eggs, broad blunt oval, as widely variable in size and coloration as in 578. Average size of 300 eggs 24.2 × 17.9 mm. (Baker).

MUSEUM DIAGNOSIS. Distinguished from nominate *canorus* by darker upperparts, often almost blackish slaty; barring on underparts broader, blacker and further apart. Female differs from male as in 578.

MEASUREMENTS

♂ ♀ Wing 208-240, mostly between 225-235 mm. (Baker). One very small ♀ has wing 198 mm. (Abdulali). Males usually somewhat larger.

COLOURS OF BARE PARTS. As in 578.

580. Himalayan Cuckoo: *Cuculus saturatus saturatus* Blyth

Cuculus saturatus Hodgson = Blyth, 1843, Jour. Asiat. Soc. Bengal 12 (2): 942 (Nepal)

Cuculus opisthus Gould, 1845, Proc. Zool. Soc. London: 18 (Port Essington, Northern Territory)

Baker, FBI No. 1454, Vol. 4: 140

LOCAL NAMES. *Tong ting tyong* (Lepcha); *Daa hoo hoo* (Cachar); *Hoo kaka* (Khasi).

SIZE. Pigeon —; slenderer. Length c. 31 cm. (12 in.).

FIELD CHARACTERS. Very similar to 579 and doubtfully distinguishable from it except by its distinctive 4-noted hoopoe-like call. At rest and on a good view perhaps also by the edge of the wing-shoulder being pure white r. barred brown and white (see Key and Museum Diagnosis). Female sometimes has a hepatic phase as in *C. canorus*.

STATUS, DISTRIBUTION AND HABITAT. Described as 'summer visitor' to the lower Himalayas, but probably resident. Like other Himalayan cuckoos vocal between March/April and July/August mostly when breeding, and much oftener heard than seen. Liable to be overlooked or misidentified in

BREEDING. Brood-parasitic on a wide range of hosts, pipits (Motacillidae), shrikes (Laniidae), but chiefly on babblers, flycatchers, warblers and chats (Muscicapidae). Female believed to be polyandrous or promiscuous in her sex relations. *Season*, March to August synchronizing locally with that of the fosterers. Eggs laid directly into nest of host. In the case of closed or globular nests the cuckoo clings on the outside in acrobatic postures with her vent against the tiny entrance-hole and projects the egg directly into it. In inaccessible nests, such as a chat's in a ground-hollow under a stone, the egg is first laid outside then inserted within with the bill. This process has been observed and authenticated in the case of the Khasi Hills race, *C. c. bakeri* (Livesey, 1937, JBNHS 39: 625-6). Eggs, broad blunt oval, widely variable in size and coloration, usually matching those of the fosterer; ranging from white with reddish brown streaks and stippling to uniform pale blue. Average size of 100 eggs picked at random from a large series 23.6 × 18.1 mm. (Baker). Incubation period also variable, the eggs of the cuckoo usually hatching a day or two earlier than the host's. The young cuckoo in the first 5 or 6 days of hatching possesses a curious sensitive patch or depression on its back, any contact with which produces an impulse to heave upwards. By means of this adaptation the impostor manages to jettison all the rightful hatchlings and unhatched eggs over the rim of the nest or out of the entrance-hole, thereafter monopolizing the attention of the fosterers and the entire food intended for their brood. The young cuckoo thus grows apace, and by the time it leaves the nest it is already several times the bulk and weight of some of the smaller fosterers like pipits and warblers who are often obliged to settle on its back in order to put the food down the cavernous gape of the insatiable monster!

MUSEUM DIAGNOSIS. No subterminal black band on tail; edge of wing mixed white and brown. For distinguishing from *C. c. bakeri* see Key to the Subspecies; for description of plumages, structure (and bionomics) Witherby, 1938, 2: 296-302.

MEASUREMENTS			
	Wing	Bill (from skull)	Tarsus
♂♂	209-243	26-29	c. 21-24
♀♀	213-230	c. 28	c. 23-24
For British examples Witherby gives:			
♂♂	216-228	24-28	18-24
♀♀	200-223	—	—
Weight 1 ♂ 90 gm. (GD).			
COLOURS OF BARE PARTS. Iris pale to deep yellow; eyelid yellow. Bill dark horn brown, paler and yellowish at base and on commissure, orange-yellow at gape. Legs and feet wax yellow; claws horny.			

579. Khasi Hills Cuckoo. *Cuculus canorus bakeri* Hartert

Cuculus canorus bakeri Hartert, 1912, Vög. pal. Fauna 2: 948 (Shillong, Assam)
Baker, FBI No. 1453, Vol. 4: 139

LOCAL NAME. Kākā (Khasi).

SIZE. Pigeon ±; slenderer. Length c. 33 cm. (13 in.).

silent period. Breeds from the Afghan frontier eastward through Gilgit, Kashmir, Ladakh, Himachal Pradesh, Garhwal, Kumaon, Nepal, Sikkim, Bhutan and NEFA between c. 1500 and 3300 m. altitude; also in the Assam hills south of the Brahmaputra river. Has been taken (rarely) in winter in the plains in N. India (Uttar Pradesh, Rajasthan, Bihar, Assam).

Cuculus saturatus

No authentic data for further south; possibly occurs as vagrant but unrecorded owing to difficulty of recognition when not calling. Davison's old record from Wynad, Kerala (SF 10: 359) probably mistaken as shown by Blanford (1893, PZS: 318). Not uncommon in the Andaman and Nicobar Is. 'in summer' (Butler 1899, JBNHS 12: 565). Affects hilly wooded country and orchards.

Extralimital. Burma, Thailand, S. China, Formosa (Taiwan).

GENERAL HABITS AND FOOD. By and large as in 578, q.v.

VOICE AND CALLS. Distinctive and diagnostic: a loud, far-carrying *ūp...ēēp-ēēp-ēēp* or *kūd-kūd-kūd-kūd*, the initial *ūp* a soft undertone audible only at close range. In the distance call confusable with hoopoe's, but characteristically 4-noted against hoopoe's 3. While calling from a tree-top throat inflated or 'goitred' out as in a pigeon, and wings drooped at the sides. Male also emits a medley of hoarse, almost ghoul-like, croaks and chuckles. Calls less persistently than Indian Cuckoo or 578, but at all times of day and night, especially moonlit nights. 'Water-bubbling' notes of female indistinguishable from those of 578, q.v.

BREEDING. Brood-parasitic commonly on flycatcher- and leaf warblers of the genera *Sericornis* and *Phylloscopus*, tiny birds less than one-third its own size; in Kashmir the Large Crowned Leaf Warbler (*Phylloscopus occipitalis*) most frequently victimized. *Season*, principally May-June,

CUCKOOS

213

synchronizing with that of the hosts. Eggs, long ellipses, greatly variable in size, often inconspicuously small for the cuckoo. Coloration also variable, mainly pale skim-milk blue or white with faint minute dark stippling, usually matching the eggs of the host. Average size of 40 eggs c. 20×13.5 mm. (Baker). Fellow-nestlings and unhatched eggs ejected from nest presumably in same way as by 578.

MUSEUM DIAGNOSIS. Similar to 578, q.v., but with the edge of the wing-shoulder pure white, without any brown barring. Black bars on underparts bolder and wider apart. For description of hepatic female, juvenile, and nestling see Biswas, 1960, JBNHS 57 (3): 542.

MEASUREMENTS

Nepal specimens give

	Wing	Bill	Tail
14 ♂♀	179-192	27-30 (from skull)	144-159 mm. (BB)

2 ♂♂ from Sikkim, wing 185, 188 mm. (Schäfer).

Thus it is evident that Baker's measurements loc. cit. (♂♀ Wing 208-226; bill (from feathers) c. 20-22; tail 151-176 mm.) do not relate to Himalayan birds.

Weight 1 ♂ 105; 1 ♀ 72 gm. (GD).

COLOURS OF BARE PARTS. Iris reddish brown or orange-red; eyerim yellow. Bill dark horny green, yellowish at gape. Legs and feet wax yellow to bright yellow. (For details see Biswas, loc. cit.)

580a. **Horsfield's Cuckoo.** *Cuculus saturatus horsfieldi* Moore
See Appendix

581. **Small Cuckoo.** *Cuculus poliocephalus poliocephalus* Latham

Cuculus poliocephalus Latham, 1790, Index Orn. 1: 214 (India)

Cuculus poliocephalus assamicus Koelz, 1952, Jour. Zool. Soc. India 4: 45
(Kohima, Naga Hills)

Baker, FBI No. 1455, Vol. 4: 142

Plate 51, fig. 9

LOCAL NAMES. *Dang-hlem* (Lepcha); *Pichu gipzu* (Bhutea); *Deo pia pihu* (Chachar).
SIZE. Myna +, with a longer tail. Length c. 26 cm. (10 in.).

FIELD CHARACTERS. Smaller than 579 but otherwise very similar: slaty grey above, black-barred white below, the underparts suffused with buff. Sexes more or less alike, but ♀ has also a hepatic phase. Most satisfactorily recognized by its distinctive husky chattering call, *That's your choky pepper* (accent on *choky*).

STATUS, DISTRIBUTION and HABITAT. Locally common and breeding in summer (April/May to July/August) in the Himalayas between c. 1500 and 3200 m. alt. (possibly to c. 4000 m.) from the Afghan frontier, Gilgit and Kashmir eastward, through Nepal, Sikkim, Bhutan, and NEFA. Also in Assam hills south of the Brahmaputra, Nagaland, and Manipur (?). Migrates in winter to lower elevations and the northern plains, wandering widely in the Peninsula south to Kerala (Cannanore). Recorded thus from Madhya Pradesh (Nagpur), Gujarat (Surat Dangs), Maharashtra (Dhulia, Ahmadnagar, Khandala), Mysore (Coorg, Belgaum), Tamil Nadu (Nilgiris),

CUCKOOS

215

variably coloured, white to terracotta red, usually matching the eggs of the normal local hosts. The egg is remarkably large for the size of the layer, and in the white phase almost indistinguishable from that of *C. saturatus*, a bird at least one-third larger. Average size of 30 eggs 21.0×14.2 mm. (Baker).

MUSEUM DIAGNOSIS. Smaller than *C. saturatus* and with edge of wing ashy. For description of immature plumages see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂♀	142-162	24-25 (from skull)	17-19	126-137 mm. (Various)

Baker's lower limits for wing (152 mm.) and tail (132 mm.) are misleading.

Weight 2 ♂♂ (Nepal, May), 48, 54 gm. — GD; 6 oo? (Pt Calimere, October) 32-44 gm. — SA.

COLOURS OF BARE PARTS. Iris brown; eyerim yellow. Bill blackish horny; base of both mandibles, commissure and gape yellow. Legs and feet wax yellow.

Genus CACOMANTIS S. Müller

Cacomantis S. Müller, 1843, Verh. Nat. Gesch. Ned. Land-en Volkenk., pt. 6: 177, note. Type, by subsequent designation, *Cuculus florus* Gmelin = *Cuculus merulinus* Scopoli

Penthorcyx Cabanis & Heine, 1863 (1862-63), Mus. Hein., Th. 4 (1): 16

Type, by monotypy, *Cuculus sonneratii* Latham

Contains small-sized cuckoos distinguished from *Cuculus* by shorter, more rounded wings with the primaries exceeding the secondaries by only about one-third length of wing. Tail as long as or longer than wing and well graduated.

Key to the Species

Page

- A Bill stout and not compressed; tail-feathers narrower posteriorly... *C. sonneratii* 215
B Bill compressed; tail-feathers of uniform width
1 Upperparts dark ashy; abdomen white or grey... *C. passerinus* 218
2 Upperparts ashy grey and brown; abdomen rufous... *C. merulinus* 220

CACOMANTIS SONNERATII (Latham)

Key to the Subspecies

- Upper plumage brighter and more rufous... *C. s. sonneratii*
Upper plumage darker and more brown... *C. s. tritii*

582. **Indian Baybanded Cuckoo.** *Cacomantis sonneratii sonneratii* (Latham)

Cuculus sonneratii Latham, 1790, Index Orn. 1: 215 (India)

Baker, FBI No. 1464, Vol. 4: 157

Plate 51, fig. 6

LOCAL NAMES. *Bata kati pitta* (Telugu); *Chakkiyil* (Malayalam); *Pānādi lāl kiyel* (Gujarati).

214

CUCULIFORMES

Cuculus poliocephalus poliocephalus

Breeding range

Winter

Andhra Pradesh (Nellore, Seshachalam Hills), and Andaman Is. Scarce visitor to Ceylon. Doubtless more generally dispersed but unrecorded owing to difficulty in identification when silent (in non-breeding season). Affects well-wooded country.

Extralimital. Breeds also in W. and C. China, Manchuria, and Japan from Hondo to Kiusiu. Recorded as migrant or straggler from E. China, the Bonin Is., Formosa (Taiwan), Ryukyu Is., S. Vietnam, etc. (Peters). Apparently scarce and local in the higher hills of Burma (Smythies).

MIGRATION. No ring recoveries. Passes through Pt Calimere ($10^{\circ}18' N.$, $79^{\circ}51' E.$) in numbers during October, presumably en route to Ceylon.

GENERAL HABITS and FOOD. Not significantly different from other members of the genus, qq.v. Very noisy in the breeding season, calling as much during the day, especially in cloudy weather, as at night; from a perch as well as on the wing.

VOICE and CALLS. A curious unmusical rattling, or chattering, cry of 5 or 6 notes, the first half going up in scale, the second coming down; well rendered as *That's your choky pepper... choky pepper* (accent on first *choky*). Uttered several times in quick succession, each repetition somewhat lower than the preceding. Timbre rather bulbul-like, but harsh and husky; pattern of call vaguely reminiscent of the *brain-feet* shrieks of *Cuculus varius* (573).

BREEDING. Brood-parasitic chiefly on small ground-nesting passerines of the family Muscicapidae, e.g. leaf warblers (*Phylloscopus*), wren-babblers (*Phoenicoglaea*) and shortwings (*Brachypteryx*). Season, May, June, July synchronizing with that of the hosts at various altitudes. Eggs, short, broad, elliptical;

216

CUCULIFORMES

SIZE. Myna +; slenderer. Length c. 24 cm. ($9\frac{1}{2}$ in.).

FIELD CHARACTERS. A small slim cuckoo: above, bright rufous or bay colour, conspicuously crossbarred with brown; below, including sides of head and neck, whitish with fine wavy brown cross-bars. Tail largely rufous, tipped with white and subtipped with black. Sexes alike. Easily confused with hepatic phase of female Plaintive Cuckoo (584, 585); see Museum Diagnosis.

x c. 1

Young (immature) similar to adult but with the rufous bars on the upperparts more pronounced, and the brown bars on the upperparts as well as the rufous on tail more extensive.

STATUS, DISTRIBUTION and HABITAT. Status unclear due to the bird being silent during non-breeding season when easily overlooked. Believed to be resident and nomadic as well as seasonal local migrant. Widely scattered in the monsoon season practically throughout India, sparse in the north, fairly common in the Deccan and southern India (excepting the areas of heaviest rainfall). Recorded from the lower Himalayas (up to c. 2400 m. alt.), foothills and plains, from Kumaon through Nepal, Sikkim and Bhutan to Assam (common in hills south of Brahmaputra R.), Gujarat, Madhya Pradesh, Orissa, W. Bengal. Commoner in southern Maharashtra, Andhra, Tamil Nadu, Mysore, Kerala, East Pakistan. Affects deciduous and evergreen lightly wooded country around cultivation, as well as fairly heavy forest.

Extralimital. Burma south to Tenasserim, Thailand, Vietnam.

GENERAL HABITS. Arboreal, usually keeping singly to bare tree-tops especially when calling, flying about from one to another. Sometimes springs up in the air to take a flying insect.

FOOD. Mainly caterpillars and bugs (Hemiptera). The red Silkcotton Bug (*Dysdercus singulatus*) is a favourite item with both this and the Plaintive Cuckoo.

VOICE and CALLS. A loud, rather pleasant 4-noted whistle *tee-ti-tee-ti* uttered with cuculine persistence and monotony from an exposed tree-top chiefly in the early morning and at dusk with tail depressed, rump-feathers fluffed out, and wings drooping at the sides; at all hours during overcast drizzly weather. The call is reminiscent of the *crossed-puzzle* calls of *Cuculus micropterus* (576) but is in a higher key and with a slightly different intonation. In addition has a sweet, clear whistling song of ventriloquial quality *tee-ti-tee-ti-tee-ti-tee-ti*?, rising in scale, ending interrogatively.

BREEDING. Brood-parasitic evidently on ioras (*Aegintha*), bulbuls (*Pyrenestes*), and small babblers (Timaliinae). Season, variable and prolonged (February to August), synchronizing locally with that of its hosts. Oviduct eggs broad oval in shape and variable in coloration. One common type is white or pinky white speckled with reddish- or purple-brown, usually resembling closely the eggs of the hosts. Average size c. 19.3×15.8 mm. (Baker).

CUCKOOS

217

MUSEUM DIAGNOSIS. Distinguished from the very similar hepatic female of Plaintive Cuckoo (584) by the tail-feathers being a little narrower towards their tips instead of uniformly broad throughout. Bill stouter and broader up to the tip, which is blunt seen from above.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	116-128	23-26	c. 17-18	112-118 mm. (SA)

COLOURS OF BARE PARTS. Iris brown. Bill horny black, olive-grey at base of lower mandible. Legs and feet greyish green; claws horny brown.

583. Ceylon Baybanded Cuckoo. *Cacomantis sonneratii waiti* (Baker)

Penthoceryx sonneratii waiti Baker, 1919, Bull. Brit. Orn. Cl. 39: 47 (Ceylon)
Baker, FBI No. 1466, Vol. 4: 159

LOCAL NAMES. *Kōhā* (Sinhala); *Kūyil* (Tamil).

SIZE. Myna +; slenderer. Length c. 24 cm. (9½ in.).

FIELD CHARACTERS. As of 582, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Race peculiar to Ceylon. Resident in all zones. Very local but moderately plentiful in many districts in the lowlands and lower hills to c. 750 m.; in winter (NE. monsoon season) visiting the Uva hills to over 1200 m. (Phillips). Affects borders of forest, chenas (shifting cultivation), and open jungle, preferably in the intermediate belt of country between the Wet and Dry zones (Henry).

GENERAL HABITS and FOOD. As in 582.

VOICE and CALLS. As in the Indian race. 'In the breeding season it utters a different note, a whistled *whew, whew, whu-u-u, whu-u-u, whu-u-u* — each stanza higher pitched than the last, the call ending abruptly as if the bird had reached the top of its compass — or run out of breath' (Henry). Most noisy in the mornings and evenings during the first quarter of the year, when presumably breeding.

BREEDING. 'Practically unknown. Victimizes the Orange Minivet (*Pericrocotus flammeus*) occasionally, if not regularly; and also the Little Minivet (*P. peregrinus ceylonensis*). Young observed in June and October' (Phillips).

MUSEUM DIAGNOSIS. Differs from the Indian bird in being much darker and browner above rather than rufous.

MEASUREMENTS. Baker gives Wing 121-126 mm.; bill (from feathers) 19-20 mm. Two specimens from Ceylon in the American Museum of Natural History, New York, measure:

	Wing	Bill (from feathers)	Tail
♂	129	20	111 mm.
♀	125	21	110 mm. (SDR)

COLOURS OF BARE PARTS. As in 582.

CUCKOOS

219

liability to be misidentified in the field or overlooked during the silent (non-breeding) period: resident in some parts of the country, nomadic or local migrant in others; from its calls perhaps most widely dispersed during the monsoons. Affects light open forest, gardens, groves of trees in village environs, shade trees in tea plantations, and the like.

GENERAL HABITS. General appearance and behaviour reminiscent of Dark Grey Cuckoo-Shrike. Keeps singly to foliage canopy of trees and bushes, mounting to their exposed tops for calling. Active and restless, constantly flying across swiftly from tree-top to tree-top over a wide area (its territory?) to call from different vantage points. Occasionally launches short flycatcher-like aerial sallies to capture flying bugs, or descends to the ground and hops a few steps to pick up caterpillars. When calling the tail is depressed, the rump arched (feathers fluffed out), and the wings drooped loosely at the sides.

FOOD. Hairy caterpillars (those of the moth *Nepita conferta* identified), bugs (*Dysdercus cingulatus* and others), and various soft-bodied insects.

VOICE and CALLS. Various. One commonly heard and quite diagnostic of the species is a rather plaintive single whistle *pileer* or *kiver* frequently repeated at short intervals. Another call is clearly of the Indian Cuckoo's *crossword-puzzle* pattern but in a higher key: *weeli-teeti* or *peter-peter*. The song proper is a clear lilting whistle of several notes ending interrogatively: *pee-pipee-pee*, *pipee-pee?* or its variant *pee-pipee-peepee*, *pipee-peepee?* ascending in scale and slightly higher pitched with each repetition. The calling bird turns its head this way and that, producing a marked ventriloquial effect. Most noisy in the mornings and evenings in the breeding season, but at all times of the day in cloudy, drizzly weather. Calls also during nights, whether dark or moonlit.

BREEDING. Brood-parasitic on warblers (Sylviinae) principally of the genera *Prinia*, *Cisticola* and *Orthotomus*. All these build more or less closed nests with narrow entrance-holes in which it is difficult to conceive the cuckoo introducing its egg in any way other than with the bill. The actual process needs determining. *Season* overall June to September, synchronizing locally with that of its hosts. *Eggs* long narrow ovals, appreciably smaller at one end. Coloration variable, usually matching those of the hosts. Average size of eggs 19.9 × 14.0 mm. (Baker). A remarkable case of adaptive selection has been revealed by Prof. R. K. Burnett in Andhra. He found that in Hyderabad city the Plaintive Cuckoo habitually laid in the nests of the locally abundant Ashy Wren-Warbler (*Prinia socialis*) which lays a uniform brick-red egg, whereas a few miles out in the surrounding country the principal host is the Tailor Bird (*Orthotomus sutorius*) whose eggs are reddish or bluish white spotted with brownish red. The eggs of the cuckoo in the respective areas 'mimic' those of the host in a convincing way. This would imply the evolution of remarkable plasticity in egg production, the urban population of the cuckoo being so strictly adapted as to lay an egg different from that of the population in the surrounding countryside. Whether the hatchling cuckoo evicts its rightful nestmates, as observed in the genus *Cacomantis* elsewhere, not known.

An extraordinary instance, fairly reliably reported from Poona (30 August 1944), of a chick of this cuckoo in the nest of a Purple Sunbird

218

CUCULIFORMES

584. Indian Plaintive Cuckoo. *Cacomantis passerinus* (Vahl)¹

Cuculus passerinus Vahl, 1797, Skriv. Naturhist.-Selsk., Kjobenhavn, 4(1): 57 (Tranquebar)

Baker, FBI No. 1462, Vol. 4: 154

Plate 41, fig. 7

LOCAL NAMES. *Pousya* (Marathi); *Chinna katte pitta* (Telugu); *Kōhā* (Sinhala); *Kūyil* (Tamil); *Cherūkūyil* (Malayalam); *Nāni rākhodi kōyāl* (Gujarati).

SIZE. Myna ±; slenderer. Length c. 23 cm. (9 in.).

FIELD CHARACTERS. A small slim cuckoo: *above*, dark grey and brown; *below*, chin, throat and breast grey, paling on abdomen and to whitish on vent. Tail blackish with a white tip and with the outer rectrices obliquely barred white. Occasional examples dark ashy throughout, and these easily confused with Dark Grey Cuckoo-Shrike (*Coracina melaschistos*, No. 1077).

A white patch on underside of wings (at base of primaries) conspicuous in flight. Sexes alike, but female dimorphic; in the hepatic (red) phase easily confused with Baybanded Cuckoo (582): bright chestnut-bay above and on throat, crossbarred with black on back, and with finely black-barred white underparts.

Young (immature) superficially similar to hepatic female: *above*, bright chestnut barred with black; *below*, chin, throat and breast suffused with chestnut with a few black bars; rest of underparts white finely and wavily barred with blackish. Tail-feathers marked longitudinally with black along the shafts. Some females moult from this dress direct into adult hepatic plumage.

STATUS, DISTRIBUTION and HABITAT. Throughout the well-wooded parts of the subcontinent including Nepal, Sikkim and Bhutan; up to c. 2700 m. altitude in the Himalayas; to c. 1800 in the Nilgiris and peninsular hills. Largely absent in W. Pakistan, western Rajasthan, northern Gujarat, and Kutch; not recorded from the Andaman and Nicobar Is. Occurs also in E. Pakistan, Ceylon ('winter visitor'), and Maldives Is. As in Baybanded Cuckoo (582), status evidently variable, but unclear chiefly because of

¹ Biswas (*Ibis* 93: 596, 1951) has shown that both *passerinus* and *merulinus* occur side by side in the breeding season without any intergrades. Therefore treated here as full species.

¹ Biswas (*Ibis* 93: 596, 1951) has shown that both *passerinus* and *merulinus* occur side by side in the breeding season without any intergrades. Therefore treated here as full species.

220

CUCULIFORMES

(*Nectarinia asiatica*) being fed in turns by the fosterers and by Tailor Birds (*Orthotomus sutorius*)! (M. F. Suter, JBNHS 45: 235).

MUSEUM DIAGNOSIS. For details of plumages see Whistler, H., 1944, *Spolia Zoolonica* 23 (3 & 4): 213-14.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	113-120	22-23	c. 17-19	105-115 mm. (SA, BB, HW)

COLOURS OF BARE PARTS. Iris brown. Bill horny brown, paler at chin and basal portion of lower mandible; mouth bright orange-brick colour. Legs and feet brownish yellow; claws horny brown.

585. Rufousbellied or Burmese Plaintive Cuckoo. *Cacomantis merulinus* Heine

Cacomantis querulus Heine, 1863, Jour. f. Orn. 11: 352, New name for *Polyphasia tenuirostris* Jerdon, not *Cuculus tenuirostris* Gray, 1834, which = *Cacomantis passerinus* (Vahl) (Lower Bengal, Assam, Sylhet, Burma, and China)

Baker, FBI No. 1463, Vol. 4: 156

Plate 51, fig. 5

LOCAL NAME. *Chhōta bhāru* (Bengal).

SIZE. Same as 584; length c. 23 cm. (9 in.).

FIELD CHARACTERS. A small, slim, ashy grey and brown cuckoo with white-tipped and barred blackish tail. Very similar to 584 (q.v.) but with the underparts, from breast down, rufous-buff to rusty red instead of white.

Female dimorphic, with a hepatic phase as in the Indian race.

Young (immature). Confusable with Baybanded Cuckoo on a superficial view. *Above*, barred brown and dull chestnut, including wings and tail. *Below*, chin, throat and foreneck chestnut, streaked with blackish; rest of underparts white, variably suffused with rufous and narrowly barred with dark brown.

STATUS, DISTRIBUTION and HABITAT. Status uncertain: locally resident, nomadic and migratory. Assam, Manipur, East Pakistan, West Bengal, the lower Himalayas to c. 2000 m. (also duars and terai) in NEFA and westward through Bhutan, Sikkim and Nepal. Has been taken in winter in eastern peninsular India west to c. 81°E. (Raipur, Madhya Pradesh) and south to c. 15°N. (Cumbum, Andhra Pradesh).

Affects well-wooded country — gardens, groves, shade trees in tea plantations, light open forest, and scrub jungle.

Extralimital. Eastward through Yunnan to Fukien, south through Burma, Thailand and the Indochinese countries to the northern Malay States; Hainan (Peters).

¹ This may be a juvenal *passerinus* fide Biswas (JBNHS 37: 520).

CUCKOOS

221

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 584.

BREEDING. Brood-parasitic on warblers—in the Assam hills chiefly on *Prinia* (*criniger*, *atrogularis*, *hodgsonii*), *Cisticola cuspis*, and *Orthotomus sutorius*. Season, April to August. Eggs varying in colour from pure white to pale blue, spotted and blotched with reddish brown, generally matching those of the hosts, only larger. Average size of 30 eggs taken at random 19.8 × 13.8 mm. (Baker).

MUSEUM DIAGNOSIS

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	109-119	15-17	17-18	112-125 mm. (Baker)

COLOURS OF BARE PARTS. As in 584.

Genus CHALCITES Lesson

Chalcites Lesson, 1830, *Traité d'Orn.*, livr. 2: 152. Type, by tautonymy, *Cuculus chalcites* Illiger, i.e. Lichtenstein, 1818 (Temminck, 1821, Pl. col., livr. 17, pl. 102, f. 2) = *Cuculus plagiator* Latham.

Small cuckoos of brilliant metallic plumage. Sexually dimorphic. Tail short and slightly rounded; wings long and pointed, the primaries exceeding the secondaries by more than one-third the length of the closed wing. Tarsus feathered almost throughout.

The genus extends through the Malay Peninsula and Indochinese countries to New Guinea; represented by two species in our limits.

Key to the Species

	Page
Upperparts glossy violet..... <i>C. xanthorhynchus</i> (♂)	223
Upperparts brilliant green..... <i>C. maculatus</i> (♂)	221
Upperparts light coppery green..... <i>C. xanthorhynchus</i> (♀)	223
Upperparts green, crown rufous..... <i>C. maculatus</i> (♀)	221

586. Emerald Cuckoo. *Chalcites maculatus* (Gmelin)

Trogon maculatus Gmelin, 1788, *Syst. Nat.* 1 (1): 404 (Ceylon)

Baker, FBI No. 1468, Vol. 4: 162

Plate 51, fig. 4

LOCAL NAMES. *Ang pha* (Lepcha); *Dao pu pip* (Cachar).

SIZE. Sparrow +; length c. 18 cm. (7 in.).

FIELD CHARACTERS. A diminutive resplendent-plumaged cuckoo.

Male (adult). Above, head, neck, and upperparts brilliant glossy green with golden bronze reflections. A white patch at base of primaries conspicuous in flight. Rectrices tipped white, the outermost pair with three irregular white bars. Below, chin, throat, and upper breast glossy green like back; rest of underparts white, barred with metallic bronze-green. Under tail-coverts metallic green, barred with white.

Female. Above, glistening emerald green with golden rufous crown and nape, these parts reminiscent of Little Green Bee-eater (*Merops orientalis*):

CUCKOOS

223

COLOURS OF BARE PARTS. Iris reddish brown to crimson; eyelids crimson. Bill bright orange-yellow tipped with black. Legs and feet dark brownish green.

587. Violet Cuckoo. *Chalcites xanthorhynchus xanthorhynchus* (Horsfield)

Cuculus xanthorhynchus Horsfield, 1821, *Trans. Linn. Soc. London* 13 (1): 179 (Java)

Baker, FBI No. 1467, Vol. 4: 160

Plate 51, fig. 7

LOCAL NAME. *Daopin-pip* (Cachar).

SIZE. Sparrow +; length c. 17 cm. (6½ in.).

FIELD CHARACTERS. A diminutive resplendent-plumaged cuckoo.

Male (adult). Above, head, neck and upperparts glistening metallic violet. Tail blackish, all the feathers tipped white, the outermost pair barred with same. Below, chin, throat, foreneck, and upper breast glistening violet; rest of underparts, including wing-lining, banded with broad white and violet (or green) bands.

Female. Above greenish bronze with a coppery tinge, and sometimes a little white on forehead; tips of primaries and rectrices greener. Tail banded green and chestnut and tipped white on all except the central pair of feathers. Below, including sides of head and neck, alternately banded with white and bronze-green, the bands narrowest on chin and throat, broadest on vent.

Young (immature). Above, barred rufous and brown. Below white, barred with brown.

Young males moult direct from the barred rufous stage into that of the adult and are never like the female (Baker).

Fledgeling. Like immature but with the entire head and neck (all round) streaked with black instead of banded.

STATUS, DISTRIBUTION AND HABITAT. Status uncertain; possibly various—resident, nomadic, and local migrant like 586 and other cuckoos. Assam, NEFA (?), Nagaland, Manipur, Tripura, East Pakistan (and possibly adjoining eastern W. Bengal); plains and up to c. 1500 m. alt. in the hills. Has been taken in the Andaman Is. in March, May, July and August; once at Perambur near Madras (season?—Whistler, JBNHS 37: 521). 'Winter status in India quite unknown' (Desfayes, M., 1974, JBNHS 71: 146). Affects secondary evergreen forest, keeping to clumps of trees, orchards, etc. and difficult to observe or detect unless calling.

EXTRALIMITAL. SW. Yunnan and central Vietnam, south to Malay Peninsula, Thailand, and S. Vietnam. Sumatra; Lingga Archipelago; Java; Borneo.

GENERAL HABITS AND FOOD. Very little known; presumably as of the Emerald Cuckoo.

VOICE AND CALLS. Not recorded in India. 'A shrill high-pitched trilling call resembling that of the nuthatch and barred woodpeckers' (D. M. Batchelor, 1963, *Sarawak Museum Journal* 21-2 N.S.: 278).

BREEDING. Brood-parasitic putatively on yellowbacked sunbirds (*Aethopyga*) and spiderhunters (*Arachnothera*) in the main. But since the supposed eggs taken in these nests are exactly like those of the Emerald Cuckoo and no oviduct eggs of this species are available for confirmation, the evidence remains only circumstantial. Average size of 7 of these supposed eggs 17.2 × 12.5 mm. (Baker).

222

CUCULIFORMES

tail barred chestnut and black, tipped with white. Below, white, tinged with rufous on throat and flanks and barred with bronze-brown, narrowest on throat, broader and wider apart on abdomen.

Young (fledgling ex nest). Above, barred rufous and brown, the marks on head elongate instead of across. Below, chin, throat and foreneck dull rufous streaked with black; rest of underparts barred alternately with dull white and brown.

STATUS, DISTRIBUTION AND HABITAT. Status uncertain. Possibly resident but subject to nomadism and local migration like other cuckoos. Occurs in the Himalayas (terai, bhabar, duars and foothills) up to c. 1000 m.—rarely to 1500 m. alt.—from Garhwal through Kumaon, Nepal, Sikkim, N. Bengal, Bhutan, and NEFA. Also Assam, Manipur, and East Pakistan. Once recorded from Ceylon, the type, possibly a stray. A straggler obtained at Adyar, a few miles south of Madras on 6 March 1878 (W. F. Digue, SF 9: 298); a specimen from Palni Hills in BNHS collection. Andaman and Nicobar Is. Affects evergreen jungle, chiefly secondary growth.

EXTRALIMITAL. Breeds in SE. Tibet and Szechuan to Hupeh, south to Burma, Yunnan and central Vietnam. Has occurred in winter or as a wanderer in Hainan, S. Vietnam, Malay Peninsula and Sumatra (Peters).

GENERAL HABITS. Keeps singly or in small parties of 4 to 6 to the higher branches in the foliage canopy of forest trees, and is difficult to observe except when flying across from tree to tree. Is unusually active for a cuckoo, constantly flitting from one bough to another or making aerial sorties after winged insects. In the breeding season is very vociferous, calling at intervals throughout the day and often far into the night, or all through if moonlit. Has a characteristic crouching stance when perched on a branch, along rather than across it, the tips of the closed wings projecting beyond the tail. Flight swift, reminiscent of a lorikeet.

FOOD. Ants, caterpillars, bugs (Hemiptera), and other soft-bodied insects, often taken on the wing.

VOICE AND CALLS. 'A very fine clear loud whistling call of 3 notes rapidly uttered' (Hume). 'A constantly uttered trill not unlike that of the lorikeet' (Bets). 'A quick high-pitched rattle of 5 or 6 notes descending slightly in pitch' (Smythies). 'A sweet twittering' (Stevens). 'A shrill but not unmusical succession of three notes in an ascending scale' (Baker).

BREEDING. Brood-parasitic chiefly on yellowbacked sunbirds (*Aethopyga* spp.), and spiderhunters (*Arachnothera* spp.). Season, 'middle April to end July' (Baker). Eggs, broad obtuse ovals usually white in ground colour, blotched and smudged with light brown or reddish brown, being passable replicas of those of the hosts, but larger. Average size of 17 eggs 16.9 × 12.3 mm. (Baker). Though not yet observed in the hatchlings of either this species or *C. xanthorhynchus*, other members of the genus (extralimital) are known to evict their rightful nest-mates from the nest.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail

MUSEUM DIAGNOSIS. See Key.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	95-105	16-17	14-15	64-72 mm. (Baker)

COLOURS OF BARE PARTS. Iris red; eyelids green with a red rim. Bill ♂ orange-yellow or bright yellow; ♀ dull yellow, dusky on culmen and base. Legs and feet brownish green; claws yellow.

Genus SURNICULUS Lesson

Surniculus Lesson, 1830, *Traité d'Orn.*, livr. 2: 151. Type, by subsequent designation, *Cuculus lugubris* Horsfield

Genus remarkable for its extraordinary superficial resemblance to the Black Drongo (*Dicrurus adsimilis*) in shape, proportions and coloration. Differs from all other cuckoos in the tail being long and forked, the central pair of rectrices falling short of the outermost pair by about one-third the length of the tail. Bill as in *Camomantis*.

SURNICULUS LUGUBRIS (Horsfield)

Smaller.....	<i>S. l. stewarti</i>

588. Indian Drongo-Cuckoo. *Surniculus lugubris dicruroides* (Hodgson)

Pseudornis dicruroides Hodgson, 1839, *Jour. Asiat. Soc. Bengal* 8: 136 and pl. (Mountains of Nepal)

Baker, FBI No. 1470, Vol. 4: 165

Plate 67, fig. 11

LOCAL NAMES. *Kario-tyem* (Lepcha); *Kakkālamparātti kūyil* (Malayalam).

SIZE. Same as of the Black Drongo. Myna ±; slimmer, with longer forked tail. Length c. 25 cm. (10 in.).

FIELD CHARACTERS. Overall glossy metallic black. General appearance, size, and forked tail deceptively like Black Drongo, but under tail-coverts and outermost tail-feathers near their base nearly always barred with white. Calls entirely diagnostic (see below). Sexes alike.

Young (immature) has the plumage unglossed, the feathers of the head, back and breast with many terminal white spots; wing-coverts tipped with white; more white on tail and under tail-coverts.

Fledgeling dull black speckled all over with white.

STATUS, DISTRIBUTION AND HABITAT. The lower Himalayas up to c. 2000 m. alt. and submontane tracts (terai, bhabar, and duars) from Punjab and Himachal Pradesh through Garhwal, Kumaon, Nepal, Sikkim, Bhutan, and NEFA. Also Assam, Nagaland, Manipur and East Pakistan. Occurs at one time or another, chiefly detected during the monsoons when vocal (June to October/November), practically throughout the better wooded parts of the Peninsula (plains and up to at least 1500 m. in the hills) south

CUCKOOS

225

to Tamil Nadu and southern Kerala. But status south of the Himalayas unclear and difficult to determine due to possible confusion with Black Drongo unless verified by specimens or by its diagnostic calls which are 'on the air' only during breeding season. Status probably varies from locality to locality between breeding, nomadism, and local migration. Affects open secondary forest, plantations, orchards, etc.; sometimes dense evergreen jungle.

Extralimital. Eastward across to southern China (north to southern Yunnan and central Fukien), southward to Tenasserim, Thailand, the Indochinese countries and Hainan I. Recorded from Sumatra apparently as a migrant (Peters).

GENERAL HABITS. Superficial appearance deceptively like Black Drongo but is comparatively sluggish and less alert. Entirely arboreal. Keeps singly to the foliage canopy of trees and shrubs, mounting to the exposed bare branches for calling. Where available, snags of the fronds of palms, e.g. palmyra (*Borassus*), form favourite singing posts. Normal perching stance upright, when the resemblance to Black Drongo is heightened; while calling assumes a more horizontal axis, rather 'humped up' and with the wings slightly drooped at the sides. Flight cuckoo-like and noticeably different from drongo's. Sometimes springs up in the air to capture a flying insect very like a Bronzed or Ashy drongo, or clings to a vertical tree-trunk to pick off a caterpillar. Apparently disperses widely during the monsoon, its distinctive calls announcing its arrival and presence in a locality. In the breeding season calls persistently in the mornings and evenings; at all hours of the day in overcast, drizzly weather. Often also throughout the night. Like other cuckoos, silent in non-breeding season, making its local status difficult to determine.

FOOD. Hairy and other caterpillars, soft-bodied insects, and occasionally fruit, e.g. banyan and peepul figs (*Ficus* spp.).

VOICE AND CALLS. 'Song', a run of 5 or 6 (sometimes up to 7 or 8) evenly spaced high-pitched musical whistling notes *pip-pip-pip-pip-pip* (exactly as if the bird was counting 1-2-3-4-5-6 or practising the musical scale), rising in pitch with each *pip* and breaking off abruptly to be reiterated afresh after a few seconds, with monotonous persistency. Another call, mostly heard late in the season, is like a shrill version of the beginning of the *brain fever* shrieks of the Hawk-Cuckoo and is 'accompanied by a lifting of both wings to touch above the back' (Mrs Wright, 1957, JBNHS 54: 653). The significance of this call is not understood.

BREEDING. Very imperfectly known. Brood-parasitic reportedly on drongos (*Dicrurus*), forktails (*Enicurus*), minivets (*Pericrocotus*), and Black-headed Babbler (*Rhopocichla atriceps*). Season presumably March to October (January to March in Kerala?) when most widely vocal and gonads of specimens in breeding condition. Eggs. Dependable data lacking. An oviduct egg was 'heavily spotted purplish around ends' (Biswas).

MUSEUM DIAGNOSIS. In the hand the exposed round nostril, shape of bill, and structure of foot (zygodactyle) immediately distinguishes it from the black drongo (*Dicrurus adsimilis*). In the latter the bill is shrike-like hook-tipped, and it has the characteristic perching foot with three toes in front and one behind. For distinguishing from the Ceylon race see Key.

590. Indian Koel. *Eudynamys scolopacea scolopacea* (Linnaeus)

Cuculus scolopaceus Linnaeus, 1758, Syst. Nat., ed. 10, 1: 111 (Malabar)
Baker, FBI No. 1475, Vol. 4: 172

r¹late 70, fig. 1

LOCAL NAMES. Koel (Hindi); Kōkil, Kōkila (Bengal, Marāthi); Nalla kōvēla ♂, Poda kōvēla ♀ (Telugu); Kūyil, Pūlikūyil, Kākkākūyil (Malayalam); Kōhā, Gomerā kōhā (Sinhala); Kūyil (Tamil); Karlu koel ♂, Dindin koel ♀ (Maldivé Is.).

SIZE. House Crow±; slimmer and with longer tail. Length c. 43 cm. (17 in.).

FIELD CHARACTERS. Male (adult) glistening metallic black all over, with yellowish green bill and crimson eyes. Distinctive shrieking crescendo calls: *kūoo, kūoo*, etc.

♂, x c. 1

Female. Above, dark brown, profusely white-spotted and barred. Tail-feathers and wing-quills barred with white. Below, white; spotted on chin, throat and foreneck, barred on rest of underparts with blackish.

Fledgeling (in nest). More or less like adult, sex for sex, but female far darker and more sooty above with blackish head, throat and breast; thus closer in the character of its plumage, especially upperparts, to male rather than to adult female as is the norm in birds. This adaptation is presumably of some survival value amidst the black nestlings of its normal fosterers, the House and Jungle crows. Bill black not green as in adult.

STATUS, DISTRIBUTION AND HABITAT. Resident, nomadic, and local

¹A figure derived by dividing the smaller (tail) measurement by the larger (wing) measurement.

CUCULIFORMES

MEASUREMENTS

	Wing	Bill (from skull)	Tail
♂ ♀	135-148	23-26	128-152 mm. (BB, SA, SDR)

Tarsus c. 19 mm. (Baker).

COLOURS OF BARE PARTS. Iris dark brown or reddish brown. Bill brownish black. Legs and feet bluish slaty or pinkish plumbeous; claws horny brown.

589. Ceylon Drongo-Cuckoo. *Surniculus lugubris stewarti* Baker

Surniculus lugubris stewarti Baker, 1919, Nov. Zool. 26: 293 (Ceylon)
Baker, FBI No. 1471, Vol. 4: 166

LOCAL NAMES. Kāūdā kōhā (Sinhala); Irattāi-rālan kūyil (Tamil).

SIZE. Same as 588; Black Drongo.

FIELD CHARACTERS. Deceptively drongo-like. See under 588, also for immature and fledgeling.

STATUS, DISTRIBUTION AND HABITAT. Race peculiar to Ceylon. 'Widely but locally distributed and resident, in small numbers, in forest areas throughout the lowlands; visits the hills to 4000 ft. [c. 1200 m.] when not breeding' (Phillips). Frequents shade trees in tea plantations etc.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in the Indian bird, 588, q.v.

BREEDING. Little known. Brood-parasitic supposedly on Iora (*Argithina tiphia*) and Blackheaded Babbler (*Rhopocichla atriceps*); possibly also other species. Season probably from December to May.

MUSEUM DIAGNOSIS. Somewhat smaller in wing and bill but otherwise identical with the Indian *dicruroides* in colour and wing formula (*contra* Baker); doubtfully meriting separation. Baker gives for Ceylon birds Wing ♂ ♀ 123-131 (av. 126.5) mm.; tail 136-146 mm.

3 ♂♂ measured by HW and SDR have Wing 127-128; bill (from skull) 23 (1), (from feathers) 20-20.5 mm.; tail 136-146 mm. 1 ♀ Wing 130; bill (from feathers) 19; tarsus c. 16-18 mm.; tail 141 mm.

COLOURS OF BARE PARTS. As in 588.

Genus EUDYNAMYS Vigors & Horsfield

Eudynamys Vigors & Horsfield, 1826, Trans. Linn. Soc. London 15 (1): 303. Type, by subsequent designation, *Cuculus orientalis* Linnaeus

No crest. Bill stout, the culmen rounded and much curved. Wing and tail more or less equal in length, the latter moderately graduated and with broad rectrices. Tarsus stout, strongly scutellate in front, only feathered at extreme upper end. Sexes dimorphic.

Ranges throughout the Oriental Region to New Guinea and Australia. Only 1 species with 3-races occurs within our limits. Numerous other extralimital races extend the species through SE. Asia to Australia.

228

CUCULIFORMES

migrant throughout the subcontinent excepting Assam and East Pakistan (see under 591). Described as summer visitor in many localities in north and peninsular India, and as winter visitor in the south. However, its silence and retiring behaviour during the non-breeding period is apt to convey a misleading impression regarding its local status, and these dicta must be treated with reserve. Rare or absent in the more arid tracts of W. Pakistan, western Rajasthan and northern Gujarat, but spreading gradually in the wake of advancing colonization and its inseparable concomitant the House Crow. Common resident in Ceylon, and the Maldivé and Laccadive Is. (status?). Occurs locally up to c. 1000 m. in the peninsular hills, and to c. 1800 m. in the outer Himalayas from Punjab and Kashmir across to NEFA, including Nepal, Sikkim, and Bhutan. Occurrence and local abundance everywhere closely linked with its principal fosterers the House and Jungle crows (*Corvus splendens* and *C. macrorhynchos*). Affects lightly wooded country — gardens, mango orchards, and groves of trees in and around cultivation and towns and villages.

MIGRATION. See Appendix

GENERAL HABITS. Arboreal, the bird usually keeping to the seclusion of leafy trees and shrubs, thus apt to be easily overlooked. Normally silent and unobtrusive, seldom showing itself except while it dashes across, almost fugitively, from one tree to another in short hurried flight. However, with the approach of the hot weather and its breeding season, coincident with that of its principal hosts the House and Jungle crows, waxes aggravatingly vociferous, shrieking its shrill crescendo calls chiefly in the morning and late afternoon, but often all through the day and far into the night. It is then one of the first bird voices of the dawn, commonly heard while still quite dark, and long before its early-rising dupes, the crows, are up and astir. Flight swift and direct with rapid wing-beats — rather hawk-like.

FOOD. Largely fruits and berries, some commonly recorded species being banyan and peepul figs (*Ficus bengalensis* and *F. religiosa*), ber (*Zizyphus*), mulberry (*Morus*), sandalwood (*Santalum album*), *Cinnamomum camphora*, *Cephalandra indica*, and nuts of the Fishtail palm (*Caryota urens*). Poisonous fruits of *Thevetia nerifolia* also freely eaten. Other items: hairy caterpillars, bugs (Hemiptera) and various insects, terrestrial snails, eggs of small birds, e.g. oriole and bulbul, filched from nests, and flower nectar, e.g. of *Erythrina indica*.

VOICE AND CALLS. The calls commonly heard are:

1. A loud, continuous, rollicking *Urūk-keo-keo-keo-keo-keo-keo* (6 or 7 times repeated) without change of pitch but varying in insistence and shrillness, uttered by the male at earliest dawn as the first call of the day evidently to announce himself or as a challenge to other cocks in the neighbourhood. These soon answered similarly by another male (or males) in the distance and repeated by each at intervals of a minute or so, sometimes assuming the form of an uneven duet. Later in the morning the calls usually settle down to the characteristic 'song'.

2. Song, a loud shrill shrieking whistle *kūoo, kūoo*, etc. rising in scale with each repetition to frantic pitch at the 7th or 8th, then breaking off abruptly. The bird soon commences it all over again, and so on and on *ad nauseam*.

CUCKOOS

229

3. Normal call of female a shrill, quick-repeated *kik-kik-kik-kik* etc. as she dashes from tree to tree in courtship chase by male, or hops amongst the branches ostensibly to escape his ardour.

In addition various croaks, gurgles, and chuckles uttered by both sexes under different provocations. Flying fledgeling emits a loud harsh *kaaa* — a passable imitation of young crow.

BREEDING. Brood-parasitic almost exclusively on House and Jungle crows (*Corvus splendens* and *C. macrorhynchos*) combining strategem, cunning, and opportunism to lay in their nests. (For details of the process, and breeding biology, see D. Dewar, 1907, JBNHS 17: 765 et seq.; B. S. Lamba, 1963, JBNHS 60: 130-3; 1966, *ibid.* 63: 750-1.) Exceptionally, eggs have been found in nests of *Oriolus o. kundoo* (D'Abreu, JBNHS 31: 1032) and *Acridotheres tristis* (Inglis, *ibid.* 18: 682). Season everywhere synchronous with that of its hosts, overall March to August, chiefly May to July but varying locally. Eggs very similar in appearance to crows' only smaller — greenish grey in ground colour, profusely blotched and speckled with reddish brown. Average size of 100 eggs 31.0 × 23.6 mm. (Baker). As many as 11 eggs once found in a single crow's nest, evidently the product of several females. Eggs of host and parasite frequently found together in the same nest, and also young of both. Unlike cuckoo (*C. canorus*) koel hatchling does not eject contents of fosterer's nest, but in this case the shorter incubation period (13-14 days v. 16-17 in House Crow and 18-20 in Jungle Crow) gives it sufficient advantage to monopolize the food brought by the fosterers and gradually to starve out its lawful nest companions. Thus koel and crow fledgelings from the same nest seldom seen together though not unknown. Feeding of koel fledgeling outside the nest by adult female koel has been frequently observed.

MUSEUM DIAGNOSIS. See Key.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	182-205	29-34	32-35	186-205 mm.
♀♀	179-203	30-34	31-35	171-189 mm.

(SA, HW, SDR, BB)

Weight 10 ♂♀ 136-190 (av. 167) gm. — BNHS.

COLOURS OF BARE PARTS. Iris crimson. Bill apple green or yellowish green, blackish at base and dusky round nostrils. Legs and feet plumbeous; claws horny; pads of sole whitish.

Milias tristis Lesson, 1830, *Traité d'Orn.*, livr. 2: 132 (Sumatra, *errata* = Bengal)
Baker, FBI No. 1479, Vol. 4: 178
Plate 52, fig. 4

LOCAL NAMES. *Bon kakil* (Bengal); *Bemura* (Assam); *Sanku* (Lepcha).

SIZE. Pigeon ± with tail c. 38 cm. long. Overall length c. 51 cm. (23 in.).

FIELD CHARACTERS. A long-tailed cuckoo with naked crimson orbital patch and yellowish green bill. Sexes alike. Long graduated rectrices with broad white tips very conspicuous in flight, especially when tail spread before alighting.

Adult. Above, forehead grey with shiny bristly black shafts to the feathers. Upperparts dark ashy grey with deep green gloss. Tail green-glossed black, long, broad, steeply graduated, the rectrices cross-rayed darker and broadly tipped with white. Below, chin, throat and sides of head yellowish ashy grey, darkening to blackish on lower abdomen and vent. Feathers of chin, throat, and breast with black bristly shafts.

Young (immature) undescribed.

Fledgeling (1 ♂ taken in central Nepal, June 1). Coloration similar to that of adult birds; the tail proportionately very small (Biswas, 1960).

STATUS, DISTRIBUTION AND HABITAT. The outer Himalayas from the terai, bhabar and duars up to c. 700 m. altitude (commonly) and to c. 1800 m., from Garhwal eastward through Kumaon, Nepal, Sikkim and Bhutan to NEFA where it intergrades with *saliens* (594) in the Mishmi Hills. Also Assam (Lakhimpur, Sibsagar, Cachar Hill dists.), Nagaland, Manipur, Tripura, W. Bengal (duars and Sunderbans) and E. Pakistan (Dacca and Chittagong dists.). South through Chota Nagpur (Manbhum and Hazaribagh dists.) and eastern Madhya Pradesh (Bastar dist.) to c. 18°50'N. Affects dense thickets and shrubbery in evergreen jungle.

GENERAL HABITS. Rather sluggish, skulking, and silent. Keeps to the seclusion of impenetrable thickets, creeping its way through the dense cover with remarkable celerity, and is seldom seen except in short flight from one thicket to another. Usually works low down in the bushy tangles, sometimes mounting into thickly foliated saplings and forest trees, diving into the undergrowth on alarm. When shooting down a hillside thus, looks very like tree pie in the distance. Hops its way up gracefully, almost gliding from

230

CUCULIFORMES

STATUS, DISTRIBUTION AND HABITAT. Assam, southern NEFA, Nagaland, Manipur, Mizo (?), Tripura, East Pakistan.

Extralimital. Burma, Thailand, Malaysia, Indonesia.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 590.

BREEDING. Nothing recorded as specifically different from the Indian bird. **MUSEUM DIAGNOSIS.** Slightly larger than the nominate race and with a larger bill. Male often indistinguishable from the Indian bird; female much more rufescent above and below.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail

Eudynamis scolopacea dolosa Ripley, 1946, Auk 63: 241 (Barren Island, Andamans)
Not in Baker, FBI

LOCAL NAME. Koel (Hindi).

SIZE. House Crow ±; slimmer and with a longer tail. Length c. 43 cm. (17 in.).

FIELD CHARACTERS. As for the Indian Koel (590), q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Andaman and Nicobar Islands.

Formerly recorded (Osmaston, 1905, 1906, JBNHS 16: 621; 17: 487) only as a common winter visitor September-April, as it apparently still is to Narcondam and the Nicobars; but present status needs checking.

Frequents jungle and trees around the settlements.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in the Indian bird (590), q.v.

BREEDING. Unrecorded.

MUSEUM DIAGNOSIS. Larger than nominate *scolopacea*. Upperparts of female more blackish, and conspicuously spotted with rufous-buff. Rufous wash extends over all the white parts including chin, lower abdomen, and under tail-coverts. Wing/tail index smaller than in *E. s. malayana*. See Key.

MEASUREMENTS

	Wing	Tail
♂♂	203-235	189-221 mm.
♀♀	201-216	184-197 mm.

(SDR)

Bill (from feathers) ♂♀ 27-34 mm. (HA).

Genus RHOPODYTES Cabanis & Heine

Rhopodytes Cabanis & Heine, 1863 (1862-63), Mus. Hein., Th. 4(1): 61. Type, by subsequent designation, *R. diardi* = *Melias diardi* Lesson

Bill deep, compressed, pale green or apple-green in colour; nostril small, round or oval, and oblique. A large naked space round orbit, blue or crimson, separated from bill by a narrow band of feathers. No bristly eyelashes as in *Taccoua*, q.v.

232

CUCULIFORMES

branch to branch with occasional flicks of the long tail. Flight weak, laboured and ill sustained.

FOOD. Large caterpillars and insects, e.g. grasshoppers, mantids, and crickets; also lizards, and probably other small animals.

VOICE AND CALLS. A very peculiar low croaking *ko, ko, ko* uttered at intervals of a few seconds. 'A peculiar cat-like chuckle' when flushed in dense cover (Davison).

BREEDING. A non-parasitic cuckoo. Season, April to August, varying somewhat locally. Nest, very small for size of the bird; a rather flimsy cup like a dove's, of twigs and rootlets lined with green leaves; sometimes formed by a mere interlacing and twining of the surrounding green leaves and tendrils. Placed between c. 3 and 7 m. up, in tangled masses of creepers smothering a sapling or bamboo clump, in heavy jungle with no special effort at concealment. Eggs, 2 to 4, most commonly 3, chalky white varying in shape from elliptical to longish oval. Average size of fifty eggs 33.8 × 25.8 mm.; incubation by both sexes (Baker). Period undetermined.

MUSEUM DIAGNOSIS. Differs from the Burmese race *saliens* (594) chiefly in having a larger wing. See Key.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	165-176	36-37	40-43	375-385 mm.
♀♀	164-173	36-40	40-43	345-425 mm. (SA, BB, SDR)

Tail moult in the species centripetal (Biswas).

Weight 1 ♂ juv. 116; 1 ♀ juv. 114 gm. (GD).

NOTE. In 1949 SA collected a ♂ and ♀ in Bastar dist., M.P. which, apart from being the smallest so far examined (W. 157 and 146 mm. respectively) also represent the most southerly point in the distribution within our limits.

COLOURS OF BARE PARTS. Adult. Iris brown (rarely crimson); orbital skin deep crimson. Bill dark green with red on the base and around nostrils. Legs and feet greenish slaty; claws horny; sole pads white. Fledgeling. Iris brown; orbital skin dark brown. Bill: upper mandible slaty horn, lower mandible greenish horn. Legs and feet pale plumbeous; claws dark horny; sole pads white (BB).

594. Burmese Large Greenbilled Malkoha. *Rhopodytes tristis saliens* Mayr

Rhopodytes tristis saliens Mayr, 1938, Ibis: 306 (Chapa, Tonkin)
Not in Baker, FBI

LOCAL NAMES. Unrecorded.

SIZE. Pigeon ± with tail c. 38 cm. long. Overall length c. 51 cm. (23 in.).

FIELD CHARACTERS. As for 593, q.v. See Key to the Subspecies and Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Mishmi Hills, NEFA, where it intergrades with the nominate race (593). Birds from Nagaland approach this race, but less closely than the virtual intermediates of the Mishmis.

Extralimital. Bhamo and the Upper Chindwin dist. of Burma, SW. Yunnan and Tonkin [N. Vietnam], southward to the mountains of N. Siam, N. Laos and N. Annam [C. Vietnam] — Peters.

CUCKOOS

233

GENERAL HABITS, FOOD, VOICE and CALLS. Not different from 593.
BREEDING. Not recorded in our limits.
MUSEUM DIAGNOSIS. See Key. * Smaller than *tristis*. Wing 152-163 (av. 155.4); tail 364-394 (av. 377.9), once 347; underparts not very much washed with ochraceous; crown, back, and underparts rather dark; white on forehead and superciliary not extensive; gloss on wings and tail rather bluish; white tips on tail feathers narrow; . . . (Mayr, loc. cit.).
2 ♀♀ from the Mishmi Hills (intermediate) measure 'Wing 164-167; culmen 34-37; tail 330-372 mm. The wing measurement agrees with *tristis*, but the tail with *saliens*. The upperparts are darker than in *tristis*' (SDR).
COLOURS OF BARE PARTS. As in 593.

Zanclostomus viridirostris Jerdon, 1840, Madras Jour. Lit. Sci. 11: 223 (bottom of the Coonoor Pass)
Baker, FBI No. 1478, Vol. 4: 177 Plate 52, fig. 1

LOCAL NAMES. *Kappra*, *Pohiya* (Hindi); *Wāmanā kākī* (Telugu); *Kalahā kōhā*, *Pūnchi māl kōhā* (Sinhala); *Kūyil* (Tamil); *Pācha chūdān* (Malayalam).

SIZE. House Crow —; slimmer and with a longer tail. Overall length c. 39 cm. (15½ in.).

FIELD CHARACTERS. An untidy looking greenish ashy-grey cuckoo, suffused with rufous on the underparts. Bright green bill, naked blue patch round eye, and long, broad, graduated tail with conspicuous white tips to the feathers, are diagnostic pointers. Sexes alike.

Young (immature). Undescribed, but see Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident; locally common. Ceylon (low-country Wet and Dry zones), and peninsular India roughly north to lat. 20°N.; northernmost record on the western side Baroda (Gujarat, c. 22°20'N.), on the eastern Cuttack (Orissa, c. 22°25'N.). Affects deciduous and semi-evergreen scrub-and-bush terrain with euphorbia and lantana brakes, and open secondary jungle — plains and broken foothills country up to c. 1000 m. alt.

GENERAL HABITS. Keeps singly or in pairs to low bushes and thorn scrub, skulking its way through the thickets and clambering about actively among the branches. Seldom if ever descends to the ground, but habits and behaviour otherwise clearly reminiscent of the Crow-Pheasant. Is a poor flier, rarely seen on the wing except in short laboured flight from one thicket to another; normally preferring to creep away through the tangled shrubbery on alarm.

FOOD. Caterpillars and large insects such as grasshoppers and mantises. Also lizards and other small animals, and probably berries.

VOICE and CALLS. Very silent and seldom heard: a low croak, sounding like *kraa*.

BREEDING. Non-parasitic. Season ill defined; breeds practically all the year, perhaps more specially between March and May. Nest, an untidy saucer of thorny twigs, rather like a dove's, placed in a thorn bush or euphorbia brake or bamboo clump a metre or two above the ground. Eggs, almost

CUCKOOS

235

FIELD CHARACTERS. An obvious relation of the crow-pheasant and malkohas. A heavy-tailed earthy brown and rufous cuckoo with fine glistening black shaft-streaks to the head and breast feathers, and a stout bright

× c. 1

cherry-red and yellow bill. Broad white tips to the graduated cross-rayed blackish tail-feathers conspicuous in flight. Sexes alike.

Fledgeling. Feathers of back, scapulars, and wing-coverts edged with pale rufous; feathers of head dully centred blackish; of chin, throat, breast, flanks and upper abdomen boldly streaked with black (Baker).

STATUS, DISTRIBUTION and HABITAT. Resident. West Pakistan (Sind, Punjab) and NW. India — Himachal Pradesh, Garhwal, parts of southern Uttar Pradesh, western Madhya Pradesh, and ? eastern Maharashtra (Nagpur area); Rajasthan, Gujarat (including Kutch and Saurashtra) south to about Cambay, c. 22°20'N. lat. Precise limits undefinable as the populations intergrade over extensive areas.

Was practically unknown in Sind till the early thirties of the present century, but has established itself since, and is steadily expanding its range consequent on the opening up of desert areas by the perennial canal system of the Sukkur Barrage (N. H. Menesse, 1939, JBNHS 41: 172-3).

Affects deciduous tangled thorn and grass jungle, particularly in stony, broken ravine country, often semi-desert.

GENERAL HABITS. Largely terrestrial; usually keeps singly or in pairs, stalking along on the ground or threading its way through the thickets in search of food. Sometimes mounts into shrubs or saplings clambering amongst the twigs or hopping upward actively from branch to branch in the manner of a crow-pheasant. Flight weak and laboured: is loth to take wing unless deliberately beaten out of the undergrowth or almost trod upon in tall grass. Prefers to trust to its legs for escape when disturbed, sprinting swiftly over loose stones and rough ground with head ducked and tail horizontal, dodging deftly in and out of thickets, then looking singularly like a mongoose in the distance.

Courtship display consists of a ludicrous repeated bowing (or bobbing) by one bird of a pair (in one case verified as female) before the other, with its plumage fluffed out and tail cocked and expanded like a rounded fan, the white tips of the rectrices showing up as a conspicuous band. At other times both birds partake in these antics with equal enthusiasm, puffing out their plumage, fanning and erecting the tails, and repeatedly bowing low

234

CUCULIFORMES

invariably 2, exceptionally 3, chalky white, roundish. Average size of 6 eggs 29.4 × 24.8 mm. (Baker). Share of the sexes in nest building and incubation, and incubation period, undetermined.

MUSEUM DIAGNOSIS. Feathers of chin and throat bifurcate, a character absent in *tristis*, the bifurcated portion yellowish, giving a streaked appearance.

Ceylon birds have a larger extent of white on the outer web at the tips of the 2nd and 3rd tail-feathers (counting from outside) than those from the Peninsula; S. Kerala birds are closer to Ceylon in this respect. (For details see Whistler, 1934, JBNHS 37: 525.) Ceylon birds moreover have a somewhat heavier bill.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂♂	131-143	29-33	32-36	202-246 mm.
♀♀	129-140	28-34	32-34	218-240 mm.
		(from skull)		(SA, HW)

Weight 21 ♂ ♀ 52-82 (av. 67) gm. — BNHS.

COLOURS OF BARE PARTS. Iris, fine outer ring white, inner claret; crinkled warty circumorbital skin pale blue. Bill greyish green; mouth brownish black or slaty black. Legs and feet olive-slate; claws dusky.

Genus TACCOCUA Lesson

Taccocua Lesson, 1830, *Traité d'Orn.*, livr. 2: 143. Type, by monotypy, *Taccocua leschenaultii* Lesson

Bill shorter and deeper than in *Rhopodytes*; upper mandible distinctly festooned near base. Wings short and rounded. Tail long, broad, and graduated; upper tail-coverts more than half length of tail. Plumage of head, neck, upper back, and breast spinous; shafts of the forehead-feathers projecting. A row of coarse bristles (like eyelashes) nearly surrounding the eye except behind. Tarsus stout; claws short and curved.

A single species, peculiar to and widely distributed in India and Ceylon.

596. Western Sirkeer Cuckoo. *Taccocua leschenaultii sirkee* (J. E. Gray)

Centropus sirkee J. E. Gray, 1831, in Hardwicke's Ill. Ind. Zool. 1 (6), pl. 28 (No locality = Cawnpore)

Taccocua leschenaultii oventyni Koelz, 1954, *Contrib. Inst. Regional Exploration*, No. 1: 24 (Sasan, Junagadh, Saurashtra)
Baker, FBI No. 1487, Vol. 4: 187

LOCAL NAME. *Jāngli tōā* (Hindi).

SIZE. House Crow ± with longer broader tail; overall length c. 42-44 cm. (16½-17¼ in.).

CUCULIFORMES

236

to each other with beaks wide open, each bow commencing with the head thrust high into the air.

FOOD. Caterpillars, locusts, grasshoppers, termites, and other insects; fallen fruits and berries; lizards.

VOICE and CALLS. Normally silent. Occasionally a sharp *kek-kek-kek-kerek-kerek-kerek* or *kik-kik-kik* of the tone quality of the Roseringed Parakeet's shrieks; in a way reminiscent also of some of the Barred Jungle Owlet's calls.

BREEDING. Non-parasitic. Season, chiefly June to August. Nest, very similar to the malkohas', an untidy saucer of twigs lined with green leaves, roughly wedged into the fork of a 'cactus' (*Euphorbia*) or branching shrub up to about 6 metres from the ground, normally between two and three. Not deliberately concealed, but easily overlooked. Eggs, 2, rarely 3 (once 4, Currie, JBNHS 24: 604), chalky white, unmarked. Average size of 12 eggs 36.2 × 27.3 mm. (Baker). Both sexes incubate. Period of incubation undetermined.

MUSEUM DIAGNOSIS. See Key. * Upperparts much as in *leschenaultii* [q.v.]; lower parts paler and more rufescent and also more uniform, the foreneck and breast being more or less concolorous with the belly' (Whistler).

MEASUREMENTS

24 ♂♀ Wing (once 148) 153-168; bill (from skull) 30-34 mm. (HW).

COLOURS OF BARE PARTS. Iris brown. Bill magenta-crimson or cherry-red, yellow at tips of both mandibles and brown along commissure; mouth slaty black. Legs and feet slaty; claws horny brown.

597. Eastern Sirkeer Cuckoo. *Taccocua leschenaultii infusca* Blyth

Taccocua infusca Blyth, 1845, *Jour. Asiat. Soc. Bengal* 14 (1): 200 (Sub-Himalayan region; type from the terai region near Darjeeling)

Taccocua affinis Blyth, 1846, *Jour. Asiat. Soc. Bengal* 15: 19 (Rajmahal and Monghyr Hills)
Baker, FBI Nos. 1488, 1489, Vol. 4: 187, 188

LOCAL NAME. *Jāngli tōā* (Hindi).

SIZE. As 596, House Crow ± with longer, broader tail.

FIELD CHARACTERS. As of 596, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident. The sub-Himalayan terai and duars (and locally up to c. 2100 m. alt.) from Kumaon eastward through Nepal, W. Bengal, Bhutan and western NEFA; western Assam and E. Pakistan. South through Bihar, Orissa, eastern Madhya Pradesh (Bastar dist.), northern Andhra, and Maharashtra (Marathwada) to c. 18°N. lat. Affects dry deciduous sparsely wooded or scrub-and-bush covered hillsides and broken stony country.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 596.

BREEDING. Season, chiefly April to July but struggling over other months as well. Nest and eggs as in 596; normal clutch reported to be of 3 eggs. Average size c. 35 × 27 mm.

MUSEUM DIAGNOSIS. The darkest of the three races.

CUCKOOS

237

MEASUREMENTS

Ba. r, FBI No. 1486, Vol. 4: 185
Plate 52, fig. 5

LOCAL NAMES. *Jāngli tūtā* (Hindi); *Adāvi chiluka*, *Poti* (or *Pūtta*) *chiluka* (Telugu);
Kālli kīrīl (Malayalam); *Pūthāng atti-kukkūlā* (Sinhala).

SIZE. As 596, House Crow ± with longer, broader tail.

FIELD CHARACTERS. As of 596, q.v. See *Museum Diagnosis*.

STATUS, DISTRIBUTION and HABITAT. Resident. Ceylon and peninsular India (Kerala, Tamil Nadu, Andhra, Maharashtra), north approximately to between 18° and 20° N. lat. Affects dry deciduous secondary forest and scrub-and-bush jungle, stony *Euphorbia*-covered hillsides, etc. Plains and foothills, locally up to c. 1000 m. altitude.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 596, q.v.

BREEDING. Season, c. July in Ceylon; chiefly March to June in peninsular India. Nest and eggs as in 596; normally 2. Average size of 20 eggs 33.9 × 26.1 mm. (Baker).

MUSEUM DIAGNOSIS. 'Upperparts brown, washed with dusky green. Throat whitish, foreneck and breast more or less ashy, contrasting with the ferruginous colour of the belly. The entire head often has a distinctly ashy cast' (Whistler).

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♀	147-162	30-34	38-40	c. 214-230 mm. (HW, SA)

Genus *PHAENICOPHAEUS* Stephens

Phaenicopterus Stephens, 1815, in Shaw's *Gen. Zool.* 9 (1): 58

Type, by subsequent designation, *Cuculus pyrrhocephalus* Pennant

Cf. Whistler, H., 1936, *JBNHS* 39: 7

Bill stout, wide at base, compressed anteriorly; culmen curved throughout; upper mandible very high; nostril a narrow horizontal slit close to commissure and parallel with it. Sides of head naked and papillose, the bare skin extending across forehead all round base of upper mandible. No eyelashes. Wing rounded. Tail long, broad, and graduated. Feathers of crown and throat with stiff bristly shafts as in *Rhopodytes*. Sexes alike, differing only in colour of iris.

Only a single species.

CUCKOOS

239

more than a 'hop' from one thicket to another. 'In flight the wings produce a musical hum' (Henry).

FOOD. Recorded as mainly berries of forest trees.

VOICE and CALLS. Usually very silent. Sometimes utters 'short, single yelping whistles; a note like *kok*, imitated by a sucking action of the tongue; and a low, petulant-sounding *kra*' (Henry).

BREEDING. Season, in Ceylon January, April, and May; from mature gonads of specimens evidently also breeds in August-September (or continuingly?). In Kerala April and May (Stewart in Baker). Nest, typical of the malkohas, a shallow saucer of roughly put-together twigs, grass and roots, placed in shrubs in forest with dense undergrowth. Eggs, 2 or 3, chalky white; rounded oval, practically equal at both ends. Average size of 12 eggs 35.8 × 27.0 mm. (Baker). Share of the sexes in the domestic chores, and incubation period, unrecorded.

MUSEUM DIAGNOSIS. As for the genus, q.v. *supra*.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
5 ♂♂	148-156	34-38	c. 30-40	249-286 mm.
4 ♀♀	153-159	34-38	c. 35-36	265-274 mm. (HW, SDR)

COLOURS OF BARE PARTS. Iris ♂ brown, ♀ white. Bill light green or apple-green, dusky at base and about the nostrils. Legs and feet bluish or bluish green.

Genus *CENTROPUS* Illiger

Centropus Illiger, 1811, *Prodromus*: 205. Type, by subsequent designation,

Cuculus aegyptius Gmelin

Genus distinguished from all others of the family Cuculidae in having on the hallux a long, nearly straight hindclaw very much like a lark's (whence sometimes known as Larkheaded Cuckoos); other claws also little curved. Tarsus strong and naked, and longer than normal in the family. Bill deep, moderately large, with

Foot of *C. s. sinensis* (600), × c. 1

culmen much curved. Nostrils partly covered by a membrane. A row of bristles like eyelashes above eye. Wing short and rounded with the primaries scarcely exceeding the secondaries in length. Tail long, broad, and graduated. Feathers of head, neck, and breast stiff and bristly. Sexes alike.

238

CUCULIFORMES

599. Redfaced Malkoha. *Phaenicopterus pyrrhocephalus* (Pennant)

Cuculus pyrrhocephalus Pennant, 1769, *Ind. Zool.*: 6, pl. 6 (Ceylon)
Baker, FBI No. 1484, Vol. 4: 182
Plate 52, fig. 7

LOCAL NAMES. *Māl kōhā*, *Māl kandettā* (Sinhala).

SIZE. Crow-Pheasant ±; somewhat slimmer, with a proportionately longer, graduated tail. Overall length c. 46 cm. (18 in.).

FIELD CHARACTERS. A long and broad graduated-tailed cuckoo similar to the greenbilled malkohas, with a bare crimson-red face.

× c. 1

Adult. Above, black, glossed with metallic green and blue, the crown, nape, and neck flecked with white. Tail-feathers more bronze-green, with white terminal bands. Below, throat and breast black; rest of underparts white. Its most diagnostic features are the bare red face and heavy apple-green bill. Sexes alike.

Young (immature). Bare patch on face brick-red and confined only to round the eye; crown streaked with dull grey. Tail-feathers shorter and less broadly tipped with white. Below, the black feathers on chin and throat streaked with white.

STATUS, DISTRIBUTION and HABITAT. Resident in Ceylon and south Kerala; rare and local. Was long regarded as peculiar to the Island, and reports of its occurrence (and breeding) in south Travancore by J. Stewart (in Baker, 1932-4) were discredited. However, since then the species has been reliably observed at the foot of High Wavy Mountains in the adjoining Tamil Nadu district of Madurai (C. H. Biddulph, 1956, *JBNHS* 53: 697-8) therefore previous doubts probably unjustified. Must undoubtedly be one of the rarest Indian birds. Affects heavy forest, chiefly evergreen, but scattered colonies also found in the Dry zone in Ceylon, low country and hills up to c. 1700 m. Avoids cultivation. Its existence on the Island is seriously threatened by the relentless encroachment upon its native forest habitat for cultivation.

GENERAL HABITS. Similar to *Rhopodytes* (593, 595) qq.v. Keeps singly, or in pairs or small parties to the foliage canopy of trees and shrubs in heavy forest, threading its way deftly through the tangles of leaves and draping twines and disappearing on alarm. Flight feeble and laboured, usually no

600. Common Crow-Pheasant or Concal. *Centropus sinensis sinensis* (Stephens)

Poelophilus sinensis Stephens, 1815, in Shaw's *Gen. Zool.* 9 (1): 51 ('Said to inhabit China' = Ning Po, China, by designation of Stresemann, 1913, *Nov. Zool.* 20: 321)
Baker, FBI No. 1490, Vol. 4: 189
Plate 52, fig. 8

LOCAL NAMES. *Māhākā* (Hindi); *Kūā* (Bengal); *Kūko srai* (Assam), *Kūkūā*, *Dābhi kūkūā* (Assam, Nowgong dist.); *Heakā* (Gulf of Kutch).

SIZE. Jungle Crow ± with long broad graduated tail. Overall length c. 48 cm. (19 in.).

FIELD CHARACTERS. A clumsy glossy black bird with conspicuous chestnut wings, and long, broad, graduated black tail. Sexes alike; female slightly larger.

Young (immature). Variable; some similar to adult, others as follows: Above, barred dark brown and rufous with pale, glistening shafts to the feathers; rump barred blackish brown and pale fulvous; tail black, glossed

¹ This must be used with caution since some examples, especially of *C. s. parroti*, do show a variable amount of chestnut intermixed with the black.

CUCKOOS

241

with green and barred with dull grey or greyish fulvous. *Below*, from chin to under tail-coverts dark brown narrowly barred with dull white. Iris grey, glaucous blue-grey or dull brown.

Juvenile plumage in this species apparently of racial significance since the young of *C. s. sinensis* and *C. s. intermedius* are barred (as above) while those of *C. s. parroti* are not (Humayun Abdullahi, 1956, JBNHS 54: 183-5).

STATUS, DISTRIBUTION and HABITAT. Resident. West Pakistan (Sind, Punjab) and northern India from Kashmir eastward through the Himalayas (terai, duns and foothills, locally up to c. 2100 m. alt.) and the Gangetic Plain to Assam north of Brahmaputra river. Also the duars of Bengal and Sikkim, and foothills of Bhutan. Affects deciduous scrub jungle and tall grassland, and shrubbery in and about cultivation and habitations, freely entering groves, orchards and urban gardens. Flooded tamarisk jungle on riverbanks, irrigated sugarcane fields, and bamboo jungle are also favourite haunts.

Extralimital. Southern China, in provinces of Kwangsi, Chekiang, and Fukien.

GENERAL HABITS. Sedentary, parochial, and largely terrestrial. Keeps singly or in pairs, skulking its way through low undergrowth or stalking along the ground like a pheasant, tail held horizontally, opened and shut from time to time, occasionally cocked and thrown forward right over the back. Works thus in and out of the thickets methodically searching for food. Sometimes suddenly flicks open wings bringing them forward almost to the head — obviously a manoeuvre to stampede lurking prey. Often springs up a foot or more in the air to seize a grasshopper or lizard from an overhanging weed-stem or twig. Walks and runs strongly but is a poor flier, reluctant to leave cover unless pressed, then making a short clumsy flight to the nearest thicket. Clammers with 'hand over hand' action along inclined branches, or ascends into the foliage canopy of trees, hopping with agility from branch to branch and hunting systematically. Volplanes down into undergrowth on alarm.

Pre-copulatory sexual play consists of male strutting grotesquely and chasing female on the ground, and in and out through shrubbery, the latter pretending to flee with tail depressed, wings drooped and occasionally vibrated to the accompaniment of a frequent harsh *cheetaw* or *ske-e-tee-aw*. Sometimes the chase and its culmination take place up in the branches of trees.

FOOD. Predominantly animal. Items commonly recorded are baby mice, bats (occasional), geckos (*Hemidactylus* spp.), skinks (*Mabuya* spp.), 'blood-sucker' lizards (*Calotes* spp.), snakes (*Dryophis mycterizans*), stranded fish, frogs, crustaceans, molluscs, insects, spiders. Highly destructive to eggs and nestlings, especially of ground- and bush-nesting birds (also to small birds caught in low mist nets!). Among insect items the following identified at Pusa Agricultural Research Institute, Bihar: cutworms (*Agrotis* spp. larvae), *Brachytrypes achatinus*, *Opatrum depressum*, *Asystes lateralis*, besides various bugs (Hemiptera), ants (*Camponotus* and *Oecophylla*), grasshoppers and locusts. Occasionally some vegetable matter (grass, leaves, etc.) also found in stomachs (Mason & Lefroy, 1912).

VOICE and CALLS. A deep, resonant *coop-coop-coop-coop* etc. in runs of 6 or 7 (often up to 20 or 30) quickly repeated at the rate of 2 or 3 *coops* per

CUCKOOS

243

SIZE. Jungle Crow \pm with long broad graduated tail. Overall length c. 48 cm. (19 in.).

FIELD CHARACTERS. As of 600, q.v. See Key to the Subspecies and Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident. Assam south of Brahmaputra river, Cachar, Nagaland, Manipur, Mizo (?), Tripura; East Pakistan (Sylhet, Tippera, Chittagong Hill Tracts); up to c. 1200 m. altitude. Affects scrub-and-bush jungle and tall grassland.

Extralimital. Burma north to the Chin Hills, and S. Yunnan south to peninsular Thailand and the Indochinese countries; Hainan I.

GENERAL HABITS, FOOD, VOICE and CALLS. Not significantly different from 600, q.v.

BREEDING. Season, principally mid June to end August. Nest, as of 600, globular, of twigs and grass. Eggs, 3 or 4, chalky white, elliptical. Average size of 50 eggs 35.7 \times 28.6 mm. (Baker). Fledgelings said to leave nest when about a month old.

MUSEUM DIAGNOSIS. Differs from the nominate race (600) only in being smaller.

MEASUREMENTS			
Wing	Bill (from feathers)	Tarsus	Tail

COLOURS OF BARE PARTS. As in 600.

602. Southern Crow-Pheasant. *Centropus sinensis parroti* Stresemann

Centropus sinensis parroti Stresemann, 1913, Nov. Zool. 20: 323 (Ceylon)
Baker, FBI No. 1492, Vol. 4: 192

LOCAL NAMES. *Māhikā* (Hindi); *Jemudu kiki*, *Chemara kiki* (Telugu); *Kalli kaka*, *Chempakam* (Tamil); *Atti kukkula*, *Bū kukkula* (Sinhala); *Uppan*, *Chemboth* (Malayalam); *Kimbhār kōla* (Marathi); *Hokka*, *Chōyāra* (Gujarati); *Hokka* (Gulf of Kutch).

SIZE. Jungle Crow \pm with long broad graduated tail. Overall length c. 48 cm. (19 in.).

FIELD CHARACTERS. As of 600, q.v. See Key to the Subspecies and Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident. Peninsular India south of the range of *C. s. sinensis* (south of the Gangetic Plain) from N. Gujarat, Kutch, and Saurashtra east through Madhya Pradesh, Andhra and Orissa, south through Maharashtra, Mysore, Tamil Nadu and Kerala. Plains and hills, locally to c. 2220 m. altitude. Ceylon (all zones). Affects light forest, scrub-and-bush jungle, grassland, plantations, cultivation and the neighbourhood of habitations.

GENERAL HABITS and FOOD. As in 600, q.v. In addition, recorded feeding on fruits of Yellow Oleander, *Thevetia nerifolia* (Sanjeeva Raj, JBNHS 60: 457).

BREEDING. Season, in peninsular India practically all year, chiefly November to May; in Ceylon chiefly February to April and August-September. Nest and eggs (2 to 4) similar to the northern race (600), but in

242

CUCULIFORMES

second. Usually in duets: as soon as one bird begins calling another within earshot (its mate?) almost invariably joins in. Single calls or short runs reminiscent of langur monkey's *whoop* in distance. Calling most persistent during the breeding season, often commencing at early dawn and sometimes kept up at night. An occasional quick repeated *kūi-kūi-kūi-kūi*, of about half-minute's duration sounding like the oil engine of a village flour mill has been heard, the significance of or provocation for which is not known. During courtship (also when annoyed) utters a medley of harsh, weird croaks and chuckles.

BREEDING. A non-parasitic cuckoo. Season, chiefly June to September. Nest, a large untidy globular structure like a Rugby football, c. 45 \times 35 cm., of twigs and leaves, or mainly leaves of elephant grass or bamboo, with a lateral entrance; sometimes a deep cup with the dome formed by intertwining the surrounding living foliage and creeper stems. Placed within a thick bush or bamboo clump or among the branches of a thorny tree, at moderate heights, usually well concealed amongst tangled vines. Eggs, 3 or 4 (exceptionally 5 and even 6 recorded), broad ellipses, chalky white, becoming yellow-stained as incubation proceeds. Average size of 50 eggs 35.9 \times 28.0 mm. (Baker). Nest-building and incubation by both sexes; incubation period and other details of breeding biology unknown.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.; for subspecies, Key.

MEASUREMENTS				
	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	205-232 (one 195, one 239, one 242)	33-37	58-66	220-262 mm. (Baker)
5 ♂ ♀	from Nepal 193-210	(from skull) 38-41	—	222-254 mm. (BB)

5 σ^7 ♀ from Sindh (in British Museum) Wing 225-239 mm. (Titchhurst).
Weight 1 σ^7 362 gm. (SA).

There is considerable individual variation in size, but in most cases females are larger than males. The significance of this disparity needs to be studied.

COLOURS OF BARE PARTS. Iris bright crimson. Bill, legs and feet black.

MISCELLANEOUS. Flesh of the coucal is relished as an epicurean delicacy in many parts of the country, and widely believed to be a panacea for consumption, asthma and other pulmonary ailments.

601. East Pakistan Crow-Pheasant. *Centropus sinensis intermedius* (Hume)

Centropus intermedius A. O. H. (= Hume), 1873, Stray Feathers 1: 454, in text (Dhooon, Dacca, and Thayetmyo)

244

Ceylon the normal clutch is of 2 or 3 eggs only. Average size of 30 eggs 36.2 \times 26.3 mm. (Baker).

VOICE and CALLS. 'The scold-note used when the bird mobs a lurking snake or owl etc., is an explosive *k'wiss*; and, in courtship, a curious sound is produced — *djoont* — like a stone dropped into deep water, or a tight cork drawn from an empty bottle' (Henry).

MUSEUM DIAGNOSIS. Differs from 600 and 601 in having the interscapulars black instead of chestnut (but see Whistler, 1934, JBNHS 37: 528). Forehead and forehead paler and brownish with little or no gloss; sheen of head, back, and underparts more blue or blue-green than rich purple-blue as in the other two. These characters however show considerable individual variation.

MEASUREMENTS				
	Wing	Bill (from skull)	Tarsus	Tail
♂♂	173-195	37-45	42-57	197-265 mm.
♀♀	178-210	38-45	46-58	223-310 mm. (SA, HW)

Weight 1 σ^7 230 gm. (Rensch).

COLOURS OF BARE PARTS. As in 600.

MISCELLANEOUS. There is a curious folk-belief common to such far-flung parts of the country as Saurashtra and South Kanara (possibly more general) that the crow-pheasant's nest is lined with some particularly valuable (and that the crow-pheasant's nest is lined with some particularly valuable ('life-giving magical') kind of 'grass' known in Kanara as *sānjivānā kāddi* ('life-giving herb') — which can be separated from the rest of the material by throwing it into a stream, whereupon the former will flow against the current!

603. Andaman Crow-Pheasant. *Centropus (sinensis) andamanensis* Beavan

Centropus andamanensis 'Tyler' = Beavan, 1867, Ibis: 321 (Andaman Islands)
Baker, FBI No. 1494, Vol. 4: 194
Plate 52, fig. 10

LOCAL NAMES. None recorded.

SIZE. Jungle Crow \pm , with long broad graduated tail. Overall length c. 48 cm. (19 in.).

FIELD CHARACTERS. Like Common Crow-Pheasant (600) with chestnut wings, but whole head, body and tail brown instead of glistening black. Sexes alike. See Museum Diagnosis.

Young (immature). Above, traces of barring on head, neck, and upper back. Below, barred from chin to vent with pale brown and pale dusky ochre.

STATUS, DISTRIBUTION and HABITAT. Andamans (North, Middle, and South), Great and Little Coco, and Table islands. Nicobars? To what extent, if at all, moving from island to island not known. Affects outskirts of forest, gardens, and cultivated tracts especially sugarcane. Partial to newly ploughed paddyfields and mangrove swamps.

GENERAL HABITS. As of Common Crow-Pheasant (600), q.v. Commonly walks about on the ooze of mangrove swamps in search of food (A. L. Butler, JBNHS 12: 566).

FOOD, VOICE and CALLS. Presumably as in 600; nothing recorded as specifically different.

CUCKOOS

245

BREEDING. Season, mainly mid May to end July, but as in other races not well defined. Nest and site as in Indian birds. Eggs, 2 or 3 — occasionally 4 — also similar. Average size of 30 eggs 34.7 × 28.0 mm. (Baker).

MUSEUM DIAGNOSIS. Whole head and body greyish brown, darker and browner on lower back, rump, vent and under tail-coverts. Tail darker brown towards tip, and conspicuously black-shafted. Scapulars, interscapulars, and wings rich deep chestnut-bay (of variable intensity), the tips of the quills more dusky brown.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	173-195	29-35	52-56	235-242 mm. (Baker)
		(from skull)		
9 ♂ ♀	180-198	30-40	—	228-261 mm. (HA)

COLOURS OF BARE PARTS. As in 600 and other races.

604. Ceylon Coucal. *Centropus chlororhynchus* Blyth

Centropus chlororhynchus Blyth, 1849, Jour. Asiat. Soc. Bengal 18 (2): 805 (Ceylon) Baker, FBI No. 1493, Vol. 4: 193

Plate 52, fig. 9

LOCAL NAMES. Bātū āti-kukkūā, Wāl āti-kukkūā (Sinhala); Chempakam (Tamil).

SIZE. House Crow ± with long broad graduated tail. Overall length c. 43 cm. (17 in.).

FIELD CHARACTERS. Like Common Coucal (600), q.v., but smaller; readily distinguished by pale apple-green (v. black) bill. Sexes alike.

Young (immature) has no distinct plumage (Wait, 1931).

STATUS, DISTRIBUTION and HABITAT. Species peculiar to Ceylon. 'Resident, in moderate numbers, in and confined to the dense scrub jungles and cane brakes of the Wet zone and neighbouring intermediate tracts, to 2500 ft. [c. 750 m.] on the SW. slopes of the hills' (Phillips, 1953). Affects high humid forest with dense undergrowth of dwarf bamboo and other luxuriant herbage.

GENERAL HABITS and FOOD. Similar to Crow-Pheasant (600), q.v., but very shy and elusive and oftener heard than seen. Its existence now endangered by the rapid destruction of its specialized habitats for agriculture.

VOICE and CALLS. Similar in character to Common Crow-Pheasant's but apparently quite distinctive and unmistakable with it: 'usually only two- or three-syllabled, deeper, and with a sonorous, mournful quality — hoo-poop, hoo-poop-poop — the poop being lower-pitched than the hoo' (Henry).

BREEDING. Season, January to July. Nest, globular or domed, of twigs, roots and grass, lined with green leaves and supple green twigs. Placed in a thorny bush c. 1½ to 2 m. from the ground, inside deep evergreen forest. Eggs, 2 or 3, chalky white, typical of the crow-pheasants. Average size of 9 eggs 34.7 × 27.0 mm. (Baker).

MUSEUM DIAGNOSIS. Head, body, and tail black, glossed with purple, passing on the neck, upper back, and breast into coppery bronze. Wing-coverts, scapulars, and interscapulars deep chestnut-bay; tips of quills dusky; wing-lining blackish.

CUCKOOS

247

VOICE and CALLS. A double series of notes, *whooh*, *whooh*, *whooh*, *whooh* followed by a pause of 4 or 5 seconds, then *kurook*, *kurook*, *kurook*, *kurook*; the *whooh*s decidedly ventriloquistic. Therefore, 'When searching for the caller one must take no notice of the *whooh* but wait for the *kurook*' (J. A. Gammie, 1877, SF 5: 385). Apparently both sexes call from bush-tops. The neck and body are drawn together, the body-feathers slightly fluffed out raising or arching the back, and the tail is depressed. At every *whooh* the body throbs violently as if in agony; but the bill remains closed and hardly any movement of the throat is perceptible. After the *whooh*s the bird seems greatly relieved; it stretches itself out, the feathers are sleeked, and it utters the *kurook* notes with open bill and throbbing throat, with no suggestion of ventriloquism (Gammie).

BREEDING. Season, May to September, chiefly after onset of rains in June. Nest, similar to that of Common Coucal but smaller; a domed, oval structure like a Rugby football in shape, c. 25 × 20 cm. with a lateral entrance-hole; of twigs, grasses, and leaves with the living grass blades of the substrate often worked into the dome; occasionally lined with green leaves. Usually placed less than 1½ metres or so above the ground in a dense bush standing in grassland, or among tussocks of grass or reeds. Eggs, 3 or 4, chalky white, smaller replicas of those of the Common Coucal. Average size of 50 eggs 28.2 × 23.8 mm. (Baker). Both sexes take part in nest-building, incubation, and tending the young. Incubation period and other details unknown.

MUSEUM DIAGNOSIS. See Key. Tail black glossed with green, tipped narrowly with white or rufous and faintly cross-rayed. Scapulars, interscapulars and wings chestnut, the tips of the quills, and the tertiaries, darker and browner, highlighting the paler chestnut shafts by contrast.

For details of juvenile plumage and description of nestling see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	137-174	22-26	36-37	156-211 mm. (Baker)

Specimens recently collected in Nepal give:

	Wing	Bill (from skull)	Tarsus	Tail
5 ♂ ♂	137-148	25-27	—	163-181 + mm. (3 msd.)
5 ♀ ♀	161-169	28-31	—	180-200 mm. (2 msd.) (BB)

More material is needed from SW. India to verify that the race there is in fact *bengalensis* as presumed. 5 unsexed and 1 ♀ from 'Travancore' in the British Museum collection, and 1 ♀ recently collected there, measure:

	Wing	Bill (from skull)	Tarsus	Tail
	168-173	27-30	43 (1)	205-209 mm. (3 msd.) (HW)

COLOURS OF BARE PARTS. Iris crimson. Bill black. Legs and feet slaty black to black.

246

CUCULIFORMES

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♂	160-172	38-44	45-47	215-240 mm. (Baker)
♀ ♀	174-182			
		(from skull)		
1 ♂	179	48.5	48	225 mm.
1 ♀	160	43	45	223 mm. (HW)

COLOURS OF BARE PARTS. Iris deep red to crimson. Bill apple-green, blackish at base and about nostrils. Legs and feet black; claws dusky.

605. Lesser Coucal. *Centropus loulou bengalensis* (Gmelin)

Cuculus bengalensis Gmelin, 1788, Syst. Nat., 1 (1): 412 (Bengal)

Cf. Whistler, H. & Kinnear, N. B., 1935, JBNHS 37: 528

Baker, FBI No. 1495, Vol. 4: 194

Plate 52, fig. 6

LOCAL NAMES. Chhōto-kūkō (Bengal); Ūlū kūkūhā (Assam); Nyong (Lepcha); Kynk-hyok (Bhutea); Yāri ūppān (Malayalam).

SIZE. House Crow —; with a long broad graduated tail. Overall length ♂ c. 33 cm. (13 in.), ♀ c. 37 cm. (14½ in.).

FIELD CHARACTERS. Similar to the Common Crow-Pheasant (600), glistening blue-black with chestnut wings, but conspicuously smaller and with the tail-feathers tipped whitish. Sexes alike; female larger.

Young (immature) in one stage, dark brown above, mottled and barred with rufous on wings and tail. Below, rufescent white with dusky bars. On a casual sighting young bird could be confused with Sirkeer Cuckoo, but absence of latter's cherry-red bill always diagnostic.

STATUS, DISTRIBUTION and HABITAT. The submontane tracts of the Himalayas — terai, bhabar, duns, and duars — and locally up to c. 1500 metres, from about Dehra Dun eastward through Nepal, Sikkim, Bhutan to Assam north and south of the Brahmaputra, Nagaland, Manipur, Mizo (?); East Pakistan. Widely but locally distributed in the Peninsula from the Gangetic Plain (Uttar Pradesh, Bihar, West Bengal) southward through Mysore, Kerala, and Tamil Nadu. Confined to a specialized habitat — stretches of tall grassland and dense scrub jungle bordering forest, and reed-beds and 'seas' of elephant grass on the edge of swamps and jheels and in flood plains; thus absent from large tracts of country. In some areas has been presumed to be migratory, but not proven. Occurrence in Ceylon doubtful.

Extralimital. Burma, S. Yunnan, south to Tenasserim, Thailand, and the Indochinese countries; Hainan I.

GENERAL HABITS and FOOD. Not significantly different from the Common Crow-Pheasant (600), q.v. Flight weak, laboured, and ill-sustained — several rapid wing-beats followed by a glide. 'Feeds almost exclusively on grasshoppers' (Gammie; Sikkim).

woowooowooowooowoo or *woioioioioio*...

kek, like a variant of 636.

Soft, musical *oo... ūk; oo... ūk, oo... ūk*.

Shrill, plaintive *piu* repeated every few seconds.

Harsh screechy *chirurr-chirurr-chirurr*, and variants.

Clear long-drawn *huu* at intervals, and variants.

Loud quavering *ceric chūhua-aa* (breeding) and mellow metallic single hoot (non-breeding).

Mellow, musical, hollow-sounding *tok...*

tū-hoo (*tok* in undertone).

Sonorous hoot *hūhū-hōōō*.

Loud *hoo... hoo... hoo-ho-ho-hoo*.

Subfamily TYTONINAE: Barn Owls

Genus TYTO Billberg

Tyto Billberg, 1828, Syn. Faun. Scand. 1, pt. 2, tab. A. Type, by monotypy,

Strix flammea auct. = *Strix alba* Scopoli

No ear-tufts. Facial disc well developed and large, entirely surrounded by a ruff of stiff feathers. Bill straight at base, compressed and comparatively weak. Nostrils oval. Legs long, the upper part of the tarsus covered with feathers which pass into bristles on lower tarsus and upper surface of toes. Middle toe scarcely longer than inner, with the claw expanded and pectinate on the inner side. Wings very long and pointed, exceeding tail in length: 2nd primary (as.) longest, first subequal. Tail moderately long.

Key to the Species

Upper surface speckled; tarsus less than 75 mm.	<i>T. alba</i>	249
Upper surface spotted; tarsus over 75 mm.	<i>T. capensis</i>	252

Wing under 270 mm.; general colour deeper	<i>T. a. deroepstorffi</i>

BARN OWLS

251

FOOD. Small birds like house sparrows, bats, etc. but predominantly rats and mice; thus, as a species, highly beneficial to agricultural economy.

VOICE AND CALLS. A variety of discordant long-drawn shrieks and chuckles, and weird snoring and hissing notes; a castanet-like bill-snapping when angry. Particularly noisy in the breeding season.

BREEDING. Season, undefined, covering practically the entire year, the peak periods varying locally. Nest, none built; occasionally the eggs deposited on a layer of, or amongst, cast-up pellets and bony debris of victims—in holes or niches in ruins, in the space between ceiling and roof of a building whether deserted or occupied, in hollows in ancient tree-trunks, and the like. The same sites are used in successive years, and if left undisturbed tend to become traditional. Eggs, 4 to 7, white, fine-textured and smooth; short, broad ellipses, somewhat less rounded than most other owls' eggs. Average size of 38 eggs 40.7 × 32.5 mm. (Baker). Laid at about 48-hour intervals, incubation often commencing with first egg, thus great disparity noticeable among young of the same brood. Incubation evidently by female alone; period elsewhere recorded as 32-34 days. Both parents tend the young.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.; for plumages and structure (also bionomics), Witherby, 1938, 2: 343-6 (for nominate race).

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	275-322	30-32	c. 68-77	119-127 mm. (Baker)
		(from skull)		
10 ♂♂	262-303	34-37	70 (1)	111-123 mm.
5 ♀♀	278-315	35-37	60-70	114-125 mm. (HW, SA)

COLOURS OF BARE PARTS. Iris deep brown, hazel, or black. Bill fleshy white to fleshy horny; cere more flesh coloured. Legs and feet pale fleshy brown; claws darker.

607. Andaman Barn Owl. *Tyto alba deroepstorffi* (Hume)

Strix DeRoepstorffi Anonymous = Hume, 1875, Stray Feathers 3: 390 (Aberdeen, South Andaman Is.)

Baker, FBI No. 1637, Vol. 4: 386

LOCAL NAMES. None recorded.

SIZE. House Crow —; length c. 36 cm. (14 in.).

FIELD CHARACTERS. As of 606, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Evidently a very scarce resident in the Andaman Is. (Port Blair; a specimen collected on South Cinque island (Abdulali, 1971, JBNHS 68: 403); not recorded from the Nicobars.

GENERAL HABITS, FOOD, VOICE AND CALLS. As of the Indian bird (606) q.v.

BREEDING. Unknown.

MUSEUM DIAGNOSIS. See Key to the Subspecies. Much darker overall than *stertens*. Facial disc very rufescent; grey of upperparts replaced by dark brown, and ochre by rich rufous. Some grey stippling retained on the tips of wing- and tail-quills. Underparts, axillaries and under wing-coverts deep brownish rufous.

606. Indian Barn Owl. *Tyto alba stertens* Hartert

Tyto alba stertens Hartert, 1929, Nov. Zool. 35: 98 (Cachar)

Tyto alba crypta Koelz, 1939, Proc. Biol. Soc. Washington 52: 80

(Londa, Bombay Presidency)

Baker, FBI No. 1636, Vol. 4: 385

Plate 54, fig. 16

LOCAL NAMES. *Kuraya*, *Kareil*, *Būri churi* (Hindi); *Lakshmi pechi* (Bengal); *Chēdd* or *Chūdd* (Marathi); *Rici deri* (Gujarati); *Chāru kūrūri* (Tamil); *Chaoa pitta* (Telugu); *Bakamūnā* (Sinhala); *Veli munga* (Malayalam); *Madoosa* (Bihar); *Chūghū* (Damoh, Madhya Pradesh).

SIZE. House Crow —; length c. 36 cm. (14 in.).

FIELD CHARACTERS. A typical owl with large round head and a conspicuous ruff of stiff feathers surrounding a

× c. 1/2

comically pinched (heart-shaped) white monkey-like facial disc. Above, golden buff and grey, finely stippled with black and white. Much yellowish brown about the shoulders and on wings. Below, silky white, more or less tinged with buff and usually spotted dark brown. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Resident.

West Pakistan (Baluchistan, Sind, Punjab) and all India from Jammu east-

ward through the Gangetic Plain to Bengal,

Assam, Nagaland and Manipur, south throughout the Peninsula to Kanyakumari; East Pakistan; Ceylon (rare, and restricted to Jaffna and Aripo districts on the NW. coast). Recorded from Nepal in c. 1879 (Scully, SF 8: 229) but not met there by recent investigators, nor in Sikkim or Bhutan. Affects the neighbourhood of cultivation and human habitations chiefly in the plains and peninsular hills to c. 1000 m.—ruins of ancient forts, crumbling archaeological structures, caves, disused wells, and buildings both deserted and occupied in towns and city suburbs.

Extralimital. Probably northern Burma, where the limits of this form and the prevailing *javanica* not known. The species in numerous races has an almost global distribution.

GENERAL HABITS. Largely crepuscular and nocturnal, less because of inability to withstand the glare than to escape the persecution invariably meted out by crows and other birds as soon as it shows itself in daytime. Is capable of flying in broad sunlight without apparent discomfort and has even been observed hunting on a sunny morning, flying purposefully to and fro 3 or 4 metres above a grass field, hovering for up to 30 seconds like a Blackwinged Kite (*Elanus*), before pouncing on ground prey. Usually spends the day standing upright, dozing with shut eyes, singly or in pairs, in a dark hollow in some ruin or ancient tree, or under the eaves or roof of a building, sallying forth at dusk to feed heralded by a harsh prolonged screech. The ground under such diurnal roosts is usually strewn with cast-up pellets of undigested skulls and bones of its victims. Often seen flying ghost-like over the blaze of a city's illumination after dark, uttering its distinctive screech from time to time.

STRIGIFORMES

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	250-264	c. 32	c. 61	c. 113 mm. (Baker)

COLOURS OF BARE PARTS. Unrecorded.

608. Grass Owl. *Tyto capensis longimembris* (Jerdon)

Strix longimembris Jerdon, 1839, Madras Jour. Lit. Sci. 10: 86 (Neilgherries, India)

Baker, FBI No. 1638, Vol. 4: 387

Plate 54, fig. 17

LOCAL NAME. *Sun ūlū sorūi* (Assam).

SIZE. House Crow —; length c. 36 cm. (14 in.).

FIELD CHARACTERS. An unmistakable first cousin of the Barn Owl, found only in tall grassland habitats. Above, dark brown minutely spotted with white; below, white with scattered brown spots. Facial disc white or pinkish rusty white bordered by a dark brown ruff; a prominent blackish spot in front of each eye. Tail largely white and buff, cross-banded with brown. Tarsus very long, slender, and tightly feathered, as though clad in underpants or *churidar pajamas*! In flight the bird looks very white overall with brownish patches. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Resident. The submontane tracts of the Himalayas from at least Dehra Dun eastward through the terai and duars and Gangetic Plain to Bengal, and Assam (north and south of Brahmaputra river), hills and plains. Probably also Manipur and East Pakistan, and in appropriate grassland biotopes in the terai and duars of Nepal, Sikkim, and Bhutan. Recorded from several localities in the Peninsula, e.g. Chota Nagpur, Madhya Pradesh (Balaghat, Raipur), and in south India (up to c. 1800 m. in the hills) from Tamil Nadu (Nellore, Nilgiris, Palni), Mysore (Brahmagiris), and Kerala (Munnar, High Range). Not Ceylon. Affects tall grass jungle, open grassland on flood-plains (swamp deer and florican country) and in depressions among low rolling hilltops.

Extralimital. Burma, North Vietnam (D. Amadon, 1959, JBNHS 56: 344-5).

GENERAL HABITS. Crepuscular and nocturnal. Almost entirely terrestrial; spends the daytime standing bolt upright and dozing in some small opening amidst tall grass, flying a short distance when disturbed and dropping into the cover again. Hunts silently and ghost-like at night, presumably hovering like Barn Owl to spy prey among the heavy grass. Usually keeps singly or in pairs, but as many as six on the wing at the same time have been observed in northern Uttar Pradesh when florican shooting (A. Anderson, 1876, SF 4: 253).

FOOD. Chiefly field mice; in addition, as shown by cast-up pellets, locusts, grasshoppers and cicadas; once a bustard quail (*Turnix*). Doubtless feeds regularly on small ground birds as well as reptiles.

VOICE AND CALLS. Not specifically recorded; according to Baker weird screeches similar to Barn Owl's.

BREEDING. Season, overall October to March (chiefly October to December) in N. India and Kerala; once July in Cachar (Baker). Nest, a

BARN OWLS

253

pad or mat of flattened-down grass amidst tall grassland, canopied by the arching surrounding growth. Eggs, 4 to 6, pure white with a smooth matt surface, indistinguishable from eggs of Barn Owl. Average size of forty 39.9 × 32.7 mm. (Baker). Period of incubation, and share of the sexes in the domestic chores, unknown.

MUSEUM DIAGNOSIS. See Key; for details of plumage Baker, loc. cit.

Chick (in down) 'Fulvous-rufous' (Baker).

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	305-348	c. 36	86-94	114-125 mm. (Baker)

COLOURS OF BARE PARTS. Iris hazel to deep brown. Bill fleshy white to fleshy horny; cere pinkish. Legs and feet dark fleshy brown to almost blackish brown; claws horny brown.

Genus PHODILUS G. St-Hilaire

Phodilus Geoffroy Saint-Hilaire, 1830, Ann. Sci. Nat. 21: 199. Type, by original designation and monotypy, *Strix badius* Horsfield

Facial disc distinct but incomplete above the eyes. Bill weak and compressed. Ear orifice of fair size but smaller than eye; no operculum. Wings rounded; 4th and 5th primaries (as.) subequal and longest. Tail short. Tarsus feathered throughout; inner toe longer than middle toe; middle claw pectinate as in *Tyto*.

Contains a single Oriental species of which two races occur within our limits.

609. Sikkim Bay Owl. *Phodilus badius saturatus* Robinson

Phodilus badius saturatus Robinson, 1927, Bull. Brit. Orn. Cl. 47: 121 (Native Sikkim) Baker, FBI No. 1640, Vol. 4: 390

Plate 54, fig. 15

LOCAL NAMES. None recorded.

SIZE. Pigeon—; length c. 29 cm. (11½ in.).

FIELD CHARACTERS. A small, dainty chestnut-bay owl with short ear-like tufts projecting above sides of head. Above, chestnut, spotted with black and buff. Outer webs of first two primaries barred white and black. Tail chestnut, barred with black. A broad frontal tract (forehead) and facial disc vinous-pink surrounded by a white-ruff tipped black and chestnut. The patch of chestnut feathers round each eye is a striking feature. Below, vinous-pink

610. Ceylon Bay Owl. *Phodilus badius assimilis* Hume

Phodilus assimilis Hume, 1877, Stray Feathers 5: 138 (Ceylon) Baker, FBI No. 1641, Vol. 4: 391

LOCAL NAMES. *Bassā* (Sinhala; a general term for all small owls); *Anāai* (Tamil).

SIZE. Pigeon—; length c. 29 cm. (11½ in.).

FIELD CHARACTERS. As of 609, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Race peculiar to Ceylon. A very scarce resident in the low-country Wet zone and Hill zone to c. 1200 m. Less than a dozen specimens have so far been taken in the Island.

GENERAL HABITS, FOOD, VOICE and CALLS. Even less known than of 609.

BREEDING. Three young birds once taken from a nest in a tree-hole, in November (1876), exhibited great disparity in size indicating that as with some other owls the eggs had been laid at intervals of several days and incubation had probably commenced from the first egg (Henry).

MUSEUM DIAGNOSIS. Differs from 609 in being much darker, almost chestnut-brown, above and more freely marked with black. Below, the black spots are double, one behind the other along the shaft, divided by, and edged with, whitish.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	197-203	c. 30	c. 47	81-89 mm. (Baker)

COLOURS OF BARE PARTS. Iris dark brown. Bill greenish white. Feet pale whitish green; claws pale ash (Whyte).

610a. Peninsular Bay Owl. *Phodilus badius ripleyi* Hussain & Khan

See Appendix

Subfamily STRIGINAE: Owls

Genus OTUS Pennant

Otus Pennant, 1769, Ind. Zool.: 3. Type, by monotypy, *Otus bakkamoena* Pennant

Contains small owls of extremely beautiful vermiculated and speckled grey, brown, and rufous plumage, with well developed agrettes or ear-tufts. Head proportionately large. Bill rather small; nostrils round, pierced in the anterior margin of the cere. Wing long but of variable shape. Tail moderate, rounded at the ends. Tarsus fully feathered or nearly so. Sexes alike, but juvenile plumage different from adult.

Cf. Delacour, J., 1941, *Zoologica* 26: 133-42; Deignan, H. G., 1950, *Auk* 67: 189-201.

254

STRIGIFORMES

spotted with black and white except on foreneck and down centre of abdomen to under tail-coverts. Legs fully feathered. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Resident; apparently very rare. Nepal, Sikkim, Bhutan (?), Assam north and south of Brahmaputra river, Nagaland, Manipur. Confined to heavy evergreen forest in the submontane tracts and foothills, locally up to c. 1500 metres alt.

Extralimital. N. Burma, N. Thailand, N. and S. Vietnam (Peters).

GENERAL HABITS. Very little known as the bird is strictly nocturnal and seldom seen. Is greatly incommoded by, and practically helpless in day-light; spends the daytime lurking in dark holes and hollows in tree-trunks etc. '... hunts from a perch, but sharpens its gaze by rocking the head rhythmically from side to side [like a pendulum] over a small amplitude (almost hypnotic to the observer), and it flies for its captures through dense stands of young trees beneath the forest canopy. Uniquely short, rounded wings facilitate this rapid flight by which the bird threads its way easily through the maze of vertical stems.' Perches sideways on stems of saplings, its huge feet enabling the vertical stalk to be grasped in the manner of a tit clinging to an upright twig (J. T. Marshall, Jr., 1966, *The Natural History Bulletin of the Siam Society* 21 (3-4): 238).

FOOD. On evidence of cast-up pellets, mainly small mammals, birds, lizards, frogs, and beetles and other large insects. An example picked up dead in heavy forest disclosed the cause to be the wing bone of a bat it had swallowed protruding through the stomach! (Hume, SF 11: 19).

VOICE and CALLS. Very imperfectly known. According to Baker a single soft hoot; also much noisy caterwauling during the breeding season, and a hissing when approached at nest. 'A loud 3-noted whistle reminiscent of someone calling his dog, the birds answering each other in the forest' (H. Elliott McClure in *epist.*, for nominate race).

An entirely different call, also of the nominate race, described by another observer as 'kwankwit-kwankwit-kek-kek-kek heard most when flying in complete darkness' (J. Cairns, 1955, *Malayan Nature Journal*, Vol. 10).

BREEDING. Season, March to May. Nest, an unlined hollow in a tree-trunk or a rotten stump between c. 2 and 5 metres up; the same site used year after year, the hollow becoming littered with cast-up food pellets. Eggs, 3 or 4, sometimes 5, pure white roundish ovals with a smooth matt surface, typical of the owls. Average size of 30 eggs 34.5 × 30.0 mm. (Baker). Incubation period, share of the sexes in the reproductive chores, and other points concerning breeding biology completely unknown.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.; for subspecies, Key.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	214-237	30-32	47-48	92-97 mm. (Baker)

COLOURS OF BARE PARTS. Deep brown or black. Bill creamy yellow. Legs and feet clay-brown or yellowish brown, claws paler.

Ephialtes Huttoni Hume, 1870, Rough Notes, pt. 1, no. 2: 393 (Near Mussoorie, Garhwal and below Simla, i.e. Jerripani, Mussoorie) Baker, FBI No. 1673, Vol. 4: 429

LOCAL NAMES. None recorded.

SIZE. Myna ±; length c. 18-20 cm. (7-8 in.).

FIELD CHARACTERS. A pretty little nocturnal greyish brown 'eared' forest owl, hardly ever seen except by flashlight after dark, and then rather difficult to distinguish from the many other similar species. Recognized mainly by its distinctive calls, q.v.

Adult. Above, speckled greyish brown, conspicuously marked on crown and nape with twin spots of black and white. Wing- and tail-quills brown with numerous pale bands. Face whitish brown indistinctly barred, surrounded by a buff coloured ruff. Below, speckled brown on white with indistinct paler stippling on breast and abdomen. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Resident in the western Himalayas from about Murree in W. Pakistan eastward through Himachal Pradesh, Garhwal and Kumaon to central Nepal, where intergrading with the nominate race (612) occurs. Affects oak, rhododendron, blue pine and deodar forest between c. 600 and 2600 metres alt.

MUSEUM DIAGONOMI. Spots on scapulars buff; tarsus fully feathered.

OWLS

261

General aspect of plumage pale grey streaked with black, more boldly above; hardly ever with any rufous tint as almost always the case in *O. scops scops* and *O. s. pulchellus*. For details see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂ ♀	150-161	17-18 (from feathers)	c. 34	78-82 mm. (Baker)

Weight 1 ♂ (December) 110 gm. — BNHS.

COLOURS OF BARE PARTS. Iris bright yellow. Bill horny yellow; culmen and tip darker, lower mandible paler. Feet grey; claws dark horny; soles paler.

Strix pulchella Pallas, 1801, *Reise Russ. Reichs* 1: 456 ('Copiosius in australioribus ad Volgam, Samaram: laicum')
Baker, FBI No. 1677, Vol. 4: 433

LOCAL NAMES. None recorded.

SIZE. Myna —; length c. 19 cm. (7½ in.).

FIELD CHARACTERS. A small slim owl, delicately vermiculated greyish brown, with feathered legs and ear-tufts, more conspicuous when erected. Sexes alike. See Keys to the species and subspecies, and Museum Diagnosis.

Individuals of the different forms difficult to identify except in the hand, and even then not always with confidence. Many have dark and light phases (rufous and grey) which tend to add to the uncertainty. Calls also somewhat variable, and in many cases identical; thus not completely dependable as pointers.

STATUS, DISTRIBUTION AND HABITAT. Possibly only a winter straggler to Sind (Karachi, Hyderabad). Summer visitor (or resident?) in some numbers in northern Baluchistan (Loralai — March); breeding for certain in the juniper forest at Ziarat (c. 2500 m.), and doubtless elsewhere (Ticehurst, JBNHS 34: 474).

Vagrants have twice been taken in Bombay City, in September (1891) and October (1925), the latter perched on a hat-peg within a living room! (SA & HA, JBNHS 40: 368).

OWLS

263

(?), chiefly the submontane tracts; locally up to c. 1500 m. The Gangetic Plain south to Madhya Pradesh and Orissa (to c. 19°N.), east to Assam north and south of Brahmaputra river; Nagaland (?), Manipur, East Pakistan. Affects forest (deciduous and evergreen), orchards, groves of densely foliated trees around cultivation, etc.

GENERAL HABITS AND FOOD. As in 614 and 615, q.v.

VOICE AND CALLS. A monotonous 3-noted 'song' variously described as *kirrok-look*, *witk-tuk-tah*, and *witk-chug-chug* somewhat resembling a barbet's call, repeated at short intervals endlessly 'in a very regular and rhythmic manner, like the swinging of a giant pendulum or the working of a pump engine' and audible several hundred metres away (Osmaston, Whistler). 'Sings' after dark, all through the night; noisier in the breeding season.

BREEDING. Season, c. mid February to April-May. Nest, a hollow in a tree-trunk or hole in a ruined wall, at moderate heights. Eggs, 3 or 4 (occasionally 5?), white, smooth-textured, roundish ovals. Average size of 10 eggs 32.8 × 27.0 mm. (Baker). Share of the sexes in the reproductive chores, and incubation period, unknown.

During the breeding season both sexes fly quickly into the air off some elevated perch and then fly round in circles with wings stiffly extended, both birds being sometimes in the air together, squawking softly in a note I have heard at no other time' (Baker).

MUSEUM DIAGNOSIS. Very similar to *O. s. pulchellus* (615) but browner and with a different wing formula: 1st primary (as.) equal to 8th or between 7th and 8th. Above, more finely vermiculated with fewer central streaks; these sometimes absent except on forehead and crown. Below, also less streaked and rather more barred. The rufous phase varies from a mere rufescence overall to almost bright cinnamon-bay with no vermiculations on the upperparts and only a few black streaks on forehead and crown. For details of the rufous plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂ ♀	137-154	(from feathers) 16-17	25-26	61-71 mm. (Baker)

Wing ♂ ♀ 132-158 mm. (Ticehurst).

Weight 1 ♂ 79 gm. (SDR).

COLOURS OF BARE PARTS. Iris pale yellow, golden yellow, or dark brown (age?). Bill horny green or horny yellow, tipped blackish. Feet dingy yellowish flesh or fleshy grey.

617. Peninsular Scops Owl. *Otus scops rufipennis* (Sharpe)

Scops rufipennis Sharpe, 1875, *Cat. Bds. Brit. Mus.* 2: 60 (Eastern Ghats, Madras)
Baker, FBI No. 1678, Vol. 4: 434
Plate 54, fig. 3

LOCAL NAMES. *Chius gubā*, *Terrā chius gubā* (Telugu); *Nāthi* (Malayalam).

SIZE. Myna —; length c. 19 cm. (7½ in.).

FIELD CHARACTERS. As for *O. s. sunia* (616). See Keys and Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident. Peninsular India south of the range of *sunia* (616) from northern Maharashtra (Khandesh, c. 21°N.),

262

STRIGIFORMES

Extralimital. 'Breeds in Russia east of long. 35°E. and lat. 56°N.; Caucasus; SW. Asia north to the upper Irtysh, east to Krasnoyarsk and south to the Kirghiz Steppe, Ferghana, Tarbagatai and the Altai. Winters in the upper Nile Valleys...' (Peters).

GENERAL HABITS. As common to all scops owls, e.g. 614. Entirely nocturnal, retiring during daytime into hollows in tree-trunks and thickly foliated branches, standing upright and attenuated with sleeked plumage and half-shut eyes. Emerges at dusk when almost dark and withdraws into seclusion again in the twilight of dawn. Thus seldom seen, and its habits remain largely unknown. In Europe (nominate race) has been observed bringing an ortolan bunting to nest young in sunny midday (Deshayes, in *épist.*). Calls intermittently throughout the night.

FOOD. Beetles, grasshoppers, and other insects; also mice, small birds, lizards, etc.

VOICE AND CALLS. See under 614. Another observer (Cheeseman, Iraq) says the call resembles 'the tinkling of a small brass bell and, as the birds seldom have exactly the same note, the combined effect of several is like an erratic peal of small bells'.

BREEDING. No details from Baluchistan. Elsewhere season April to June. Nest, holes in trees, old walls and buildings, etc. Eggs, 3 to 6 white, roundish ovals. Average size of 44 eggs 31.32 × 27.02 mm. (Jourdain in Baker, FBI).

MUSEUM DIAGNOSIS. Alleged to average a trifle larger and to be more deeply coloured than nominate *scops* of Europe and W. Asia, but is in fact doubtfully distinguishable from it. For description of plumages and structure (also bionomics) of *O. s. scops* see Witherby, 1938, 2: 335-8.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂ ♀	150-158	(from feathers) 16-17	c. 26	66-71 mm. (Baker)

COLOURS OF BARE PARTS. Iris pale to deep golden yellow. Bill dusky greenish yellow, darker on culmen and tip. Feet pale fleshy or fleshy grey.

616. North Indian Scops Owl. *Otus scops sunia* (Hodgson)

Scops sunia Hodgson, 1836, *Asiat. Res.* 19: 175 (Nepal)
Otus sunia khasiensis Koelz, 1954, *Contrib. Inst. Regional Exploration*, No. 1: 27 (Mawphlang, Khasi Hills)
Baker, FBI No. 1680, Vol. 4: 435

LOCAL NAMES. *Chaghād kūriāl*, *Sūyā kūriāl* (Nepal); *Dundul* (Himachal Pradesh).

SIZE. Myna —; length c. 19 cm. (7½ in.).

FIELD CHARACTERS. A small, slim, 'eared' owl, very like 615 but browner; highly variable with dark, rufous, and greyish phases. Sexes alike. Sight records not reliable. See Keys and Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. The lower Himalayas (from the Afghan frontier in West Pakistan eastward through Chitral, Kashmir, Himachal Pradesh, Garhwal, Kumaon, Nepal, Sikkim, Bhutan and NEFA

264

STRIGIFORMES

southeast at least to Madras (northern limit in Andhra Pradesh undetermined), including Mysore and Kerala; chiefly the ghats and associated hill ranges. Affects forest (deciduous and evergreen), and groves of trees around hill cultivation and settlements etc.

GENERAL HABITS, FOOD. As in *O. s. sunia* (616), q.v.

VOICE AND CALLS. Not specifically described; presumably the same as *sunia*'s, with which also the call of the Ceylon race *leggeri* is identical.

BREEDING. Not recorded.

MUSEUM DIAGNOSIS. Differs from *O. s. sunia* in being smaller, and with a different wing formula: 1st primary equal to or longer than 5th. Coloration very variable; cannot be separated on this character from *sunia*, and like it also has a cinnamon-bay phase.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂ ♀	122-135	(from feathers) 17-18	25-26	52-62 mm. (Baker)

Wing ♂ ♀ (123, 124) 129-135 mm. (Ticehurst).

COLOURS OF BARE PARTS. As in 616.

618. Ceylon Scops Owl. *Otus scops leggeri* Ticehurst

Otus sunia leggeri Ticehurst, 1923, *Ibis*: 242 (Ceylon). New name for
Scops minutus Legge, preoccupied
Baker, FBI No. 1679, Vol. 4: 434

LOCAL NAMES. *Pēnchi kussā* (Sinhala); *Sinnā d-dai*, *Nāthi* (Tamil).

SIZE. Myna —; length c. 18 cm. (7 in.).

FIELD CHARACTERS. As for *O. s. sunia* (616), q.v. See Keys and Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident. Race peculiar to Ceylon. Scattered, in small numbers, throughout the lowlands and lower hills to c. 1350 m.; more plentiful in the jungle districts of the Eastern Province than elsewhere (Phillips).

GENERAL HABITS. Little known; chiefly as in *O. s. sunia* (616) q.v. 'It is strictly a forest bird, spending the day roosting in some dense tangle of creepers, dark foliage, etc. If alarmed by the approach of an intruder it erects its ear-tufts, contracts its plumage until it assumes the semblance of a snag of wood, and watches the enemy through nearly closed eyes; in this pose it is almost indistinguishable as an inanimate object' (Henry).

FOOD. Mainly beetles and other insects.

VOICE AND CALLS. 'A loud monotonously repeated *tēk*, *toē toēk* . . . *tēk*, *toē toēk*, etc. [*Wōok*, *toēk-toēroo* . . . *toēk*, *toēk-toēroo*, etc. — Phillips] (the first syllable *tēk* being much less loud than the others) which continues for long periods at night' (Henry). The call is in fact identical with that of both *sunia* and *rufipennis*.

BREEDING. Season March-April. No other details recorded; presumably not different from Indian birds.

OWLS

265

MUSEUM DIAGNOSIS. Wing formula as in *rufipennis*. The smallest and darkest of the Indian forms; like them it also has a cinnamon-bay phase.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	119-127	17-18	20-21	49-54 mm. (Baker)

Wing ♂ ♀ 118-127 mm. (Ticehurst).

COLOURS OF BARE PARTS. As in 616 and the other races.

618a. Andaman Scops Owl. *Otus scops modestus* (Walden)

Scops modestus Walden, 1874, Ann. & Mag. Nat. Hist. (4), 13: 123
(Port Blair, South Andaman Island)
Baker, FBI No. 1681, Vol. 4: 437

LOCAL NAMES. None recorded.

SIZE. Myna —; length c. 18 cm. (7 in.).

FIELD CHARACTERS. As for *O. s. sunia* (616), q.v. See Keys and Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Very little known. Apart from the type there is one other specimen (in the U.S. National Museum) and 5 in American Mus. of Nat. Hist., New York all collected at Port Blair in the Andamans, May, September, December. 'Doubtfully distinct from *O. s. malayanus* [of Malay Peninsula] — Peters. More specimens are needed to settle the status of the Andaman population.

GENERAL HABITS, FOOD, VOICE and CALLS. Nothing specifically recorded.

BREEDING. Not described.

MUSEUM DIAGNOSIS. Differs from other races in having the 4th primary (as.) longest or subequal to 3rd; first primary between 8th and 9th. Above, cinnamon-brown, only faintly spotted and vermiculated. Scapulars with pure white markings on outer edges. Below, throat and chest greyer than in other races. Belly with considerable white, closest to *sunia* in this respect. Tarsus feathered for three-quarters its length.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
1 ♂	143	—	—	— mm.
4 ♀ ♀	140-142	16 (1)	22 (1)	62 (1) mm. (SDR)

COLOURS OF BARE PARTS. As in 616 and the other races.

618b. Nicobar Scops Owl. *Otus scops nicobaricus* (Hume)

See Appendix

OWLS

267

BREEDING. Season, chiefly April-May. Nest, a tree-hollow at moderate height. Eggs, 3 to 5, white, roundish, smooth-textured, as typical of owls. Hume's measurements for his eggs average c. 32.2 × 28.0 mm.; average size of 12 eggs from the Punjab Himalayas (Murree) and Kumaon (Simla and Naini Tal) 28.4 × 23.7 mm. (Baker).

MUSEUM DIAGNOSIS. For wing formula see under the Species (above). The only Indian race with feathering on toes extending to the subterminal phalanx. As large as the eastern *lettia* (624), but slightly darker brown and less rufescent above — though rather variable in this.

MEASUREMENTS

♂ ♀ Wing 162-182 mm. (47 measured) — Ticehurst. Bill (from feathers) 22-24 mm. — Baker.

COLOURS OF BARE PARTS. As in the nominate and other Indian races.

620. West Pakistan Collared Scops Owl. *Otus bakkamoena deserticolor* Ticehurst

Otus bakkamoena deserticolor Ticehurst, 1922, Bull. Brit. Orn. Cl. 42: 57
(Hyderabad, Hyderabad dist., Sind Province, India)
Baker, FBI No. 1670, Vol. 4: 426

LOCAL NAMES. None recorded.

SIZE. Myna ±; length c. 23-25 cm. (9-10 in.).

FIELD CHARACTERS. As of 619, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident; not uncommon. West Pakistan (Baluchistan and Sind). This is possibly also the form that occurs in N. Gujarat. Affects forest and the better wooded parts. Partial to topes of trees in gardens, e.g. of Inspection Bungalows, and on canal banks and roadsides.

Extralimital. There are specimens in the Bombay Natural History Society's collection labelled Bushire (Persian Gulf) and Muscat (southern Arabia). No other information.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 619, q.v. Seldom seen in daytime when it hides up in thickly foliated trees; its presence only betrayed at night by its distinctive soft monosyllabic *wüt* . . . *wüt* call.

BREEDING. Season, March-April. Nest (tree-hole) and eggs (3 or 4 white, spherical) as in 619. Size of eggs c. 33 × 27 mm.

MUSEUM DIAGNOSIS. For wing formula see under the Species (above). A very pale race; ground colour pale grey-brown; underparts almost white, with practically no rufescent tinge; yellow-buff on the collar and scapulars very pale. Tarsus feathered only to base of toes.

MEASUREMENTS

♂ ♀ Wing 165-175 mm. (Ticehurst). Bill (from feathers) 20-22 mm. (Baker).

COLOURS OF BARE PARTS. As in the nominate and other Indian races.

266

STRIGIFORMES

OTUS BAKKAMOENA Pennant

The species differs from *Otus scops* in wing formula: 1st primary (as.) much shorter than 8th and about equal to shortest secondary; 2nd primary between 6th and 7th or 7th and 8th; 4th or 5th primary longest. Also in the possession of a distinct pale collar on hindneck.

Cf. Ticehurst, C.B., 1923, *Ibis*: 238-40.

619. Punjab Collared Scops Owl. *Otus bakkamoena plumipes* (Hume)

Ephialtes plumipes Hume, 1870, *Ibis*, ser. 2, 6 (July): 439 (India = Murree, Punjab)
Baker, FBI No. 1669, Vol. 4: 425

LOCAL NAME. *Tharkari choghād* (Hindi).

SIZE. Myna ±; length c. 23-25 cm. (9-10 in.).

FIELD CHARACTERS. A delightful little 'horned' or 'eared' owl, very similar to Scops; differentiated from it chiefly by presence of a prominent pale collar at base of hindneck (upper back). Sexes alike.

Adult. Above, grey-brown or rufous-brown, mottled and vermiculated with whitish. Below, chin and throat white or buff, the latter barred and stippled with black. Rest of underparts white to rich buff streaked with black, and with fine wavy bars of reddish brown.

STATUS, DISTRIBUTION and HABITAT. Resident. Western Himalayas between c. 900 metres (perhaps lower) and at least 2200 m. alt., from Murree eastward through Jammu and Kashmir (?), Himachal Pradesh, Garhwal, and Kumaon. Affects forest — sal, oak, pine, and deodar — and well-wooded country in the neighbourhood of hill cultivation.

GENERAL HABITS. Nocturnal; seldom seen by day, its presence in a locality being detected only by its distinctive calls at night. Spends the daytime lurking in some dark corner in a densely foliated branch standing upright and motionless, effectively disguised as a snag.

FOOD. Beetles, grasshoppers, and other insects, lizards, mice, and small birds.

VOICE and CALLS. A single mellow interrogative note *wüt?* jerked out unhurriedly and monotonously every three seconds or so, commencing at dark and continuing intermittently throughout the night, in runs of 10 to 15 minutes' duration or longer. The calling is resumed after a short break from a changed position in a different tree suggesting that the bird may be hunting for food in the interval. It is to be heard all through the year.

LOCAL NAME. *Tharkari choghād* (Hindi).

SIZE. Myna ±; length c. 23-25 cm. (9-10 in.).

FIELD CHARACTERS. As of 619, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident. Mt Abu and eastern Rajasthan through Uttar Pradesh, approximately to Allahabad. Eastern Nepal terai (Fleming, JBNHS 65: 328) and possibly N. Bihar. Precise limits undefinable. Affects wooded country, mango orchards, and gardens with densely foliated trees.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 619, 620, q.v.

BREEDING. Season, March and April with perhaps an extra week or two at either end. Nest, a hole or hollow in a tree-trunk in mango orchards or groves around villages. Eggs, normally 3 or 4, occasionally 5, white, spherical, as in the other races. Average size of 50 eggs 33.1 × 28.1 mm. (Baker).

MUSEUM DIAGNOSIS. Wing formula as in the Key to the Species, q.v. Tarsus feathered only to base of toes. General coloration paler and more yellowish grey than in Madhya Pradesh birds (*marathas*) but this readily seen only in series; single specimens and borderline cases often impossible to place.

MEASUREMENTS

♂ ♀ Wing 153-167, mostly 155-162 mm. (19 measured) — Ticehurst.
Bill (from feathers) 19-21 mm. — Baker.
Weight 1 ♂ 121 gm. (SA).

COLOURS OF BARE PARTS. As in the other races.

622. Central Indian Collared Scops Owl. *Otus bakkamoena marathas* Ticehurst

Otus bakkamoena marathas Ticehurst, 1922, Bull. Brit. Orn. Cl. 42: 122
(Raipur, Central Provinces)
Baker, FBI No. 1667, Vol. 4: 424

LOCAL NAME. *Tharkari choghād* (Hindi).

SIZE. Myna ±; length c. 23-25 cm. (9-10 in.).

FIELD CHARACTERS. As of 619, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident. Approximately between lat. 20° and 24°N. from the Surat Dang (Gujarat) eastward through W. Bengal; precise limits not worked out. Affects forest, and groves & densely foliated trees in gardens, and about villages and cultivation.

GENERAL HABITS, FOOD, VOICE and CALLS. As in the other races, q.v.

BREEDING. Season, January to April. Nest and eggs as in 619, 620, q.v.

MUSEUM DIAGNOSIS. Wing formula as in the Key (p. 253). General coloration as in *plumipes*, and in a series darker than *gangeticus*. Size larger than nominate

OWLS

269

bakkamoena (623), smaller than *lettia* (524). Tarsus feathered only to base of toes as in 623.

MEASUREMENTS

♂ ♀ Wing 152-162, once 165, mm. (41 measured) — Ticehurst.

COLOURS OF BARE PARTS. As in the other races.

623. Ceylon Collared Scops Owl. *Otus bakkamoena bakkamoena* Pennant

Otus bakkamoena Pennant, 1769, Ind. Zool.: 3, pl. 3 (Ceylon)

Baker, FBI No. 1666, Vol. 4: 422

Plate 54, fig. 4

LOCAL NAMES. *Pedda chittā gūbā* (Telugu); *Pānchi bassā* (Sinhala); *Sīmā āndāi*, *Nethē* (Tamil, Malayalam).

SIZE. Myna ±; length c. 23-25 cm. (9-10 in.).

FIELD CHARACTERS. As of 619, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident; widespread but local. Peninsular India south of the range of *marathae* (i.e. from c. 20°N. lat.)—Maharashtra, Madhya Pradesh, Andhra, Tamil Nadu, Mysore, and Kerala; also Ceylon (all zones). Plains and hills to at least 1200 m. altitude. Affects deciduous and semi-evergreen forest, and well-wooded country; partial to groves and orchards around villages and cultivation.

GENERAL HABITS, FOOD. As in 619, q.v.

VOICE and CALLS. In addition to the regularly spaced interrogative *wūt... wūt* (or *what? ... what?*) calls (q.v. 619), has an occasional series of slowly repeated *ack, ack, ack*, etc. in ascending scale strung out for five seconds or so; usually interposed between the normal notes but sometimes heard independently. This peculiar bubbling or chattering is common to the other races as well.

BREEDING. Season in peninsular India principally January and February; in Ceylon March and April; occasionally July (Phillips). *Nest*, as in 619 and other races, an unlined hole or hollow in a tree-trunk or bough c. 2 to 7 metres up, in Kerala and Ceylon frequently on the edge of tea and rubber plantations. Exceptional nesting in roofs of houses and holes in walls recorded in Kerala. *Eggs*, 3 to 5, white, smooth-textured, almost spherical. Average size of 27 eggs 31.8 × 27.0 mm. (Baker). Share of the sexes in incubation and other domestic chores, and period of incubation, unrecorded.

MUSEUM DIAGNOSIS. Wing formula as for the Species: 1st primary (as.) much shorter than 8th; 4th or 5th primary longest. The smallest and darkest of the Indian races. Warmer, darker brown and yellower than *marathae* (622). Has also a rufous grey phase in both adults and young. Tarsus feathered only to base of toes.

Young (immature). Pale grey or pale to warm fulvous narrowly barred all over with dusky brown bars, these covering even face and chin (Baker).

× c. 4

OWLS

271

COLOURS OF BARE PARTS. Iris yellowish brown. Bill greenish horn, paler at base, blacker near tip; lower mandible pale dusky yellow. Feet and claws fleshy grey to dusky olive; pads yellowish white.

Genus *BUBO* Dumeril

Bubo Dumeril, 1806, Zool. Analytique: 34. Type, by tautonymy, *Strix bubo* Linnaeus.

Ketupa Lesson, 1830, Traité d'Orn., livr. 2: 114. Type, by tautonymy, *Ketupa jaceensis* Lesson = *Strix ketupu* Horsfield.

Hubua Hodgson, 1836, Asiat. Res. 19: 171-4. Type, by original designation, *Bubo nipalensis* Hodgson.

Includes Horned Owls, Eagle-Owls, and Fish Owls, large powerful birds with long, pointed 'horns' or ear-tufts (aigrettes). Ear orifice not exceeding eye in size; no operculum. Facial disc generally ill defined and never extending as far above eye as below it; ruff nearly or quite obsolete.

LOCAL NAMES. *Boom* (Baluchistan); *Oğ-pa* (Ladakh).

SIZE. Pariah Kite +; stouter. Length c. 66 cm. (26 in.).

FIELD CHARACTERS. As of 627, q.v. A large brown owl, streaked and mottled tawny buff and black, with two prominent upstanding black 'horns' or ear-tufts above the head. Sexes alike. See Museum Diagnosis.

270

STRIGIFORMES

MEASUREMENTS

♂ ♀ Wing 135-152, once 154, mm. (38 measured) — Ticehurst.

Bill (from feathers) c. 20-22; tarsus 30-32; tail 64-67 mm. (Baker).

COLOURS OF BARE PARTS. Iris yellow, golden yellow, hazel or brown (age?). Bill greenish horny brown, paler on lower mandible darker at tip; cere dusky green; mouth pink. Feet brownish flesh to greenish yellow; claws pale horny brown.

624. Burmese Collared Scops Owl. *Otus bakkamoena lettia* (Hodgson)

Scops lettia Hodgson, 1836, Asiat. Res. 19: 176 (Nepal)

Otus bakkamoena manipurensis Roonwal & Nath, 1949, Rec. Ind. Mus. 46: 162

(6 miles north of Imphal, Manipur)

Otus bakkamoena alboniger Kock, 1952, Jour. Zool. Soc. India 4: 45

(Hmüntha, Lushai Hills)

Baker, FBI No. 1671, Vol. 4: 427

LOCAL NAME. *Lātyā kūyāl* (Nepal).

SIZE. Myna ±; length c. 23-25 cm. (9-10 in.).

FIELD CHARACTERS. As of 619, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident, Eastern Himalayas from Nepal through Sikkim, Bhutan, and NEFA. Assam north and south of Brahmaputra river, Nagaland, Manipur, Mizo, and East Pakistan; from the plains and submontane tracts to c. 2400 metres. Affects forest—sal, oak, pine, deodar, etc.—around hill cultivation; also groves of trees and bamboos about habitations.

Extralimital. All Burma, northern Thailand.

GENERAL HABITS, FOOD. As in 619 and other races, qq.v.

VOICE and CALLS. In addition to the calls as under 619 and 623, SA records a short mellow single hoot, quite different from the normal *what?* or *wut?* and repeated at much longer intervals (15 to 20 seconds). A bird uttering this call when shot at 2.30 a.m. had its stomach crammed with a freshly ingested field mouse.

BREEDING. Season, February to April. *Nest*, a natural hollow or woodpecker hole in a tree-trunk or dead stump c. 2 to 5 metres up. *Eggs*, 3 or 4, rarely 5, white, roundish ovals as in the other races. Average size of 34 eggs 32.3 × 28.1 mm. (Baker). On circumstantial evidence both sexes share in incubation, but this needs proving. Period of incubation and other points of breeding biology unrecorded.

MUSEUM DIAGNOSIS. Wing formula as in the Species. Tarsus feathered only to base of toes. Larger than any of the Indian races except *plumipes* (619). Coloration as in nominate *bakkamoena* (623).

MEASUREMENTS

♂ ♀ Wing 162-182 mm. (40 measured) — Ticehurst.

Specimens recently collected in Nepal give:

	Wing	Bill	Tail
5 ♂♂	158-168	24-25	75-85 mm.
4 ♀♀	159-180	24-25	83-89 mm.
		(from skull)	(BB)

Weight 1 ♀ 170 gm. (BB).

272

STRIGIFORMES

General aspect in flight a stout yellowish tawny owl, heavily spotted and streaked with blackish, with broad rounded wings.

STATUS, DISTRIBUTION and HABITAT. Resident; sparsely scattered over extensive tracts of high mountain country chiefly between c. 1800 and 4500 metres: Gilgit, Chitral, Ladakh,¹ Kashmir. Affects open plateaux, steep mountainsides, bare rocky cliffs, and old ruined forts, etc.

Extralimital. 'Kazakhstan from the region between the lower Volga and the lower Ural rivers east across the southern Kirghiz Steppes to the regions of Semipalatinsk and Lake Balkhash, and south to Transcaspia and the basin of the Chu river...' (Vaurie, loc. cit.).

GENERAL HABITS. As in 627, q.v. but keeps to bare rocky hillsides.

FOOD. Largely rodents and game birds; hare (*Lepus*) and mouse-hare (*Ochotona*) among the former, and Snow Partridge (*Lerwa lerwa*), Ruddy Shelduck (*Tadorna ferruginea*) adults and ducklings, and Rock Pigeons (*Columba*) among the latter have been identified. Remains of fish (one of c. 1 + kg.) recorded from a nest with young.

VOICE and CALLS. Evidently as in 627.

BREEDING. Little recorded. Meinertzhagen found two nests (apparently disused ones of some diurnal raptor) in Ladakh¹ (Chimre c. 3600 m. and Shushal c. 4300 m. in May and June). *Nest* in both cases a pad of twigs c. 1 m. in diameter lined with smaller twigs, hare-fur and feathers (possibly left-overs from meals) and fine roots; one placed in a rock fissure, the other on a shelf with an overhanging ledge. *Eggs*, apparently only 2. Measurements not given, but the six large ones averaging 60.1 × 47.3 mm. taken by Osmaston in Kashmir (see under 627) presumably belong to this race.

MUSEUM DIAGNOSIS. A pale subspecies 'resembling *hemachalana* (626a) in general coloration, but duller, less variegated, and not so distinctly patterned'. Toes completely feathered, the feathers overhanging and concealing base of claws, *contra bengalensis* where last joint of toes naked.

MEASUREMENTS

Wing 12 ♂♂ 440-470 (av. 449.7); 21 ♀♀ 445-512 (482.4) mm. (Vaurie).

Bill (from feathers) 45-47; tarsus 77-81; tail 260-310 mm. (Baker).

COLOURS OF BARE PARTS. Iris golden yellow. Bill greenish black, slaty black to black. Toes dull greenish; claws greenish slate, darker at tips (Baker).

626. Tibetan Horned or Eagle-Owl. *Bubo bubo tibetanus* Bianchi

Bubo bubo tibetanus Bianchi, 1906, Bull. Brit. Orn. Cl. 16: 69

(Upper Yangtze River in southeastern Tibet)

Baker, FBI No. 1659, Vol. 4: 414

LOCAL NAMES. None recorded.

SIZE. Pariah Kite +; stouter. Length c. 66 cm. (26 in.).

FIELD CHARACTERS. As of 627, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Range within our limits hypothetical. According to Vaurie (1965: 587) 'probably also inhabits the eastern

¹ See footnote, p. 273.

Himalayas at high altitudes'. Thus may occur in northern Sikkim, and perhaps also N. Bhutan and NEFA, but no evidence of this as yet.¹

Extremities. Central and eastern Tibet (regions of Lhasa, Gyantse, and Khamba Dzong) eastward to central Kansu, and south to extreme NW. Yunnan (Vaurie).

GENERAL HABITS, FOOD, VOICE AND CALLS, BREEDING. Not recorded in Indian limits; presumably as in 625 and 627, q.v.

MUSEUM DIAGNOSIS. See Key to the Subspecies; also under 625 and 626a.

MEASUREMENTS

Wing 13 ♂♂ 450-485 (av. 461); 9 ♀♀ 490-505 (493.8) mm. (Vaurie).

COLOURS OF BARE PARTS. As in 625.

626a. Himalayan Horned or Eagle-Owl. *Bubo bubo himachalensis* Hume

B. (bubo) himachalensis A.O.H. (= Hume), 1873, *Stray Feathers* 1: 315

(Kulu, 12,000 feet, India)

Not in Baker, FBI

LOCAL NAME. *Borin* (Baluchistan).

SIZE. Pariah Kite \pm ; stouter. Length c. 66 cm. (26 in.).

FIELD CHARACTERS. As of 627, q.v. See *Museum Diagnosis*.

STATUS, DISTRIBUTION AND HABITAT. Northern Baluchistan (Kalat, Quetta) NW. Himalayas, Ladakh (see footnote under *tibetanus*), and Himachal Pradesh (Kulu, Lahul)—between c. 2000 and 4200 m. altitude. Status and range *vis-à-vis tibetanus* confusing.

Extremities. Western Tibet (perhaps Badakhshan in eastern Afghanistan), north to the western Kun Lun and the western Tian Shan in Chinese Turkistan (Vaurie).

GENERAL HABITS, FOOD, VOICE AND CALLS, BREEDING. See under *tibetanus* (625).

MUSEUM DIAGNOSIS. See Key to the Subspecies.

MEASUREMENTS

Wing 3 ♂♂ 450-472 (av. 462); 7 ♀♀ 470-505 (492.3) mm. (Vaurie).

COLOURS OF BARE PARTS. As in *tibetanus* (625).

627. Indian Great Horned or Eagle-Owl. *Bubo bubo bengalensis* (Franklin)

Otus Bengalensis Franklin, 1831 (1830-31), *Proc. Zool. Soc. London*: 115

(The Ganges between Calcutta and Benares and in the Vindhyan Hills

between the latter place and Gurra Mundela)

Baker, FBI No. 1660, Vol. 4: 414

Plate 53, fig. 1

LOCAL NAMES. *Ghaghā* (Hindi); *Gēg* (Sind); *Hāim pēhā* (Bengal); *Ghāhād* (Marathi); *Ghāhād* (Gujarati); *Terra gulla gulla* (Telugu); *Kemān āndai* (Tamil); *Kemān mēga* (Malayalam).

¹ Considerable uncertainty prevails in the records of the races of this variable owl along our northern borders due to the paucity of skins in collections and the fact that *bengalensis*, *himachalensis*, and *tibetanus* have been consistently confused. For example Meinertzhagen (*Ibis* 1927: 605) assigned his breeding birds from Ladakh to *tibetanus* (q.v.) whereas Vaurie, with the advantage of access to fuller material in Russian museums, states that all the specimens he has seen from Ladakh are *himachalensis*, into which 'tibetanus' probably grades in W. Tibet' (loc. cit.). The confusion is understandable since the differences between the populations are slight and only perceptible in a series which is not readily available to most workers.

BREEDING. Season, overall October/November to May, chiefly February to April, but peak periods vary locally. *Nest*, no structure; eggs laid on the bare soil in a saucer-like scrape, generally on a sheltered ledge of rock or in a recess in a clay-cliff flanking a ravine; sometimes on the ground under a bush or tree. Eggs, normally 4, sometimes only 2 or 3; white with a faint creamy tinge, broad roundish ovals, smooth-textured and often with a slight gloss. Average size of 40 eggs from Kashmir 58.1 × 46.0 mm. [of six 60.1 × 47.3 mm. (Osmaston)], of 100 from the Peninsula 53.6 × 43.8 mm. (Baker). Share of the sexes in incubation, and period, unrecorded. The considerable disparity in growth of young in the same brood suggests that eggs are laid at longer than 24-hour intervals and that incubation commences with the first egg. When a nest with chicks is approached the parents frequently resort to diversionary tactics, feigning wing injury 'by turning from side to side with their heads down and flapping their wings like a beheaded chicken, squealing at the same time' (Dharmakumarsinhji).

MUSEUM DIAGNOSIS. Tarsus fully feathered to toes. Feet exceptionally powerful; claws well curved, the inner or 2nd claw longest. Third primary (as-) longest, or 3rd and 4th subequal. Tail moderately long and slightly rounded. For details of plumage see Baker, loc. cit. This is a variable race with paler (more buff) and darker (more rufous) phases and a cline in size—largest in N. India, smaller in the south.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
7 ♂♂	364-390	42-47	69-76	185-195 mm.
3 ♀♀	375-425	44-46	70-75	205-227 mm. (SA, HW)

Wing 10 ♂♂ 358-391 (av. 370); 12 ♀♀ 376-403 (av. 387) mm.—Vaurie.

Weight 1 ♂ 1100 gm. (GD).

COLOURS OF BARE PARTS. Iris bright orange-yellow or reddish orange. Bill horny brown; mouth pink. Feet dirty greyish brown; claws horny black.

MISCELLANEOUS. In most parts of India the large owls are considered birds of ill omen, foreboding death to one of the inmates of a house on which one happens to settle at night and call. There is a great deal of folklore connected with these birds, and some fantastic beliefs and superstitions which command wide credulity. Here are two popular recipes:

1. Keep an owl without food for eight days. Thereafter beat it well with a stick when it will begin to talk fluently like a human (language unspecified!) and tell your fortune with infallible accuracy.

2. Keep an owl in a dark chamber; give it no food. Drive a nail in the centre of the room and tie the bird to this by one of its legs. Sit near the bird for an hour every day and chant the prescribed mantra (words not disclosed!). After 40 days put the dead bird in a sack and hang up from the ceiling of the room for a further 21 days. Thereafter separate the bones from the rest and go to the bank of a river where nobody must see you. Pick out the bones one by one and throw them in the water. The bone that swims like a snake, keep that; you will get your heart's desires for evermore!

BUBO NIPALENSIS Hodgson

Key to the Subspecies

A narrow pectoral band of brown with a golden tinge... *B. n. nipaleus*

No pectoral band as above... *B. n. blighi*

SIZE. Pariah Kite \pm ; stouter. Length c. 56 cm. (22 in.).

FIELD CHARACTERS. A large dark brown owl, streaked and mottled with tawny buff and black, with two prominent upstanding blackish 'horns' or ear-tufts (aigrettes) above the head, large round forwardly directed orange eyes, and fully feathered legs. Sexes alike.

'Large size and conspicuous ears make it look, when sitting motionless, more like a large cat than a bird' (Unwin, Kashmir).

On a good view may be distinguished from Brown Fish Owl by feathered r. naked legs, and more erect r. nearly horizontal 'horns'.

STATUS, DISTRIBUTION AND HABITAT. Resident in suitable biotopes throughout the subcontinent from c. 1500 m. (rarely c. 2400 m.) in the western Himalayas—Punjab (Kohat, Peshawar, Rawalpindi dists.), Kashmir, and eastward at least to west-central Nepal (possibly further east, but not yet recorded from Sikkim, Bhutan or NEFA). Sind, Rajasthan, and across the Gangetic Plain to Assam, Nagaland, Manipur, and East Pakistan; south throughout the Peninsula to Kanyakumari, plains and hills. Not in Ceylon, or Andaman and Nicobar Is. Affects bush-covered rocky hills and wooded country with outscoured ravines, and old mango orchards and groves of ancient trees in the neighbourhood of cultivation and villages; partial to steep earth banks and clay cliffs of dry nullahs and rivers. Not uncommon in eroded semi-desert thorn jungle, but avoids both pure desert tracts and humid evergreen forest.

Extremities. Arakan (Burma).

GENERAL HABITS. Largely nocturnal, but may frequently be seen perched on a pinnacle of rock or similar exposed situation well before sunset and till long after sunrise. Spends the daytime in the seclusion of a thickly foliated bough or in a fissure of rock, sheltered ledge on a clay-cliff flanking a ravine, or among ruined and deserted buildings. When flushed will fly considerable distances in open sunshine with no apparent discomfort, and has been observed pouncing on a bull frog in broad daylight (Magrath). Flies with slow deliberate flaps interspersed with long bouts of gliding on outstretched wings, usually fairly close to the ground. Refuge by day probably sought largely in order to escape the mobbing and chivvying which it invariably receives from all diurnal birds as soon as it shows itself. Issues forth at sundown heralded by a deep resounding double hoot.

FOOD. Predominantly field rats and mice. In the egg-shaped cast-up pellets freely littered below nests and daytime retreats, rodent fur, bones and skulls are almost invariably the chief component. Thus the bird is of major significance to agricultural economy. Also eats birds (remains of peafowl, partridge, and roller identified in stomach contents), reptiles, frogs, crabs, and large insects.

VOICE AND CALLS. A deep, resonant, hollow *hō-hō* (accent on second syllable which much prolonged) repeated at intervals; not particularly loud but with a curious penetrating and far-carrying quality. This call has also been rendered as a deep and solemn *hū-gūn* or *hū-tū-tū*. At nest, or when cornered, snaps mandibles loudly, producing a loud *tuck, tuck, tuck* (like the clicking of one's tongue against the palate), and hisses menacingly, fluffing its plumage and spreading out the wings at the sides.

628. Forest Eagle-Owl. *Bubo nipaleus nipaleus* Hodgson

Bubo nipaleus Hodgson, 1836, *Asiat. Res.* 19: 172 (Nepal)

Habua pectoralis Jerdon, 1840, *Madras Jour. Lit. Sci.* 10: 89 (Malabar)

Baker, FBI No. 1663, Vol. 4: 418

Plate 53, fig. 2

LOCAL NAMES. *Habū*, *Habū chel* (Nepal); *Migiri* (Bhutan); *Ureza*, *Kem mēga* (Malayalam); *Das ts gao chee* (Cachar).

SIZE. Pariah Kite \pm ; heavier built; length c. 63 cm. (25 in.).

FIELD CHARACTERS. A large, powerful, nocturnal brown owl with two outwardly slanting erect black-and-white 'horns' or ear-tufts above the head, fully feathered legs, and *brown* eyes (contra orange in Great Horned).

Adult. Above, dark brown scalloped with buff. Below, fulvous white, barred with blackish on throat and breast, the bars breaking up into chevron-like spots on abdomen. Sexes alike.

Young (immature) pale buff, whiter on head, barred above and below with dark brown. Tail and wings as in adult: dark brown with fulvous bars.

STATUS, DISTRIBUTION AND HABITAT. The submontane tracts and lower Himalayas up to c. 2100 m. (normally to c. 900-1200 m.) from Kumaon eastward through Nepal, Sikkim, Bhutan, and NEFA (?). Assam hills north and south of Brahmaputra river, Nagaland, Manipur, and East Pakistan. Peninsular India in the Western Ghats and associated hills from about Belgaum (c. 16°N. lat.) south through western Mysore and Kerala. Also Shevaroy Hills (southern Eastern Ghats). Affects dense evergreen and moist deciduous forest as in the tropical valleys, terai and duars in the north, and sholas in the southern hills.

Extremities. North and central Burma. Recorded also from Thailand, Laos and central Vietnam.

GENERAL HABITS. Largely nocturnal, spending the day dozing on some densely foliated bough in deep forest or shola; sometimes on the move and even hunting during daytime. At evening dusk moves up to the edge of clearings or streams in quest of prey, but is essentially a forest dweller and does most of its hunting within the forest. A bold and powerful owl, capable of overpowering such large birds as peafowl and junglefowl, pouncing on them while asleep at their nightly roosts in trees or bamboo clumps.

FOOD. Chiefly game birds like the above, and pheasants. Is reported to kill jackals, hare, and fawns of barking deer; also eats lizards, snakes and fish.

VOICE AND CALLS. 'A low, deep and far-sounding meaning hoot' (Jerdon). A long-drawn kite-like whistle, occasionally heard in forest at night, has circumstantially been attributed to this owl; likewise the diabolical blood-curdling shrieks as of a woman being strangled, which have suggested the name 'Devil Bird'. However, the true identity of the Devil Bird remains unproven.

BREEDING. Season, in the Himalayas February-March; in Kerala December-January. In N. Cachar Baker took an egg in June. *Nest*, a hollow in an ancient tree, or a deserted stick-nest of an eagle brought into commission. Sometimes the egg is laid on the bare soil in a cave or horizontal fissure in a rock scarp. Egg, a singleton, white, roundish oval with a smooth

OWLS

277

surface. Average size of 10 eggs 61.2 × 49.9 mm. (Baker). Share of the sexes in incubation, incubation period, and other facets of breeding biology unknown. Reported to be very fierce and aggressive in defence of its egg or nest-young.

MUSEUM DIAGNOSIS. For details of plumage, see Baker, loc. cit. Wing more rounded than in *Bubo bubo*: 4th and 5th primaries (as.) longest. Differs from that species also in the character of the juvenile plumage which is quite distinct from that of the adult.

Young (juvenile plumage). *Above*, including lesser and median coverts and tertiaries, white, washed with warm buff except on crown and hind nape; spotted or barred on the head, barred on the hindneck and rump, and crescent-barred with dark brown elsewhere. Face yellowish white. *Below*, white, washed with buff and barred with dark brown. Tail and wings as in adult: dark brown with fulvous bars (Whistler).

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	425-470	52-54	c. 60-62	229-250 mm. (Baker)

South Indian birds smaller than Himalayan.

COLOURS OF BARE PARTS. Iris brown or hazel brown. Bill dull wax-yellow to yellow. Toes dusky yellow; claws pale horny, darker at tips.

629. Ceylon Forest Eagle-Owl. *Bubo nipalensis blighi* Legge

Bubo blighi Legge, 1878, Bds. Ceylon, pt. 1: 133 (Kandy district, Ceylon)
Not in Baker, FBI.

LOCAL NAMES. *Lotū baharūnā* (Sinhala); *Periya āndai* (Tamil).

SIZE. Pariah Kite ±, heavier built; length c. 63 cm. (25 in.).

FIELD CHARACTERS. As of 628, q.v. A large powerful owl, brown above, brown-barred whitish below, with two long ear-tufts, feathered legs, and brown eyes.

STATUS, DISTRIBUTION AND HABITAT. Race peculiar to Ceylon. Resident; 'Widely scattered, in very small numbers, throughout the larger forest tracts both in the lowlands and in the hills to over 6000 feet [c. 1800 m.]' — Phillips.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 628, q.v. Normal call 'a deep, deep mumble or human-sounding snore' (Phillips).

Identified as probably the authentic Devil Bird. Henry (1955: 197) believes that the dreadful shrieks and strangulating noises are merely its 'mating love-song', which would also account for their rare and periodic occurrence.

BREEDING. *Season*, April-May. *Nest*. The only authentic one described was a collection of debris in the hollow formed by the junction of large boughs, c. 6 metres up, in a big tree by a stream in heavy forest at c. 600 m. alt. (Phillips). It contained a single half-grown young bird on 29 May. Egg, undescribed; presumably as in 628.

OWLS

279

VOICE AND CALLS. A deep, resonant, hollow *WOO, WOO, woo, woo-o-o-o-o* reminiscent of a large pingpong ball dropped from a height and allowed to bounce itself to silence, the sounds getting fainter and quicker with each successive bounce. Uttered both day and night, the birds being most noisy during the rainy and cold seasons. A loud snapping *tuck-tuck* of the mandibles when annoyed.

BREEDING. *Season*, overall November to April; principally December-January in N. India; somewhat later in the south. *Nest*, of sticks, in the fork of the trunk or boughs of some large peepul (*Ficus*), kadam (*Stephogyne*), sheesham (*Dalbergia*) or similar tree, preferably standing in or near water, and not infrequently close to habitation. Old nests of kites, vultures, and eagles are often appropriated, sometimes lined with a few green leaves. Eggs, normally 2 — sometimes only a singleton — white, roundish oval, typical of owls' eggs. Average size of 40 eggs 59.3 × 48.2 mm. (Baker). Eggs evidently laid at intervals of several days, thus resulting in great disparity in the size of the two chicks in a nest and in only the larger and stronger one usually reaching maturity. Share of the sexes in incubation, incubation period, and other details of breeding biology unknown.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

Chick (in down). When first hatched almost entirely covered with short pure white down. No tracts (Tiechurst).

Fledgeling. 'Overall rufous, with head and neck of a dirty grey colour, the whole plumage having a mealy appearance due to the longer down tips.'

'Lores clothed with a mixture of bristles and blackish sheath-encased feathers. Whole head and neck, excepting rufous ear-coverts, clothed with earthy coloured down with darker bases and greyish white tips, the whole having a somewhat barred appearance; this more pronounced on the head where the down is shorter. Whole body covered with *creamy rufous* down with a few dark shafts, the down of the legs somewhat lighter and ceasing at the toes which are sparsely covered with sprouting feathers tipped with down. The scapulars and wings bear feathers of the same tint, dark shafted, and vermiculated with dark brown. The quills are as yet confined in dark bluish cases, and only visible when the wing is lifted. The tail is merely represented by a tuft of down.'

'Iris bright yellow, pupil blue-black. Bill and cere bluish lead. Feet plumbeous, the soles lighter and the claws darker' (Whistler MS.).

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	380-415	41-43	65-70	205-210 mm. (Baker)
4 specimens from Gujarat give		(from skull)		
2 ♂♂	390-402	42-43	60-61	195-208 mm.
2 ♀♀	403-412	46-49	55-67	198-210 mm.
and a recent breeding ♀ from Rajasthan:	435	47	71	224 mm. (SA)

COLOURS OF BARE PARTS. Iris bright yellow. Bill bluish ivory. Toes (unfeathered tips) pale brown; claws blackish brown.

278

STRIGIFORMES

MUSEUM DIAGNOSIS. Smaller than the Indian race; slightly darker above, and with narrower and fewer bars on the underparts. But the population doubtfully distinct from South Indian.

MEASUREMENTS

	Wing	Bill (from skull)	Tail
3 ♂ ♀ (in B.M.)	370 (damaged) - 412	50.5-55.5	184-215 mm. (HW)

COLOURS OF BARE PARTS. As in 628.

630. Dusky Horned Owl. *Bubo coromandus coromandus* (Latham)

Strix coromanda Latham, 1790, Index Orn. 1: 53 (Coromandel Coast)
Baker, FBI No. 1661, Vol. 4: 416
Plate 53, fig. 3

LOCAL NAMES. *Gūg* (Sind); *Jūngli ghūghū* (Lucknow, U.P.); *Rādīyo ghūrd* (Gujarat).

SIZE. Pariah Kite ±; heavier built. Length c. 58 cm. (23 in.).

FIELD CHARACTERS. A large horned owl, similar to 627 but more grey or sooty-washed rather than tawny, and with paler yellow eyes (*contra* deep orange-yellow). When perched, the horns stand erect close to each other like twin spires. Sexes alike.

Adult. Overall, including ear-tufts, greyish brown finely mottled and vermiculated with whitish, especially on underparts, with dark shaft-strips to the feathers. A few buff and white spots about the shoulders. Wing- and tail-feathers brown with pale cross-bands and tips.

STATUS, DISTRIBUTION AND HABITAT. Resident; widely distributed in well-wooded, well-watered tracts throughout the subcontinent south of the Himalayas: Sind, Rajasthan, Punjab, Uttar Pradesh east through the terai and duars of Nepal, Sikkim (?), and Bhutan (?) to Assam south of Brahmaputra river, Manipur, and East Pakistan. South through the entire Peninsula to Mysore and the Nilgiris; no record further south. Affects old mango topos, and groves and roadside avenues of ancient tamarind and other densely foliated trees, in the neighbourhood of water and habitations — normally in the plains.

GENERAL HABITS. Usually keeps in pairs. Very parochial, pairs often inhabiting the same grove year after year. By no means entirely nocturnal, though usually spends the daytime in the seclusion of some shady bough, issuing forth an hour or so before sunset. Not particularly handicapped by daylight, may frequently be heard calling at all hours of the day, and seen on the move, even hunting, especially in cloudy drizzling weather.

FOOD. Small mammals, birds, reptiles, large insects, and doubtless frogs and fish. Among items identified in stomachs and from remains of food brought for nest-young, are hare, rats, striped squirrels, coots, pond herons, redwattled lapwings, once a shikra, rollers, ring doves, parakeets, house and jungle crows (very popular!). Also water beetles (*Dytiscus* sp.). The larger victims are evidently decapitated at site of capture as their heads are never found in the pellets, and only exceptionally (of smaller prey) with the headless bodies in the eyrie.

280

STRIGIFORMES

BUBO ZEYLONENSIS (Gmelin)

Key to the Subspecies

Smaller and darker; wing c. 355-385 mm. *B. z. zeylonensis*
Larger and paler; wing c. 375-445 mm. *B. z. leschenaulti*

631. Brown Fish Owl. *Bubo zeylonensis leschenaulti* (Temminck)

Strix leschenaulti Temminck, 1820, Pl. col., livr. 4, pl. 20
(Eastern provinces of India = Chandernagore)
Strix hardwickii Griffith, 1829, Anim. Kingd., Aves, 1: 77, ex Gray MS. (Futtegghur)
Baker, FBI Nos. 1653, 1654, Vol. 4: 408, 409
Plate 53, fig. 8

LOCAL NAMES. *Amrāi kī ghūghū*, *Ūllā* (Hindi); *Bhoatom pechā* (in imitation of its call. Bengal and East Pakistan); *Heedoo* (Assam); *Māchhimār ghūrd* (Gujarat); *Oomān* (Malayalam).

SIZE. Pariah Kite ±; stouter. Length c. 56 cm. (22 in.).

FIELD CHARACTERS. A large rufous-brown 'cared' owl, heavily streaked above with black. *Below*, whitish (pale fulvous) with fine wavy brown cross-bars and bold blackish streaks. A prominent large white patch on throat and foreneck. Eyes bright golden yellow. Legs naked (*contra* Eagle-Owl 627). Sexes alike.

Young (immature). *Above*, more rufescent with narrower and browner shaft-streaks. *Below*, paler and duller, with the shaft-streaks narrower, and merely a trace of the white throat-patch.

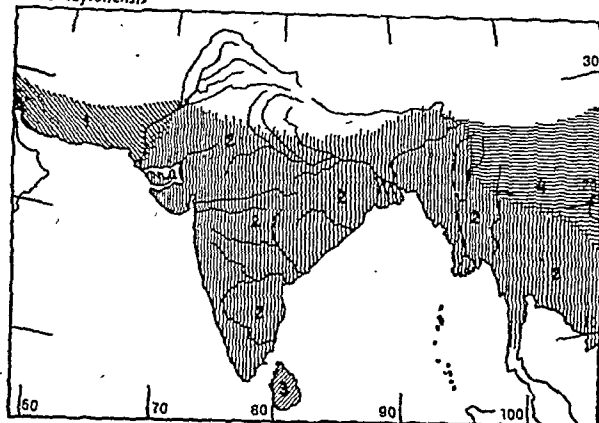

'Birds in the second year are duller and paler than birds in their third year' (Baker).

STATUS, DISTRIBUTION AND HABITAT. Resident. Submontane Himalayas (terai, bhabar, duns and duars) locally to c. 1500 m. alt. including Nepal, Sikkim, and Bhutan; the entire Indian Union and both Pakistans from Punjab (Kohat and Sialkot dists.), Jammu, western U.P., Rajasthan and Sind, eastward through the Gangetic Plain, Bengal, and Assam south of Brahmaputra river, Manipur and Eastern Pakistan (Dacca etc.). South throughout the Peninsula; chiefly plains, but locally up to c. 1400 m., e.g. in sholas in the Nilgiri, Palni and other hills. Affects well-wooded well-watered country; partial to old mango topos, roadside and canal avenues and densely foliated trees along forest streams and tanks; commonly near human habitations. Overgrown eroded ravines and steep riverbanks are favourite haunts.

GENERAL HABITS. Similar to the Dusky Horned Owl (630) both in partiality for the neighbourhood of water and its semi-diurnal habits. Keeps in pairs, usually roosting on some sheltered bough in a leafy tree, bamboo clump, or in an overgrown ravine, but frequently seen abroad in daylight and even hunting, especially in cloudy weather. Issues from its diurnal retreat well before sunset, announced by its deep booming calls. The bird takes up a position on a stump overlooking a pool, or on a rock in the middle or on the edge of a stream to keep a look-out for prey, often flying up and down in the quest, at times almost skimming the water. Fish are scooped up from near the surface, not caught by plunging like the Osprey.

OWLS

281

Bubo zeylonensis

Distributional range 1 *B. z. semenowi* (RE), 2 *B. z. lichenaulti* (631), 3 *B. z. zeylonensis* (632), 4 *B. z. orientalis* (RE).

It is fond of bathing and will waddle into the shallows at the edge, shuffling itself in the normal manner of birds, thereafter drying and carefully preening the plumage.

× c. 1

FOOD. Mainly fish, frogs, and crabs; also rodents, birds and reptiles (once a *Varanus* 28+ cm.). Has been observed feeding on the putrefying carcass of a crocodile.

VOICE AND CALLS. A deep, hollow-sounding boom-boom or boom-a-boom with a peculiar reverberating ventriloquistic quality, repeated at intervals. Suddenly 'exploding' in the stillness of the forest, the call has a distinctly eerie effect.

BREEDING. Season overall November to March; chiefly January–February in N. India, December to March in the Peninsula. Nest a cradle in the fork of the trunk or boughs of an ancient tree such as mango or *Ficus*, on a ledge or in a cleft in a rocky bank, or in an old derelict mausoleum or similar ruin; sometimes lined with a few twigs. Height above ground moderate and variable, but never far from water. Occasionally an old eagle's nest is appropriated. The same site is occupied year after year. Vicinity of nest always littered with cast-up food pellets and remains of its various victims.

Eggs, 1 or 2, white, roundish, with a smooth surface. Average size of 10 eggs 58.4 × 48.9 mm. Eggs of northern birds may be slightly larger (Baker).

OWLS

283

633. Tawny Fish Owl. *Bubo flavipes* (Hodgson)

Caltrunguis Flavipes Hodgson, 1836, Jour. Asiat. Soc. Bengal 5: 364, pl. 26 (Nepal) Baker, FBI No. 1657, Vol. 4: 411

Plate 53, fig. 11

LOCAL NAMES. Lak kyo-o ming ('the kyo-o calling devil' — Lepcha); Dao hao ho ho, Dao bu gao (Cachar).

SIZE. Pariah Kite ±; stouter. Length c. 61 cm. (24 in.).

FIELD CHARACTERS. As of 631, but above rich orange-rufous or tawny with broad blackish shaft-stripes. Much buff on scapulars and wing-coverts. Wing- and tail-quills dark brown, with buff bars and tips. Below, rich orange-rufous with dark brown shaft-stripes, broadest on breast; usually a white throat-patch. Sexes alike. For young (immature) see Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. The outer Himalayas (up to c. 1500 m.) from Kashmir (?) eastward through Himachal Pradesh, Garhwal, Kumaon, Nepal, Sikkim, Bhutan and NEFA (?). Assam hills north and south of Brahmaputra river, Nagaland, Manipur, Mizo, and East Pakistan (hill tracts). Affects forested banks of hill streams.

Extralimital. W. China, N. Burma; lower Yangtze Valley; Formosa; Indochinese countries — Peters.

GENERAL HABITS. Similar to Brown Fish Owl. Crepuscular and partially diurnal; often on the move and even hunting during daylight apparently with no discomfort. Perches on high trees overlooking water and swoops down to capture prey from near the surface in the manner of the fish eagles.

FOOD. Chiefly fish, crabs, lizards and large insects. Also rodents ('once remains of a small porcupine about a nest' — Baker) and game birds as large as junglefowl and pheasants.

VOICE AND CALLS. Seldom recorded. A deep whoo-hoo; as also in *B. zeylonensis*, has a curious mewling call, very like that of a cat — Baker.

BREEDING. Little known. Season (in Assam) December, January, and February. Nest, sometimes eggs laid in a hollow in a ravine- or river bank, but mostly (in Cachar, vide Baker) in old dilapidated nests of fish eagles, quite high up in trees, with no attempt to repair them. Eggs, normally 2, sometimes only a singleton, white, roundish ovals, very similar to those of 631. Average size of 10 eggs 57.1 × 46.9 mm. (Baker). Share of the sexes in incubation, and incubation period, imperfectly known. The birds, female in particular, said to be very bold and truculent in defence of the nest.

MUSEUM DIAGNOSIS. Tarsi feathered for about one-third of their length behind, and for about two-thirds in front and at the sides. For details of plumage see Baker, loc. cit.

Young (immature). A ♂ and a ♀ taken in Nepal, described as follows: 'Compared with adult birds, the juv. ♀ (18 May) has the upper plumage with distinct spots, and narrower and browner streaks; its under plumage is downy, chin white, and the streaks finer and paler; and its tarsi are covered with down up to about 24 mm. above the base of the middle toe. The juv. ♂ (June 2) is very similar to it, but without spots on the upper plumage' (Biswas).

MEASUREMENTS			
Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀ 410-455	c. 48-50	60-67	215-227 mm. (Baker)

282

STRIGIFORMES

Share of the sexes in incubation uncertain; incubation period 'approximately 5 weeks' (Baker).

MUSEUM DIAGNOSIS. Aigrettes long and pointed; facial disc ill-defined, especially above. Tarsus naked behind and usually more than half way up in front; naked portion granular, much as in Osprey; likewise soles of feet covered with prickly scales. Claws large, well curved, each with a sharp cutting edge beneath; middle claw with also a sharp keel on the side. Wings rounded, not reaching end of tail; 4th primary (as.) generally longest, 3rd and 5th subequal. Tail moderate. For details of plumage see Baker, loc. cit.

MEASUREMENTS			
	Wing	Bill (from skull)	Tarsus
6 ♂ ♂	379-443	49-54	71-90
7 ♀ ♀	392-430	50-54	71-86 (4 mud.)
			186-210 mm. 190-207 mm.

Weight 1 ♀ 1105 gm. (GD).

(SA, HW, BB)

Northern birds are larger than southern peninsular ones.

COLOURS OF BARE PARTS. Iris golden yellow. Bill pale greenish grey, dusky on culmen and tip. Legs and feet dusky yellow; claws horny brown.

632. Ceylon Brown Fish Owl. *Bubo zeylonensis zeylonensis* (Gmelin)

Strix zeylonensis Gmelin, 1788, Syst. Nat. 1(1): 287 (Ceylon) Baker, FBI No. 1652, Vol. 4: 406

LOCAL NAMES. Bakamuna (Sinhala); Periya andai, Umdain andai (Tamil).

SIZE. Pariah Kite ±; stouter. Length c. 56 cm. (22 in.).

FIELD CHARACTERS. As for 631; q.v. Ear-tufts shorter than in Eagle Owl (629); irides yellow v. brown; legs unfeathered. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Race peculiar to Ceylon; the commonest owl on the island. Resident and plentiful throughout the lowlands, and occurs in the hills to over 6000 feet [c. 1800 m.] — Phillips. Affects forest and groves of trees near water — tanks, and streams with rock pools.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 631. Henry describes the calls as 'doleful, and almost human-sounding moans, oomp-ooo-oo answered by its mate with an assenting oo'.

BREEDING. Season chiefly January to May; occasionally July. Nest and eggs as in the Indian race (631). Average size of 8 eggs 58.7 × 48.0 mm. (Baker).

MUSEUM DIAGNOSIS. Differs from the peninsular Indian population in its darker coloration and smaller size.

MEASUREMENTS

♂ ♀ Wing 365-383 mm. (as compared with *leschenaulti* from South India ♂ ♂ 379-405, ♀ ♀ 392-417 mm.) — Whistler.

COLOURS OF BARE PARTS. As in 631.

284

STRIGIFORMES

COLOURS OF BARE PARTS. Iris yellow. Bill horny black, sometimes yellowish at extreme tip; cere dingy green. Legs and feet yellowish grey, dingy greenish or slaty green; claws horny black.

Genus NYCTEA Stephens

Nyctea Stephens, 1826 (1825), in Shaw's Gen. Zool. 13 (2): 62. Type, by tautonymy and monotypy, *Strix erminia* Shaw = *Strix nyctea* Linnaeus = *Strix scandiaca* Linnaeus. Aigrettes very small, hardly visible; feathers of face and legs extremely long and hairy, almost concealing the bill and toes. Under tail-coverts very long, reaching almost to end of tail; otherwise wings and tail as in *Bubo*.

Contains a single Holarctic breeding species, accidental to our area.

634. Snowy Owl. *Nyctea scandiaca* (Linnaeus)

Strix scandiaca Linnaeus, 1758, Syst. Nat., ed. 10, 1: 92 ('Habitat in Alpihus Lapponiae' ex Fn. Suec., Aves, no. 46, there based on a drawing by Rudebeck) Baker, FBI No. 1665, Vol. 4: 420

LOCAL NAMES. None recorded.

SIZE. Pariah Kite ±; stouter. Length c. 61 cm. (24 in.).

FIELD CHARACTERS. A large pure white round-headed owl, more or less flecked and barred with sepia brown, with densely feathered legs. Unique and unmistakable. Sexes alike, but female considerably larger.

STATUS, DISTRIBUTION AND HABITAT. A specimen once taken (March 3, c. 1876) at Mardan in W. Pakistan (c. 34°14'N., 72°5'E.) and several other examples claimed to be seen by shikari at the same time. Evidently an accidental waif during an 'exodus year' when the species, presumably owing to food-scarcity cycles, intrudes enormous distances south of its normal range. No subsequent record.

Extralimital. Breeds in the northern parts of the Holarctic region. In Eurasia, migrates south in winter to central Europe and central Asia.

GENERAL HABITS. A powerful diurnal owl with buzzard-like flight, sometimes chasing birds and striking them down in the air like a falcon. Lives largely on rodents and other small mammals.

MUSEUM DIAGNOSIS. For bionomics, structure, plumages, and other details see Witherby, 1938, 2: 309-12.

MEASUREMENTS			
	Wing	Bill (from base of feathers)	Tarsus
♂ ♂	398-415	30-38	55-65
♀ ♀	425-460	—	—
			195-225 mm. (Witherby)

COLOURS OF BARE PARTS. Iris golden. Bill and claws blackish horn.

Genus GLAUCIDIUM Boie

Glaucidium Boie, 1826, Isis von Oken, Bd. 2, col. 970. Type, by subsequent designation, *Strix passerina* Linnaeus (Gray, 1840, List Gen. Bds.: 6) Cf. Ripley, S. D., 1948, *Zoologica* 33: 193-202

No ear-tufts or aigrettes. Differs from *Athene* (q.v.) in having the upper plumage barred instead of spotted. Cere swollen; nostrils tubular. Tarsus feathered; toes

OWLS

285

covered above with bristles. Wing more rounded than in *Athene*: 1st primary (as.) very short; 3rd, 4th or 5th quill longest or the three subequal.

Genus represented throughout the Old World, and also in C. and S. America.

Key to the Species

	Page
A A distinct collar; wing under 105 mm.....	<i>G. brodiei</i> 285
B No collar; wing over 110 mm.....	1

Glaucidium brodiei garoense Koelz, 1952, Jour. Zool. Soc. India 4: 45 (Tura)

Baker, FBI No. 1696, Vol. 4: 450

Plate 54, fig. 7

LOCAL NAME. *Dao whit-tshit* (Cachar).

SIZE. Quail \pm ; length c. 17 cm. (6½ in.).

FIELD CHARACTERS. A charming diminutive owl, a passable miniature of the better known Barred Owllet (639). Overall, barred grey-brown with a prominent white supercilium, rufous half-collar on upper back, and white patch on throat. Also has a dimorphic rufous or chestnut phase. Sexes alike.

From behind, the hind collar together with a black spot on each side of nape look deceptively like a staring owl's face!

STATUS, DISTRIBUTION and HABITAT. The Himalayas from Chitral through Punjab, Kashmir, Himachal Pradesh, Garhwal, Kumaon, Nepal, Sikkim, Bhutan, and NEFA. Assam hills south of Brahmaputra river, Nagaland, Manipur, Mizo, East Pakistan hill tracts (?). From the submontane terai and duars up to c. 3200 metres altitude. Affects open hill forest of oak, rhododendron, fir, deodar, etc.

Extralimital. Extends to S. China (north to Anwei), south to the Malay Peninsula and northern Vietnam; Hainan I. (Peters).

GENERAL HABITS. A very diurnal little owl, usually seen singly perched close to the trunk on some thinly foliated branch in a tall forest tree. Flies about freely in open sunshine, even hunting and calling persistently at midday. Is also crepuscular, but far less nocturnal than many other owls. Flight, a series of rapid wing-beats punctuated by pauses. Suffers ceaseless mobbing and chivvying from small birds during daytime, whence it has been pertinently suggested that the peculiar staring face-like markings on the hindhead may be of value in discouraging attacks from the rear. So great is the animosity for it among tits and other birds that a mixed rabble can often be decoyed by imitating its calls. Extremely bold and fierce for its size, sometimes pouncing on birds almost as large as itself, and carrying them off to a perch in its talons. The victim is pinned under foot and torn up and devoured with vicious upward pulls of the bill.

OWLS

287

Pradesh (Dalhousie, c. 76°E.) eastward through Garhwal, Kumaon, Nepal and Sikkim to Bhutan. South throughout the Peninsula in appropriate biotopes (locally up to c. 2000 m. in the Nilgiris etc.), roughly east and south of a line from Almora (Kumaon) to Baroda (Gujarat), with a western extension to the Aravalli Range (Mt Abu area). Replaced in the Malabar coastal strip from c. 16°N. (S. Konkan) southward through Kerala by the race *malabaricum*, q.v.; resident in Ceylon — in the low-country Dry zone and Hill zone to c. 1100 m. Occurrence in Assam doubtful. Baker recorded it as 'occurring in small numbers everywhere' in N. Cachar (1897, JBNHS 11: 230), but omits it both from the *Fauna* and *Nidification*. Affects mixed moist-deciduous forest and secondary jungle; in the Peninsula, especially partial to the teak-and-bamboo facies in foothills country.

GENERAL HABITS. Keeps singly or in pairs. Largely crepuscular; most active an hour or so before dusk and likewise till after sunrise; but is also on the move during the night, and flies about freely — and even hunts — in daytime, especially in cloudy, drizzling weather. Normally retires during the day to some leafy branch or a tree hollow, perhaps more in order to escape the chivvying it invariably receives from small diurnal birds than from any handicap due to sunshine. Gives itself away by fussily dashing out from its retreat on the approach of a human, with rapid wing-flaps punctuated by pauses; settles in another tree a short way off, sitting upright and motionless with its head screwed round to stare at the intruder, looking deceptively like the snag of a dead branch. Over most of its range almost invariably found in the same facies and in loose association with tree pies (*Dendrocitta vagabunda*) and racket-tailed drongos (*Dicrurus paradiseus*).

FOOD. Locusts, grasshoppers, cicadas and other large insects; molluscs, lizards, small birds, mice.

VOICE and CALLS. Pleasant, distinctive, rather like distant crow of Red Junglecock to the uninitiated. Begins with a loud and slow *kāo* repeated 2 or 3 times, followed by *kāo-kūk* (or *kookūk*), *kāo-kūk*, *kāo-kūk*, *kāo-kūk* etc. of about five seconds' duration, quickening in tempo and fading off at the end. The head is slightly lowered while calling, giving the bird a hunchback profile, and the tail is wagged laterally or swung from side to side. Nuptial (?) song: a soft, musical, rather ventriloquistic, *cū-cū-cū-cū-cū* (4½ times), fading towards end. Uttered (in moonlight only?) monotonously for 15-4 minutes, with short pauses. Also has an occasional pleasant bubbling continuous *woioioioioioi*... *kek*, the final *kek* in a much higher key. Significance of this call not understood.

BREEDING. Season, March to May; in Ceylon unknown. Nest, a natural tree hollow, or deserted woodpecker or barbet's nest-hole in the trunk or branch of a tree standing in open forest, between 3 and 8 metres from the ground. Eggs, 3 or 4, white, roundish, typical. Average size of 28 eggs 31.5 × 26.8 mm. (Baker). Share of the sexes in incubation, and incubation period, unknown.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit. Some examples are much greyer than others, more particularly on lower back and tail. This apparently unconnected with provenance but in the nature of individual variation, presumably representing the grey phase found in most owls.

286

STRIGIFORMES

FOOD. Small birds, mice, lizards, cicadas, grasshoppers, beetles, and other large insects.

VOICE and CALLS. A pleasant 4-noted bell-like whistle *toot . . . tootoot . . . toot* uttered in runs of 3 or 4, repeated at intervals. The call often ends incompletely with only the *tootoot*. The calling bird bobs its head from side to side, producing a marked ventriloquial effect.

BREEDING. Season, March to June, mainly April-May. Nest, an unlined natural hollow, sometimes a very large one, or an old or forcibly appropriated barbet- or woodpecker hole, 2 to 10 metres up in a tree-trunk standing in fairly open oak or other hill forest. Eggs, normally 4, sometimes 3 or 5, white, roundish, typical of owls' eggs. Size c. 29 × 24 mm. Share of the sexes in incubation uncertain; incubation period undetermined.

MUSEUM DIAGNOSIS. In fresh plumage the white throat, white portions of underparts, and underwing, are strongly suffused with primrose yellow. For notes on the species, and break-up of over 100 skins in the Brit. Mus. collection into 6 colour groups irrespective of provenance, see Kinnear, *Ibis* 1937: 490-1.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂ ♀	88-101	14-15	21-23	57-66 mm.
		(from skull)		(SA, BB, Baker)

Weight 2 ♂♂ 52, 53, 1 ♀ 63 gm. (SA, SDR).

COLOURS OF BARE PARTS. Iris bright lemon-yellow. Bill greenish yellow; cere and gape bluish. Legs and feet pale greenish yellow to olive-grey; claws dark horny.

LOCAL NAMES. *Jāngli choghād* (Hindi); *Kālā khūsāt* (U.P.); *Chhōtā kālpēcha* (Bengal); *Pānchi bassā* (Sinhala); *Sinna āndai* (Tamil); *Adāci pēgēdigāntē* (Telugu).

SIZE. Myna \pm ; length c. 20 cm. (8 in.).

FIELD CHARACTERS. A small squat, round-headed owl without ear-tufts. Above, dark brown conspicuously barred with pale rufous. Below, chin, moustachial streak, middle of breast, and abdomen white; rest of underparts barred dark olive-brown and white or rufous-white. Sexes alike.

A fulvous or rufous patch on underwing conspicuous in flight. Call diagnostic, q.v.

STATUS, DISTRIBUTION and HABITAT. The submontane Himalayas (terai, bhabar, duns and duars), locally up to c. 2000 m. in the hills, from Himachal

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
		(from skull)		
17 ♂♂	124-134	18-21	22-28	66-80 mm.
22 ♀♀	126-136	17-21	22-29	63-84 mm.
				(SA, HW, BB)

Weight 2 ♂♂ 114, 114 gm. (GD).

COLOURS OF BARE PARTS. Iris bright lemon-yellow. Bill plumbeous to greenish yellow. Feet dirty greenish lemon-yellow; claws horny brown.

637. Malabar Barred Jungle Owllet. *Glaucidium radiatum malabaricum* (Blyth)

Athene malabaricus Blyth, 1846, Jour. Asiat. Soc. Bengal 15: 280

(Malabar Coast and Travancore)

Baker, FBI No. 1695, Vol. 4: 449

LOCAL NAMES. *Pānchi bassā* (Sinhala); *Sinna āndai* (Tamil); *Chembān nāthē* (Malayalam).

SIZE. Myna \pm ; length c. 20 cm. (8 in.).

FIELD CHARACTERS. A small, squat, round-headed barred owl without ear-tufts, very like 636 q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident; Malabar coastal strip from southern Konkan (c. 16°N.) southward through Goa, W. Mysore and Kerala. Moist deciduous biotope; chiefly low-country and foothills — locally to c. 1500 m. altitude. Affects mixed teak-and-bamboo and similar open forest.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 636, q.v.

BREEDING. Season, March to May. Nest and eggs as in the nominate race but 3 rather than 4 eggs reported to form the normal clutch. Average size of 30 eggs 30.4 × 26.4 mm. (Baker).

MUSEUM DIAGNOSIS. Differs from nominate *radiatum* (636) in being much darker and more rufous — practically bright chestnut in some specimens — especially on the upperparts, wings, breast and flanks.

MEASUREMENTS

COLOURS OF BARE PARTS. As in 636.

638. Chestnutbacked Barred Owllet. *Glaucidium radiatum castanonotum* (Blyth)

Athene castanonota Blyth, 1852, Cat. Bds. Mus. Asiat. Soc. 1: 39 (Ceylon)

Baker, FBI No. 1693, Vol. 4: 447

Plate 54, fig. 5

LOCAL NAMES. *Pānchi bassā* (Sinhala); *Sinna āndai* (Tamil).

SIZE. Myna —; length c. 19 cm. (7½ in.).

OWLS

289

FIELD CHARACTERS. As of 636, q.v., also without ear-tufts, but upperparts chestnut, narrowly cross-banded with blackish. *Below*, white, longitudinally streaked with olive-brown on abdomen instead of barred. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Resident; race peculiar to Ceylon. Widely distributed in small numbers throughout the dense forests of the Wet zone and western aspects of the hills to 6300 ft [c. 1950 m.] — Phillips. Its range reported to be dwindling owing to clearance of forests for plantations etc.

GENERAL HABITS. Frequents the tops of tall trees, usually on steep hill-sides. Very diurnal in habits, often hunting and calling in broad daylight, but very shy and wary, and seldom seen (Henry).

FOOD. Mainly insects; also mice, small birds, lizards, etc.

VOICE and CALLS. 'A curious note like *krax krax krax krax* (the *r* accentuated) which carries a long distance' (Henry).

BREEDING. *Season*, March-May. *Nest* and *eggs* as in 636 and 637, but normal clutch of 2 eggs, measuring c. 35 × 28 mm.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	122-132	17-18	25-28	56-65 mm (Baker)
1 ♀ (moulting)	157	15	—	64 mm (SDR)

COLOURS of BARE PARTS. Iris yellow. Bill yellowish or greenish horny; cere dusky greenish. Feet greenish olive; soles paler and more yellow.

GLAUCIDIUM CUCULOIDES (Vigors)

Key to the Subspecies

A	Upperparts dark rufous-brown.....	<i>G. a. eastern</i>	291
B	Upperparts blackish brown.....	<i>G. a. cuculoides</i>	299
C	Upperparts more pure brown, less rufous than <i>eastern</i> but more rufous than <i>cuculoides</i>	<i>G. a. reflexus</i>	291

639. West Himalayan Barred Owlet. *Glaucidium cuculoides cuculoides* (Vigors)

Ninox cuculoides Vigors, 1831, Proc. Zool. Soc. London: 8

(Himalayas, i.e. Simla-Almora district)

Plate 54, fig. 6

LOCAL NAMES. *Bēḍi dāḍi* (Hindi); *Tayḥar* (Lepcha).

SIZE. *Myra* ±; length c. 23 cm. (9 in.).

FIELD CHARACTERS. Resembles Barred Jungle Owlet (636) but is larger. A dumpy 'hornless' dark brown (or olive-brown) owlet, closely barred with whitish above and below. Abdomen whitish with longitudinal dark striations. A prominent white throat-patch. Sexes alike.

19

OWLS

291

Weight 2 ♂♂ 159, 169 gm. (GD).

COLOURS of BARE PARTS. Iris lemon-yellow. Bill yellowish green; cere greenish horny. Feet greyish olive-yellow or dull horny green; claws horny brown; pads chrome yellow.

640. East Himalayan Barred Owlet. *Glaucidium cuculoides eastern* Ripley

Glaucidium cuculoides eastern Ripley, 1948, Zoologica 33: 200 (Terai, Mahabhi Hills)
Not in Baker, FBI

LOCAL NAMES. None recorded.

SIZE. *Myra* ±; length c. 23 cm. (9 in.).

FIELD CHARACTERS. As of 639, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Eastern Sikkim, Bhutan, NEFA, Nagaland, from the submontane tract up to c. 2700 m. altitude. Affects open forest of pine, oak, rhododendron, etc.; also subtropical and tropical evergreen jungle in the foothills and dunes.

Extralimital. NW. Burma (Hkakawng Valley).

GENERAL HABITS, FOOD, VOICES and CALLS. As in 639, q.v.

BREEDING. *Season*, *Nest*, *Eggs* as in 639.

MUSEUM DIAGNOSIS. Differs from the nominate western population (639) in being darker and more rufous, i.e. altogether very rufous-brown.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	150-154	20-22	26-29	{ 82-92 mm. 86-94 mm. (SDR, SA)

Glaucidium cuculoides reflexus Baker, 1926, Bull. Brit. Orn. Cl. 47: 59

(Nocog-mi-ban = lat. 24°48'N., long. 93°12'E., Manipur)

Baker, FBI No. 1690, Vol. 4: 445

LOCAL NAME. *Doḥ-kā-sā-rā* (Cachar).

SIZE. *Myra* ±; length c. 23 cm. (9 in.).

FIELD CHARACTERS. As of 639, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Assam hills south of Brahmaputra river (Cachar, Khasi, etc.), Manipur, Mizo (?), Tripura, East Pakistan (Syhet, Chittagong); from the foothills to c. 1300 m. altitude, occasionally to c. 1900 m. Affects open hill forest and tropical evergreen jungle.

Extralimital. N. Burma, N. Laos, N. Vietnam.

290

STRIGIFORMES

Young (immature). Barred only on wings and tail. Generally more rufous, with the head and nape spotted with pale rufous, and underparts streaked.

STATUS, DISTRIBUTION and HABITAT. The entire Himalayas from about Murree in W. Pakistan eastward through Kashmir, Himachal Pradesh, Garhwal, Kumaon, Nepal, and W. Sikkim; from the foothills up to c. 2100 m. — locally to c. 2700 m.; possibly seasonal altitudinal migrant. Affects open forest of pine, oak, rhododendron, etc.; also subtropical and tropical evergreen jungle at the lower elevations.

GENERAL HABITS. Common and largely diurnal; often found sitting out on bare branches or dead tree-stumps in broad sunlight, and hunting freely at all hours of the day. Has been observed perching on a quail (*Gallus chinensis*) flying past, and catching it in the air like a hawk (Dudgen, JBNHS 15: 530). Subjected to relentless chivvying by bullocks, etc., and other small birds as soon as its presence is detected. Six status-like under their mobbing attacks, betraying its agitation only by swinging in tail laterally (from side to side) — for many minutes at a time. Flight, as of other small owls, wavy and dipping — a series of rapid flaps followed by a pause with the wings closed.

FOOD. Beetles, grasshoppers, cicadas, and other large insects; Earth, mice, small birds.

VOICE and CALLS. Heard at all hours during daytime, but is more noisy at dawn and till a couple of hours after sunrise. Normal call, a crescendo of harsh squawks sounding 'as if the bird was trying to rise to some great effort which ends suddenly and unexpectedly' (Osmaston). In the breeding season a continuous bubbling musical whistle *meow-meow-meow* etc. of c. 4 to 7 seconds' duration, reminiscent of the opening notes in the call of the Green Barbet (*Megalaima virens*). Also occasionally a variant of this, *meow-meow*... *teet* as in Barred Jungle Owlet (636).

BREEDING. *Season*, April-May. *Nest*, an unlined natural hollow in a tree-trunk, or a disused or forcibly appropriated barbet- or woodpecker hole. *Eggs*, normally 4, white, round, typical of owls'. Average size of 30 eggs 35.8 × 30.4 mm. (Baker). Presumably both sexes incubate; period and other details unrecorded.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit. Less dark and rufous than *eastern* (640), slight intergrading with which is already apparent in eastern central Nepal.

CHICK. Clothed with short white down all over when first hatched (Titchell).

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	145-162	c. 19-22	c. 24-25	75-90 mm. (Baker)

Birds from Nepal and Sikkim give:

	Wing	Bill (from skull)	Tarsus	Tail
5 ♂♂	143-155	19-21	—	75-85 mm.
9 ♀♀	143-162	19-22	23-30 (2 mod.)	77-88 mm. (53, SA)

292

STRIGIFORMES

GENERAL HABITS, FOOD, VOICES and CALLS. As in 639, q.v. In Assam often frequents bamboo jungle feeding on a species of mouse which also lives in such places (Baker).

BREEDING. *Season*, late March to early June; mainly April-May. *Nest* and *eggs* as in 639 and 640. Normal clutch 4, but frequently 3 and 5 eggs laid. Average size of 46 eggs 36.5 × 30.5 mm. (Baker).

MUSEUM DIAGNOSIS. Much richer rufous-brown than *eastern*; particularly rich rufous on underparts. Breast more streaked, less barred.

MEASUREMENTS

♂ ♀ Wing 141-162 mm. (Baker).

COLOURS of BARE PARTS. As in 639.

Genus *Ninox* Hodgson

Ninox Hodgson, 1837, Madras Jour. Lit. Sci. 5: 23. Type by monotypy.

Ninox *spilargus* Hodgson = *Spilargus* Titchell.

The most hawk-like of all the owls owing to the rufous and facial disc being quite obsolete. Cere swollen and non-tubular; nostril placed close to its anterior margin. Wing long and more pointed than in *Glaucidium* or *Adonia*; 1st and 4th primaries (an.) longest; 1st about = 7th. Tail moderately long; rounded at tip. Tarsus feathered; upper surface of toes thinly covered with bristles.

Genus found throughout the Oriental Region, the greater part of the Australian Region, New Zealand, and Madagascar. Two species within Indian fauna.

SIZE. *Myra* ±; length c. 32 cm. (12½ in.).

OWLS

293

FIELD CHARACTERS. A very hawk-like owl, dark greyish brown above, with whitish forehead and irregular white patches about the shoulders.

x c. 1/2

Below, throat and foreneck fulvous, streaked with brown; rest of underparts white with large drops of reddish brown forming broken bars. Tail barred with black and tipped with white. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Resident. The outer Himalayas and submontane tracts from about Murree in W. Pakistan eastward through Nepal, Sikkim, and Bhutan

to NEFA and Assam north of Brahmaputra river. Southward, excepting the arid tracts in the northwest (Sind, Rajasthan, N. Gujarat), widely but locally distributed through northern and central India, east to Bengal, Orissa, and N. Andhra. Southern limit uncertain: an example collected in Greater Bombay (c. 19°N. lat.) is intermediate between this and *hirsuta*, while 2 specimens from Madras (c. 13°N. lat.) in the B.M. seem referable to this paler northern race. Has been recorded in the past from Mt. Abu, but no recent confirmation thence; may occur in Gir forest, Saurashtra. Affects forest, well-wooded country, and groves of trees, particularly in the neighbourhood of water and lining forest streams and nullahs — often close to habitation.

GENERAL HABITS. Crepuscular and nocturnal. Keeps singly or in pairs which spend the daytime cuddled close together up in the seclusion of a shady branch often thickly smothered with creepers. But when disturbed will readily fly out to another tree through the dappled sunshine without any apparent discomfort. Flight (rapid wing-beats and glides), and manner of alighting at the end of it — sweeping upward to settle on a branch — characteristically hawk-like. Is normally not abroad before darkening dusk, but may sometimes be on the move during daytime in cloudy weather. Perches upright on a post or tree-stump at dusk — usually the same, night after night — keeping a look-out for prey, from time to time springing up vertically a metre or more in the air to take a passing insect in its claws, and diving back to the perch in the manner of a bulbul catching winged termites. Also flies about in the gathering dusk like a nightjar, hawking beetles in the air.

FOOD. Large insects such as beetles and grasshoppers; frogs, lizards, small birds, mice, and occasionally (or regularly?) small bats.

VOICE AND CALLS. Very distinctive and diagnostic. A rather soft and pleasant, almost musical, *oo . . uk, oo . . uk, oo . . uk*, etc. in runs of 6 to 20 calls (mostly 9 to 13) at the rate of about one per second, with a pause of a few seconds between each run. Very vocal during the breeding season, calling more or less continuously for hours on end, particularly during moonlit nights. Two birds (♂ and ♀?) will join in irregular duets, or several birds in the distance will answer one another from all directions. Has a specially noisy round of calling in the twilight of dawn before retiring for the day. In cloudy weather occasionally also calls in daytime.

Strix hirsuta Temminck, 1824, Pl. col., livr. 49, pl. 289 (Ceylon)
Baker, FBI No. 1702, Vol. 4: 457

LOCAL NAMES. *Chāghād bāra* (Hindi); *Pāḍḍigānta vestam* (Telugu); *Pūnchi bayā* (Sinhala); *Sirna āndai* (Tamil); *Pillundhē* (Malayalam).

SIZE. Pigeon ±; length c. 32 cm. (12½ in.).

FIELD CHARACTERS. As of 642, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Southern India from about the latitude of Bombay (c. 19°N.) through Maharashtra, Goa, Mysore, western Tamil Nadu and Kerala. How far east needs to be determined since two specimens from Madras city in the British Museum appear to belong to the northern form *lugubris*! Resident in all zones in Ceylon; locally and sparsely distributed throughout the lowlands and up to c. 1300 m. in the hills. Affects forest and well-wooded country, and kampongs around habitations, e.g. in Kerala.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 642 and 643, qq.v.

BREEDING. Season, January to May; in Ceylon March–April and also in November. *Nest and eggs* (2 or 3) as in 642.

MUSEUM DIAGNOSIS. Very like *burmanica* (643) but still darker. Head always darker than back and more slaty brown, less red-brown. *Below*, very richly coloured; under wing-coverts and axillaries profusely barred with dark brown.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂ ♀	190-212	22-24 (from skull)	24-28	112-122 mm. (SA, HW)

Weight c. 8 oz. (227 gm.). — Hume.

Ninox obscura Hume, 1872, Stray Feathers 1: 11 (Camorta, Nicobars)
Baker, FBI No. 1703, Vol. 4: 457
Plate 54, fig. 13

LOCAL NAMES. None recorded.

SIZE. Pigeon —; length c. 31 cm. (12 in.).

FIELD CHARACTERS. As of 642, q.v., but overall deep chocolate-brown. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident. Andaman and Nicobar Islands. Affects forest about the settlements, and rubber plantations, etc.

294

STRIGIFORMES

BREEDING. Curiously enough almost nothing known concerning this race beyond that Osmaston once found its eggs 'in a large hole in a mango tree c. 8 ft. up in a compound in Dehra Dun' on 1 July. The 4 eggs measured c. 36 × 31 mm.

MUSEUM DIAGNOSIS. See Key to the Subspecies; for details of plumage Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	215-227	c. 21-22	c. 24	124-135 mm. (Baker)
Nepal birds give				
		(from skull)

2 ♀♀	218-219	21-24	—	126-133 mm. (BB)

Weight 1 ♀ 186 gm. (GD).

COLOURS OF BARE PARTS. Iris bright golden yellow. Bill horny slate or bluish black, paler at tip; cere dull green or greenish brown. Feet dull yellow or yellowish green.

643. Burmese Brown Hawk-Owl. *Ninox scutulata burmanica* Hume

Ninox burmanica Hume, 1876, Stray Feathers 4: 285 (Pegu and Tenasserim)
Baker, FBI No. 1699, Vol. 4: 455

LOCAL NAME. *Māh sorāi* (Assam).

SIZE. Pigeon ±; length c. 32 cm. (12½ in.).

FIELD CHARACTERS. As of 642, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Assam south of Brahmaputra river, Nagaland, Manipur, Mizo, Tripura, East Pakistan; from the lowlands to c. 1700 m. Affects forest and well-wooded country, and kampongs around habitations; often groves of trees in jungly gardens within urban limits.

Extralimital. Southern Yunnan, south to the Malay Peninsula, Thailand, and all the Indo-Chinese countries.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 642. Captures the fast and erratically flying pipistrelle bats on the wing, going through all manner of agile aerial contortions in the chase (McCann, JBNHS 36: 1002). 'Flight something similar to a woodcock's; often come across when beating patches of jungle for that bird' (Wickham, ibid. 34: 63).

BREEDING. Season, end March to early June. *Nest*, a natural hollow in a tree-trunk, unlined but usually littered with cast-up food pellets. *Eggs*, 3 or 4, exceptionally 5, white, roundish, typical. Average size of 50 eggs 35.1 × 29.5 mm. (Baker). Both sexes believed to incubate; incubation period in one case 24 days.

MUSEUM DIAGNOSIS. Differs from *lugubris* (642) in being darker both above and below. Head as dark as or darker than back, and much less grey. *Below*, dark markings usually richer and larger, but this subject to considerable individual variation.

296

STRIGIFORMES

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 642 and the other races, qq.v. Beetles and grasshoppers mentioned as the two chief food items.

BREEDING. Little recorded beyond that B. B. Osmaston had a young one brought to him on 30 May.

MUSEUM DIAGNOSIS. Differs from the other races in being dark chocolate-brown, somewhat paler and rufous on abdomen. Forehead mixed black and white; head and primary coverts generally darker and blacker than rest of upperparts. A few small whitish spots and bars on flanks and abdomen (visible only on lifting the overlying feathers).

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	197-220	c. 22-23	c. 28	120-126 mm. (Baker)

COLOURS OF BARE PARTS. As in 642 and other races.

NINOX AFFINIS Beavan

Key to the Subspecies

Wing under c. 170 mm.	<i>N. a. affinis</i>
Wing over c. 180 mm.	<i>N. a. isolata</i>

646. Andaman Brown Hawk-Owl. *Ninox affinis affinis* Beavan

Ninox affinis 'Tyler' = Beavan, 1867, Ibis: 316
(Aberdeen Point, Port Blair, Andaman Islands)
Baker, FBI No. 1700, Vol. 4: 456

LOCAL NAMES. None recorded.

SIZE. Pigeon —; length c. 28 cm. (11 in.).

FIELD CHARACTERS. Overall as of 642, q.v. but smaller and very brown, with distinctive bright rufous-brown spotting on the underparts. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident; Andaman Islands. Distribution within the group not worked out.

GENERAL HABITS, FOOD, VOICE AND CALLS. Nothing specifically recorded; presumably habits largely as in the species *scutulata*, but call described by A. L. Butler (*vide* Blanford, 4: 485) as 'a loud *craw* something like a *Glauclidium*'s note and quite different from that of *N. scutulata* in Ceylon which is a soft fluty disyllable, as is also that of *N. obscura*'.¹

BREEDING. Unknown.

MUSEUM DIAGNOSIS. Under wing-coverts and axillaries normally almost unspotted orange-rufous, but occasionally the former more or less barred.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	167-169	c. 20	c. 27-28	102-106 mm. (Baker)

COLOURS OF BARE PARTS. Iris yellow. Bill blackish, paler and greenish on culmen and tip; cere dull green. Feet yellowish; claws black.

¹ This, if correct, is another good reason for treating *obscura* as a race of *scutulata* and *affinis* as a distinct species, as has here been done.

647. Nicobar Brown Hawk-Owl. *Ninox affinis isolata* Baker

Ninox scutulata isolata Baker, 1926, Bull. Brit. Orn. Cl. 47: 60 (Car Nicobar)
Baker, FBI No. 1701, Vol. 4: 456

LOCAL NAMES. None recorded.

SIZE. Pigeon —; length c. 28 cm. (11 in.).

FIELD CHARACTERS. As of 646, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident; Nicobar Islands. So far known from Car Nicobar, Trinkat, and Camorta. Great Nicobar (?).

GENERAL HABITS, FOOD, VOICE and CALLS. Nothing specifically recorded beyond that Davison observed and shot a specimen hawking moths like a nightjar in low secondary jungle late in the evening.

BREEDING. Unknown.

MUSEUM DIAGNOSIS. Similar to 646 but distinctly larger and browner, less ashy on the upperparts.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂ ♀	185-205	c. 22 (from feathers)	c. 27-28	118-130 mm. (Baker)

COLOURS OF BARE PARTS. As in 646.

Genus *ATHENE* Boie

Athene Boie, 1822, Isis von Oken, Bd. 1, col. 549. Type, by subsequent designation, *A. noctua* (Retz.) Boie, Pl. enl. 439. *Str. pastarina* auct. = *Strix noctua* Scopoli
Heteroglaux Anonymous = Hume, 1873, Stray Feathers 1: 467. Type, by monotypy, *Heteroglaux blewitti* Hume

Contains small owls without ear-tufts with the upper plumage more or less spotted with white. No distinct facial disc or ruff. Cere swollen; nostril a round orifice near its anterior margin. Wing rounded; 3rd primary (as.) longest; 1st primary between 5th and 8th. Tail moderate. Tarsus feathered to the toes which are also covered above with feathers and bristles.

Genus found throughout central Europe, N. Africa, and south and central Asia to China.

Key to the Species

	Page
A Abdomen longitudinally streaked..... <i>A. noctua</i>	297
B Abdomen transversely barred.....1	
1 Crown distinctly spotted; back widely interspersed with subterminal spots; tail narrowly banded with white, less than 5 mm. in width; collar-band broken below; white throat-patch smaller; 1st primary (as.) longer than 6th; skull and feet smaller..... <i>A. brama</i>	299
2 Crown unspotted or faintly spotted on the feather shafts; back plain, spotting much reduced; tail broadly banded with white, more than 5 mm. in width; collar-band continuous; white throat-patch larger, extending to centre of abdomen; 1st primary (as.) equals 7th or shorter than 8th; skull and feet more massive..... <i>A. blewitti</i>	302

ATHENE NOCTUA (Scopoli)

Athene noctua ludlowi Baker, 1926, Bull. Brit. Orn. Cl. 47: 58
(Dochon, 15,000 ft., Rhamto Lake, Tibet)
Baker, FBI No. 1688, Vol. 4: 443

LOCAL NAME. *Ugpa* (Tibet).

SIZE. Myna; squatter, with shorter tail. Length c. 23 cm. (9 in.).

FIELD CHARACTERS. As of 648, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Ladakh (ssp.?) eastward probably through the Tibetan plateau facies of N. Sikkim, N. Bhutan, and northern NEFA, from c. 3000 to 4600 m. alt. Affects clay cliffs and bluffs of rivers and outscoured watercourses, stone walls of ruins, etc.

Extralimital. Tibet.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 648, q.v.

BREEDING. Not recorded within our limits. Ludlow took 2 eggs from a nest in a hole under the eaves of an inhabited Tibetan house near Gyantse (at c. 3750 m.) on 9 May, measuring c. 37 × 29 mm.

MUSEUM DIAGNOSIS. Differs from *A. n. bactriana* (648) in being darker and larger.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
		(from feathers)		
♂ ♀	169-173	18-20	31-32	88-96 mm. (Baker)

COLOURS OF BARE PARTS. Iris yellow. Bill bright yellow. Feet grey; soles yellow (F. M. Bailey).

ATHENE BRAMA (Temminck)

a Spotted with white..... <i>A. b. brama</i>	302
Spotting considerably reduced..... <i>A. b. ultra</i>	301

650. Northern Spotted Owllet. *Athene brama indica* (Franklin)

Noctua indica Franklin, 1831, Proc. Zool. Soc. London: 115 (Banks of the Ganges and in the mountain chain of upper Hindoostan, i.e. Uttar Pradesh)
Baker, FBI No. 1684, Vol. 4: 440

LOCAL NAMES. Ooloo, *Khākūwāi*, *Khūāthia*, *Chūghād* (Hindi); *Pēncha* (Bihar); *Kūhīrā pēncha* (Bengal); *Dang tang pum* (Lepcha); *Chibīrā* (Sind).

SIZE. Myna ±; length c. 21 cm. (8 in.).

648. Hutton's Owllet. *Athene noctua bactriana* Blyth

Athene bactriana Blyth, 1848, in Hutton, Jour. Asiat. Soc. Bengal 16 (2): 776
(Old Kandahar, Afghanistan)
Baker, FBI No. 1687, Vol. 4: 442
Plate 54, fig. 10

LOCAL NAMES. None recorded.

SIZE. Myna; squatter, with shorter tail. Length c. 23 cm. (9 in.).

FIELD CHARACTERS. A small, squat, round-headed owl.

Adult. Above, sandy brown spotted with white; face 'pepper-and-salt' with pure white supercilia; a conspicuous white collar on hindneck; wings and tail broadly banded with white. Below, white, longitudinally streaked with reddish brown on breast and abdomen; a pale brown collar across throat. Sexes alike.

Young (immature). Paler than adult and more streaked with white above and on wings.

STATUS, DISTRIBUTION and HABITAT. Resident and fairly common: Baluchistan (Makran (?), Kalat, Chagai, Quetta, Chaman, etc.) and northward along the Afghan frontier (Thal, Kohat, etc.) from plains level to c. 3000 m. altitude. Affects bare, open semi-desert country living in bleak places in holes in earth-cliffs and high bluffs of rivers, rocks, and ruined walls, etc. Also visits gardens in cantonments (Quetta, Christison).

Extralimital. Transcaspia eastward to the plains of the Syr Darya, and southward to Iraq, Iran, Afghanistan.

GENERAL HABITS. Very similar to those of the commoner and more familiar Spotted Owllet (650), q.v. Usually keeps in pairs, or family parties of 3 or 4. Largely crepuscular and nocturnal, but quite wide awake during daytime, sitting about on posts and telegraph wires and flying—even hunting—in the heat and glare of broad sunshine without any apparent discomfort.

FOOD. Beetles and other insects, lizards, small birds, and mice, etc.

VOICE and CALLS. A shrill but not unpleasant, rather plaintive *peep*, repeated every few seconds. Presumably also other calls, but not recorded.

BREEDING. Season (in Baluchistan) March to June. Nests in holes in earth-cliffs, rocks, crumbling walls, or trees. Eggs, 3 to 5 or 6, white, round, typical of owls, c. 32 × 28 mm.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit. Presents a wide range of individual variation, the colour ranging from the normal greyish or sandy brown to dark brown or dark reddish brown, partly but not entirely due to freshness or wear. Feathering on toes also very variable: in freshly moulted birds always more feathered, in worn ones more bristly.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
		(from feathers)		
♂ ♀	156-168	c. 18-20	c. 32	84-87 mm. (Baker)

Paludan (1959) gives for Afghan birds: Wing 8 ♂♂ 157-170; 3 ♀♀ 169-174 mm. Weight 138-172 gm.

COLOURS OF BARE PARTS. Iris pure sulphur-yellow. Bill greenish yellow; cere pale greenish white. Feet greenish; claws horny black (Stoliczka).

FIELD CHARACTERS. A familiar squat, white-spotted greyish brown little owl with the typical large round head (no ear-tufts) and yellow forwardly directed staring eyes. Sexes alike.

Young (immature). Above, much more marked with white, the spots running into definite bars. Below, from breast down the dark markings are longitudinal.

STATUS, DISTRIBUTION and HABITAT. Resident and generally common. From the Afghan frontier (Kohat and Peshawar dists.) eastward through

Punjab and Jammu in the plains and along the Himalayan submontane tract (terai, duns — locally up to c. 1400 m.) through Nepal, Sikkim, Bhutan to Assam north and south of Brahmaputra river (excepting Lakhimpur dist.); Manipur, East Pakistan (Chittagong and Dacca dists.); Makran, Baluchistan (Sibi and Quetta dists.), Sind, Rajasthan, and east through the entire Gangetic Plain. Kutch, N. Gujarat, and all continental India south to the 20th parallel, the boundary arbitrarily fixed for convenience. Affects the neighbourhood of villages and cultivation, mango topes, groves of ancient trees, and ruins. Avoids heavy forest. In semi-desert areas where suitable trees are scarce, appropriates cavities in the sides of ravines and earth-cliffs, like *Athene noctua*.

Extralimital. Southeastern Iran (Bampur).

GENERAL HABITS. Keeps in pairs or family parties of 3 or 4. Largely crepuscular and nocturnal, but is frequently abroad — and even hunting — in the full glare of noonday. The nocturnal habit is evidently not so much because of intolerance to sunlight as in order to escape the merciless mobbing and chivvying it receives from all diurnal birds the moment it is discovered. Normally retires at sunrise to the seclusion of a tree-hollow or some leafy branch, the pair sitting cuddled closely together. In some localities almost every venerable banyan, tamarind or mango tree will hold a resident pair or two of these little owls, and one has but to tap on the trunk to bring up an inquiring and surprised little staring face to the entrance of a hollow, or dislodge a pair from some shady recess. The birds betray their presence by dashing out fustily to a neighbouring branch whence they bob and stare at the intruder in clownish fashion, with the head often screwed completely round.

Issues from its retreat at dusk to perch on fence-posts, telegraph wires and other points of vantage to look out for prey, pouncing from time to time on some unwary insect, or flying noiselessly across from 'pillar to post'. Will occasionally launch ungainly aerial sallies to catch winged termites in its claws, and sometimes even hover clumsily for a few seconds to spy creeping prey. Commonly uses street lamps as hunting bases, hawking the beetles and moths attracted to the light as they flutter in the circle of illumination, and returning to the perch. Here the quarry is dismembered and devoured, the bird raising one foot to its bill and dealing with the insect as a parakeet does with a nut. Flight, as of other small owls, deeply

OWLS

301

undulating, consisting of a few rapid flaps followed by a dip with the wings pressed to the sides.

FOOD. Chiefly beetles, moths, locusts, and other insects; also earthworms, lizards, mice, and small birds. Among insects the following are some that have been identified at Pusa Agricultural Research Institute: *Chrotogonus* spp., *Brachytrypus achatinus*, *Cryllotalpa africana*, *Cathartus sabaeus*, *Onthophagus spissifer*, and various coprids and carabids (Mason & Lefroy, 1912).

VOICE AND CALLS. A harsh screechy *chirurr-chirurr-chirurr* etc. followed by or alternated with *cheevak, cheevak, cheevak*, and a variety of equally discordant screeches and chuckles. Particularly noisy in breeding season.

BREEDING. *Season*, February to April. *Nest*, a natural hollow in a tree-trunk, a hole in a dilapidated wall, or between the ceiling and roof of deserted as well as occupied dwellings — sometimes lined with a little grass, tow, and feathers. *Eggs*, 3 or 4, occasionally 5, white, roundish ovals. Average size of 50 eggs 32.2 × 27.1 mm. (Baker). Both sexes share in lining the nest, incubation, and tending the young. Incubation period undetermined.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

Chick (in down). 'Pure white, short and very soft pre-pennae cover body, except apterions of lateral neck, lateral body in front, and each side of spinal tract above. Some preplumulae of same type of down on lateral apteria in front' (Ticehurst).

Moult. Post-nuptial moult complete and no spring moult. Post-juvénal moult apparently does not include wings and tail.

MEASUREMENTS of a series from Punjab and Nepal:

	Wing	Bill (from skull)	Tail
18 ♂♂	153-169	19-22	75-84 mm.
8 ♀♀	159-171	18-23	74-84 mm. (HW, RB)

Tarsus 4 ♂ 30-32 mm.; middle toe (without claw) 16.5-18 mm. (SDR).
Weight 1 ♂ 114 gm. (GD).

COLOURS OF BARE PARTS. Iris pale to deep golden yellow. Bill greenish horny, sometimes darker sometimes more yellow on culmen; cere dusky green or greenish brown. Feet dirty yellowish green; claws dark horny; sole pads yellowish white.

651. East Assam Spotted Owllet. *Athene brama ultra* Ripley

Athene brama ultra Ripley, 1948, Proc. Biol. Soc. Washington 61: 100
(Chabua, N. Lakhimpur dist., NE. Assam)
Not in Baker, FBI

LOCAL NAMES. None recorded.

SIZE. Myna ±; length c. 21 cm. (8 in.).

FIELD CHARACTERS. As of 650, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Lakhimpur dist., NE. Assam north and south of Brahmaputra and Lohit rivers. Affects groves of ancient trees in and about towns and villages.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 650. 'Call distinctly harsher and more high-pitched than either *A. b. brama* or *A. b. indica*' (SDR).

OWLS

303

FIELD CHARACTERS. Very like Spotted Owllet (650) but larger though with shorter wings.

Adult. *Above*, whole head, back sides of neck, scapulars, and interscapular region unspotted dark earthy brown; hind collar of white spots ill defined. *Below*, a strongly marked dark brown bar across throat; underparts more brown less white; breast brown with merely white fringes to the feathers. *Sexes* alike. (For details see Ripley, S.D., 1976, JBNHS 73: 1-4.)

STATUS, DISTRIBUTION AND HABITAT. Rare but apparently extending all along the Satpura mountain trend for over 1100 km. from Surat Dangs and W. Khandesh to eastern Madhya Pradesh and the Sambalpur area in Orissa. Since first described in 1873 less than a dozen specimens have been collected, the latest in October 1914 at Mandvi on Tapti river (21°16'N., 73°22'E.), c. 220 km. north of Bombay, by Meinertzhagen. Affects heavy moist deciduous jungle and groves of wild mango; partial to the neighbourhood of streams.

GENERAL HABITS. Very little known. Evidently a fairly diurnal and shy forest representative of the Spotted Owllet. Some of the specimens were shot in heavy jungle below the Satpuras late in the morning while sitting alone on the exposed tops of thin trees. 'Not uncommon in this dense jungle' (West Khandesh — J. Davidson, SF 10: 292).

FOOD, VOICE AND CALLS, BREEDING. Not recorded.

MUSEUM DIAGNOSIS. See Key to the Species. Tarsus feathered; upper surface of toes with soft feathers, the barbs of which wear away, leaving the shafts only in some specimens (Blanford).

	Wing	Bill (from cere)	Tarsus	Tail	Middle toe (without claw)
3 ♂♂	145-154	14-15	33-35	68-72.5	20-23 mm.
2 ♀♀	147.5, 148	15.5, 16	34.5, 37	63, 70	21, 21 mm. (SDR)

Weight of one ♂ 8½ oz. (241 gm.) — Blanford.

COLOURS OF BARE PARTS. Iris bright yellow. Rest not recorded.

Genus *STRIX* Linnaeus

Strix Linnaeus, 1758, Syst. Nat., ed. 10, 1: 92. Type, by tautonymy, *Strix stridula* Linnaeus (*Strix*, prebinomial specific name in synonymy) = *Strix aluco* Linnaeus. No ear-tufts (aigrettes); ear furnished with an operculum. Bill stout. Tarsus thickly feathered throughout; toes feathered above to base of last phalanx; claws strong. Ruff narrow, incomplete above; facial disc well developed, extending almost as far above eyes as below. Wings rounded: 3rd, 4th, and 5th primaries (as) longest. Tail of moderate length, rounded. Irides always dark.

Genus represented over the greater part of the world; within our limits by four species.

302

STRIGIFORMES

BREEDING. Unrecorded. Presumably not different from 650.

MUSEUM DIAGNOSIS. Differs from *indica* by somewhat larger size and darker coloration, with the white spotting considerably reduced.

MEASUREMENTS

2 ♂♂ Wing 164-167; bill (from cere) 15-16; tail 83-93 mm. (SDR).

COLOURS OF BARE PARTS. As in 650.

652. Southern Spotted Owllet. *Athene brama brama* (Temminck)

Strix brama Temminck, 1821, Pl. col., livr. 12, pl. 68

(Pondicherry and west coast of India)

Carina brama fryi Baker, 1919, Bull. Brit. Orn. Cl. 40: 60

(Rameswaram, Madras, India)

Baker, FBI No. 1683, Vol. 4: 439

Plate 54, fig. 12

LOCAL NAMES. *Pāḍḍigani* (Telugu); *Pūllī Endā* (Tamil); *Pingā* (Marathi); *Chibri* (Gujarati).

SIZE. Myna ±; length c. 21 cm. (8 in.).

FIELD CHARACTERS. As of 650, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident. Peninsular India south of 20°N. lat., the boundary fixed for convenience between the northern and southern populations which intergrade around this parallel. Affects ruins, mango topes and groves of ancient trees, etc. in and around towns, villages and cultivation.

Curiously enough not found in Ceylon though occurring on Rameswaram I. only c. 30 km. from its northern tip!

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 650, q.v.

BREEDING. *Season*, chiefly November to March. *Nest* and *eggs* (3 or 4) as in the northern form. Average size of 40 eggs 31.6 × 27.4 mm. (Baker). Eggs apparently laid at irregular intervals, and incubation starts from the first egg, resulting in considerable disparity in the growth of nestlings in the same brood, and mortality amongst the youngest and weakest.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit. Differs from the northern race *indica* in being considerably darker and smaller.

MEASUREMENTS of a series from South India (Kerala, Mysore, Tamil Nadu):

	Wing	Bill (from skull)	Tail
12 ♂♂	141-158	19-21	66-72 mm.
12 ♀♀	151-157	20-22	68-74 mm. (HW, SA)

Tarsus c. 27-28 mm.

COLOURS OF BARE PARTS. As in 650.

653. Forest Spotted Owllet. *Athene blewitti* (Hume)

Heteroglaux Blewitti Anonymous = Hume, 1873, Stray Feathers 1: 468

(Buznah, Phooljan State, India) [= Phuljhar, c. 21°N., 83°E., Madhya Pradesh]

Baker, FBI No. 1651, Vol. 4: 441

LOCAL NAMES. None recorded.

SIZE. Myna ±; length c. 23 cm. (9 in.).

STRIGIFORMES

304

654. Hume's Wood Owl. *Strix butleri* (Hume)

Asio butleri Anonymous = Hume, 1878, Stray Feathers 7: 316

(Omara, [= Ormara], Mekran Coast, southern Baluchistan)

Baker, FBI No. 1651, Vol. 4: 404

Plate 53, fig. 10

LOCAL NAMES. None recorded.

SIZE. Pigeon +; length c. 36 cm. (14 in.).

FIELD CHARACTERS. Like a small Himalayan Wood Owl (662), but conspicuously paler and less streaked on the underparts.

Adult. *Above*, no ear-tufts; facial disc tawny white; ruff greyish brown finely stippled with buff. Upperparts chiefly brown irregularly banded and splodged with brownish buff; a distinct golden buff collar on upper back. *Below*, creamy white, the feathers edged at tip with rufous brown; narrow brown shaft-streaks on breast and upper abdomen. *Sexes* alike.

STATUS, DISTRIBUTION AND HABITAT. Very rare. Only a single record (the type) from Ormara, Makran coast, W. Pakistan.

Extralimital. Known only from individual specimens from Sinai Peninsula, SE. Palestine, and Arabia (Mahd Dhahab, c. 400 km. NNE. of Jiddah). Evidently very rare everywhere.

GENERAL HABITS, FOOD. Not described.

VOICE AND CALLS. 'An unmistakable clear long-drawn *huu* uttered at intervals, sometimes varied by a tremulous and more throaty hoot as in *Strix aluco*' (Meinertzhagen).

BREEDING. Unknown.

MUSEUM DIAGNOSIS. 3rd primary (as) longest; 4th very little shorter. Slender tarsi and small feet and claws striking. For details of plumage see Baker, loc. cit.

MEASUREMENTS. Wing 5 ♂ 251-257 mm. (Meinertzhagen). Bill (from feathers) 28; tarsus 57; tail 144 mm. (of the type specimen) — Baker.

COLOURS OF BARE PARTS. Not recorded.

(Sasan, Junagadh, Kathiawar, W. India)

Baker, FBI No. 1649 (part), Vol. 4: 402

LOCAL NAME. *Girāri ghārd* (Gujarati).

SIZE. Pariah Kite ±; dumper and with shorter tail. Length c. 48 cm. (19 in.).

FIELD CHARACTERS. As of 657, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Saurashtra peninsula, Gujarat. Affects mango topes, and groves of ancient tamarind trees, etc. near villages and cultivation.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 657, q.v.

BREEDING. Season, nest, and eggs as in 657.

MUSEUM DIAGNOSIS. 'Differs from nominate *ocellata* (657) in being much larger; similar in coloration, but averaging greyer above; size of black areas on back and nape reduced' (Koelz).

MEASUREMENTS

2 ♂♂ Wing 360, 372; tail 197, 203 mm. (Koelz).

COLOURS OF BARE PARTS. As in 657.

656. Northern Mottled Wood Owl. *Strix ocellata grisescens* Koelz

(Nichlaul, U.P. (NE. of Gorakhpur), N. India)

Baker, FBI No. 1649 (part), Vol. 4: 402

LOCAL NAMES. None recorded.

SIZE. Pariah Kite ±; dumper and with shorter tail. Length c. 48 cm. (19 in.).

FIELD CHARACTERS. As of 657, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident and widely distributed. The northern part of the subcontinent from the base of the Himalayas south to an undetermined boundary; from c. 74°E. long. in the Punjab (Lahore), and Jammu, south through Rajasthan, eastward across the Gangetic Plain (Uttar Pradesh, Bihar, W. Bengal). Not Assam or East Pakistan (?). Affects mango topes, groves of ancient banyan, tamarind, and suchlike densely foliated trees about village homesteads and cultivation.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 657, q.v.

BREEDING. Season, chiefly February and March. Nest and eggs as in the nominate race (657). Eggs not measured separately from those of *ocellata*.

MUSEUM DIAGNOSIS. 'Differs from *ocellata* by slightly larger size and lighter coloration of the upperparts. Black bars on scapulars, wing- and tail-feathers narrower; the black and white spots in the rufous area of the neck mostly white, while they are largely black in *ocellata*; rufous parts of plumage often paler' (Koelz).

MEASUREMENTS

Wing ♂♂ 338-346 mm. (Koelz).

COLOURS OF BARE PARTS. As in 657.

657. Southern Mottled Wood Owl. *Strix ocellata ocellata* (Lesson)

LOCAL NAME. Kollikkūraṇ (Malayalam).

SIZE. Pariah Kite ±; dumper and with shorter tail. Length c. 48 cm. (19 in.).

COLOURS OF BARE PARTS. Iris dark brown; eyelids (fine rim) dusky pink or dull coral-red. Bill horny black, paler at tip; mouth pale yellowish pink. Feet brownish flesh or dirty yellowish brown; claws horny black; soles yellow.

STRIX LEPTOGRAMMICA Temminck

Key to the Subspecies

	Page
Facial disc rufous; wing c. 291-348 mm.....	<i>S. l. indranee</i> 308
Facial disc white; wing c. 382-412 mm.....	<i>S. l. newarensis</i> 307

658. Himalayan Brown Wood Owl. *Strix leptogrammica newarensis* (Hodgson)

Uluia newarensis Hodgson, 1836, Asiat. Res. 19: 168 (Nepal)

Baker, FBI No. 1647, Vol. 4: 400

LOCAL NAMES. Būlākā (Nepal); Mik dab bru (Lepcha).

SIZE. Pariah Kite —; dumper. Length c. 53 cm. (21 in.).

FIELD CHARACTERS. A large brown owl with close-barred underparts, whitish facial disc framed with brown, and no ear-tufts. A prominent white supercilium.

Adult. Above, chocolate-brown; scapulars, wings and upper tail-coverts barred with white. Tail brown, barred with fulvous and tipped with white. Below, chin mixed chocolate and white; a pure white patch on throat. Rest of lower plumage pale fulvous or buffy white suffused with brownish on breast, and closely barred with dark brown. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Resident throughout the Himalayas from W. Pakistan (Punjab) through Himachal Pradesh, Garhwal, Kumaon, Nepal, Sikkim, Bhutan (?) and NEFA (?) from c. 750 to 2450 m. alt. (recorded from c. as high as 4000 m.). Also Garo, Khasi, Cachar, Naga and Manipur hills. Affects deep forest.

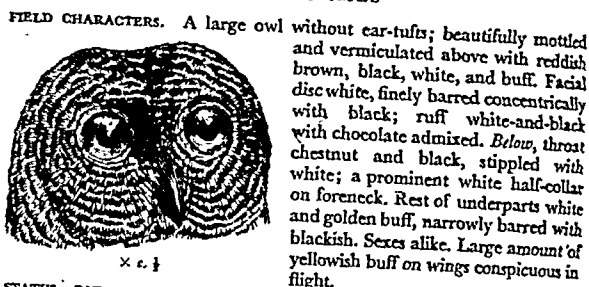

Extralimital. N. and C. Burma, N. Thailand (evidently this race).

GENERAL HABITS, FOOD, VOICE and CALLS. Nocturnal. Keeps in pairs within heavy forest during daytime; this perhaps more to escape mobbing by diurnal birds than from any disability caused by sunshine. Very shy; easily disturbed at its daytime retreat by the faintest footfall, flying away swiftly and noiselessly from the intruder, threading its way through the welter of tree-trunks and branches with ease, and moving on further at longer and longer distances if followed.

FOOD. As in 659. Rat, dove and jungle myna identified among stomach contents.

VOICE and CALLS. 'A low double hoot tu-whoo' (S. L. Whympers). '(1) Very much like that of a male domestic pigeon, (2) a low sonorous squawk, possibly an alarm note, (3) a loud snapping of the bill when annoyed' (A. E. Jones). Sometimes calls also during daytime.

BREEDING. Season, January to March. Nest, of a few sticks and feathers in the hollow of a forking tree-trunk, on a shelf in a cliff-face, or shallow

× c. 1

STATUS, DISTRIBUTION and HABITAT. Resident and widely distributed throughout peninsular India from southern Kerala and Tamil Nadu northward through Mysore, Andhra, Maharashtra, Gujarat, Madhya Pradesh, Orissa; zone of diffusion with the northern population (*grisescens*) undetermined. Does not occur in Ceylon. Affects lightly wooded plains country; partial to mango topes, groves of ancient tamarind, banyan, and suchlike densely foliated trees on the outskirts of villages, homesteads, and cultivation.

GENERAL HABITS. Largely nocturnal. Pairs spend the day sitting together and dozing on some secluded branch hidden in the foliage. But when disturbed will fly long distances in bright sunlight without any apparent discomfort. At the end of the flight sweeps upwards to settle well within the seclusion of the foliage canopy, unlike *Bubo* which prefers to alight on the peripheral branches.

FOOD. Rats, mice, and other rodents; birds up to size of blue rock pigeon; lizards, crabs, beetles and other large insects. In one stomach was found a large scorpion (*Buthus*?) complete with sting!

VOICE and CALLS. In the breeding season, particularly, a loud quavering eerie *chūhū-aa* uttered regularly as the birds emerge from their daytime retreat, and again before retiring at dawn; also from time to time during the night, but not very frequently. At other seasons mostly a single mellow, metallic hoot. An occasional harsh screech similar to the Barn Owl's.

BREEDING. Season, November to April. Nest, a natural tree-hollow, practically unlined. Has been recorded building a stick nest like Dusky Horned Owl (630); but this very unusual. Eggs, normally 2, occasionally 3, creamy white, roundish. Average size of 18 eggs 51.1 × 42.6 mm. (Baker). Share of the sexes in incubation, incubation period, and other details unknown.

MUSEUM DIAGNOSIS. Characterized by a dark brown patch running back from the eye on either side of the neck. For details of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂♀ 320-345		36-39	54-56	174-201 mm. (Baker)
6 recent specimens from Gujarat and S. India give				
♂♀ 333-357		38-42 (from skull)	61-65	177-193 mm. (SA, HW)

scrape in the bare ground at the foot of a rock or large tree in some shady ravine. Eggs, normally 2, sometimes only a singleton, white, roundish oval. Average size of 16 eggs 56.2 × 45.9 mm. (Baker). Share of the sexes in the domestic chores, incubation period, and other details unknown.

MUSEUM DIAGNOSIS. Differs from the peninsular race *indranee* (659) in being much larger, with the facial disc whitish or only faintly fulvous; supercilium a purer white; terminal band on tail-feathers generally more white; underparts less fulvous, more white.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂♀ 382-412		c. 40-45	c. 53-56	229-335 mm. (Baker)

Plate 53, fig. 4

LOCAL NAME. Kollikkūraṇ (Malayalam).

SIZE. Pariah Kite —; dumper. Length c. 47 cm. (18½ in.).

FIELD CHARACTERS. As of 658, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident in the heavy evergreen and moist-deciduous forests of the Western and Eastern Ghats and their associated hill ranges in peninsular India roughly south of Mahabaleshwar (c. 18°N.) in Maharashtra, Madhya Pradesh (Bastar dist.), Orissa (Russekonda), and south along the Eastern Ghats to the Shevaroy Hills and Kerala, and Ceylon. Also NE, India in Assam, Meghalaya, Nagaland and Manipur. Lowlands and up to c. 1800 m in the Nilgiris and Palnis, and 2100 m in Ceylon.

GENERAL HABITS. As in *newarensis* (658), q.v.

FOOD. Rodents, birds, reptiles, and reportedly fish.

VOICE and CALLS. A mellow, musical, hollow-sounding *tek...tek...tek* repeated every few seconds. The initial *tek* (sometimes twice) is a low undertone and audible only at close range. Birds particularly vocal during moonlight nights, and in the breeding season. Also utters a variety of weird, eerie shrieks and chuckles, in addition to the loud bill-snapping.

BREEDING. Season, January to March. Nest and eggs also as in 658. Average size of 9 eggs 49.9 × 44.1 mm. (Baker).

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit. Differs from the Himalayan race *newarensis* (658) in being much smaller, with the facial disc as a rule distinctly more ochreous or fulvous; supercilium less pure white; crown darker, nape paler. Birds from the Assam hills approach South Indian examples in colour, but are much larger.

Young (immature). Feathers with broad whitish edges, especially on crown and upper back. Wing-coverts pale dull rufous, barred with pale buff and broadly tipped with white. Underparts white at first, gradually assuming the barring.

OWLS

309

MEASUREMENTS

Wing	Bill (from cere)	Tarsus	Tail
♂ ♀ 291-360	c. 42	52-58	186-197 mm. (Various)

Bill from feathers 48-50 mm. (Baker)

COLOURS OF BARE PARTS. Iris brown ('rarely golden yellow' — Baker). Bill greenish horny, bluish near base; cere plumbeous. Feet pale leaden; claws dusky plumbeous.

MISCELLANEOUS. Was introduced in the Laccadive in the 1870s under a har-brained governmental plan for combating a plague of rats (*Rattus rufescens*). The grossly incompatible ecological conditions on these unforested coral islands, which the planners seem to have overlooked, soon brought an end to the birds but not to the rats! For an amusing account of this venture see Hume, SF 4: 433-4.

Athene brama
Spotted Owllet (650)

Athene blewitti,
Forest Spotted Owllet (653)

OWLS

311

dozing with eyes half closed, looking deceptively like a dead snag; often in a low bush or even on the ground in a shady ravine. Very parochial, pairs — presumably the same — occupying restricted territories and using the same nesting and roosting sites year after year if undisturbed.

FOOD. Rats and other small mammals, especially voles (*Alticola* spp.), birds (bulbul, blackbird), lizards, beetles, etc.

VOICE AND CALLS. A loud hoo . . . hoo . . . hoo-ho-ho-hoo, the final hoo being somewhat drawn out. There is a pause of about four seconds after the initial hoo, and half a second between the second and the rest of the concluding rolling note. 'The notes are not unlike those of the Turtle Dove' (Bates). Other calls sometimes heard are a loud quack, and a soft coo 'very similar to the call of the Ring Dove' (Osmaston). The calling begins an hour or so after sunset, generally from some exposed tree-top and is repeated often for 10 minutes at a time, a pair or number of birds calling and answering one another. When flying about at night a note repeatedly uttered sounding like *kha-wak*; occasionally also when perched (Magrath).

BREEDING. Season, apparently March to May probably varying somewhat with altitude. Nest, an unlined natural hollow in a tree-trunk, often quite low down and in close proximity to an occupied village hut (Kashmir). Sometimes in a recess or fissure under a large rock. Eggs, usually 2, rarely 3, white, roundish ovals. Average size of 5 eggs 50.6 × 43.3 mm. Share of the sexes in incubation, and incubation period, undetermined.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit. Tone of upper plumage paler and greyer than in *niricola*, without any rufous tinge; longitudinally streaked as well as barred v. barred only in 662.

MEASUREMENTS

Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀ 285-335	c. 33-35	50-51	191-210 mm (Baker)

Wing 6 ♂♂ 283-320; 6 ♀♀ 318-341 mm. *S. a. niricola* ♀♀ rarely exceed 310 mm. (Meinertzhagen, 1927, *Ibis*: 606).

COLOURS OF BARE PARTS. Iris dark brown. Bill greenish, yellow at tip; cere olive. Toes pale green; claws horny black, slaty at base.

662. Himalayan Wood Owl. *Strix aluco niricola* (Blyth)

Syrnium niriculum 'Hodgson' = Blyth, 1845, Jour. Asiat. Soc. Bengal 14 (1): 185 ('Himalaya', i.e. Nepal)

Upper plumage not streaked but barred only *S. a. niricola*

661. Scully's Wood Owl. *Strix aluco biddulphi* Scully

Strix biddulphi Scully, 1881, Ibis: 423, pl. 14 (Gilgit)-

Baker, FBI No. 1644, Vol. 4: 397

LOCAL NAMES. *Rātā mogūl*, *Rāt monglū* (Kashmir).

SIZE. Jungle Crow ±; dumpier. Length c. 47 cm. (c. 18½ in.).

FIELD CHARACTERS. A large brown owl with whitish facial disc and no ear-tufts.

Adult. Above, pale grey-brown streaked and barred with dark brown and mottled with whitish. Below, white; close-barred on chin and throat, streaked and narrowly barred on rest of underparts. Eyes dark brown; call diagnostic. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Resident, moving down from the highest levels in winter. Northern Baluchistan and northward along the Afghan border to Chitral, Gilgit, Baltistan, and Kashmir, between c. 1500 and 3800 m. occasionally nesting above tree line. Common in all wooded areas in Kashmir, in the main and side valleys. Partial to forests of oak, pine, and fir. Its status *vis-à-vis* *niricola* in the region of southern Kashmir and Himachal Pradesh unclear. Generally replaces *niricola* north of Simla and Mussooree.

Extralimital. Afghanistan.

GENERAL HABITS. Nocturnal, perhaps largely because of the merciless mobbing and chivvying it invariably suffers from crows, and other diurnal birds as soon as discovered in daytime. Spends the day standing upright and motionless on a branch close to the trunk, partially concealed by foliage,

312

STRIGIFORMES

Young (immature). Above, marked with narrow whitish, or fulvous, and broad dark brown bars; below, with equally broad bars of dull brown and pale or rich fulvous. Tail and wings as in adult.

STATUS, DISTRIBUTION AND HABITAT. Resident. The Himalayas between c. 1200 and 4250 m. altitude, from Murree in W. Pakistan eastward through Himachal Pradesh (race?), Garhwal, Kumaon, Nepal, Sikkim, Bhutan, and NEFA. Assam hills north and south of Brahmaputra river, Nagaland, Manipur, Mizo. Affects oak, pine, and fir forest.

Extralimital. Probably N. Burma. 'Shan States; China in provinces of Kansu, Szechuan, Yunnan, Hupeh, Kwangtung and Kweichow' (Peters).

GENERAL HABITS, FOOD. As in 661, q.v.

VOICE AND CALLS. As in 661, but two other calls described besides the normal treble hoot: a 'hurried deep low hu-hoo' (Whistler), and 'a note which could be produced by placing a blade of grass between the two thumbs and then blowing through these sharply' (? cf. *kharak* under 661). This possibly a nuptial call uttered (during courtship display?) 'usually on the wing as the bird soars up vertically for a few yards and descends for some distance with wings closed, gradually opening its wings and finally settling on the nearest suitable point of vantage' (P. T. L. Dodsworth, JBNHS 22: 627)

BREEDING. Season, mainly mid January to end April. Nest and eggs (2 or 3) as in 661. Average size of 13 eggs 48.2 × 41.6 mm. (Baker).

MUSEUM DIAGNOSIS. Similar to *biddulphi* (661) but very much darker above, the general tone being dark brown rather than pale grey. Dark markings on upperparts in the nature of bars only; no longitudinal streaks. Both barring and streaking on lower plumage bolder and darker. In the eastern part of its range, i.e. from about Nepal eastwards, has two distinct phases: one very rufous, the other greyish rufous.

MEASUREMENTS

Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀ 282-312	c. 22-24	c. 45-48	168-175 mm. (Baker)

1 ♂ 303 33 62 180 mm.
(Bhutan) (SA)

Weight 2 ♂♂ 375, 392, 1 ♀ 380 gm. (SA, GD). 1 ♀ 470 gm. (BB).

COLOURS OF BARE PARTS. Iris brown. Bill pale yellowish flesh; cere olive-brown. Tarsus woolly; toes partially feathered, plumbeous at ends; claws horny brown.

Genus ASIO Brisson

Asio Brisson, 1760, Orn. 1: 28. Type, by tautonymy, *Asio Brisson* = *Strix etas* Linnaeus

Aigrettes or ear-tufts present but varying in size. Bill short and strong, the part covered by the cere longer than rest of culmen. Facial disc well marked, nearly as high above the eyes as below; ruff complete or nearly so. Wing long and pointed: 2nd primary (as.) longest; 3rd nearly equal to it. Tail moderate and rounded. Tarsus and upper part of toes thickly feathered. Iris yellow.

Represented within our limits by two migratory Palearctic species.

Key to the Species

Transverse as well as longitudinal markings on abdomen.....*A. otus*
 No transverse markings on abdomen.....*A. flammeus*

663. Longeared Owl. *Asio otus otus* (Linnaeus)

Strix Otus Linnaeus, 1758, Syst. Nat., ed. 10, 1: 192 (Europa, restricted type locality = Sweden, ex Faun. Svec.)

Baker, FBI No. 1642, Vol. 4: 393

Plate 53, fig. 6

LOCAL NAMES. None recorded.

SIZE. Pigeon +; length c. 37 cm. (14½ in.).

FIELD CHARACTERS. A slim medium-sized owl, mottled grey-brown above, buff below, boldly streaked and barred with blackish. Two long, upstanding black-and-buff ear-tufts; yellow eyes. Sexes alike. When ears not prominent, may—on a good view—be distinguished from Shorteared Owl by heavily streaked v. plain unmarked-looking underparts.

STATUS, DISTRIBUTION and HABITAT. Within our limits recorded breeding once in Kashmir (Gurais—B. A. G. Shelley, 1895, JBNHS 10: 149) and once in N. Baluchistan (Quetta; A. F. P. Christison, MS., c. 1941). Mainly seasonal visitor to the northwestern parts—winter in the plains, summer (breeding?) at higher altitudes. Described variously as

vagrant, rare, and as locally not uncommon and even 'fairly plentiful' in some years: Sind, N. Baluchistan (Quetta dist.), Afghan frontier (Kohat dist.), Gilgit, Chitral, Kashmir, Baltistan, Himachal Pradesh (Chamba, Lahul); Punjab (Lahore, Rawalpindi (?), and Shahpur dists.), Delhi dist., Nepal, Gujarat (Kutch dist.); from plains level to c. 1800 m. alt. Affects semi-desert country—low jungle of stunted trees, poplar plantations, tall grass on waste land, etc. Bhutan (specimen. Biswas).

GENERAL HABITS. One of the most nocturnal owls, seldom seen except in the gathering dusk or at early dawn, or when flushed by chance. Usually keeps singly, but parties of 5 to 8 have been recorded (Punjab, Baluchistan) probably on migration passage. Roosts during daytime standing upright on a leafy branch close to the trunk with its plumage sleeked and body elongated or attenuated, making itself remarkably inconspicuous; thus doubtless often escaping observation. Sometimes rests on the ground under a bush or grass-tussock.

Extralimital. More or less throughout Europe and palaearctic Asia north to between c. 58° and 66°N. lat., and NW. Africa (see map).

FOOD. Rats, mice, and other small mammals; birds, lizards, beetles, etc. VOICE and CALLS. Not recorded in India. Elsewhere 'the most characteristic note is the "song", a long drawn, low *ōō. ōō. ōō* . . . , a cooing moan

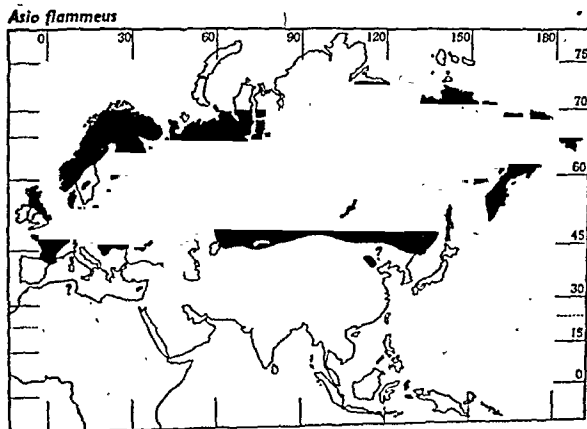

× c. ½

SIZE. Pigeon +; length c. 38 cm. (15 in.).

FIELD CHARACTERS. A slim medium-sized owl, overall pale buff, heavily streaked with dark brown, and with a darker greyish head. Facial disc white with bristly black feathers intermixed, surrounded by a dark brown ruff. Two short blackish brown upstanding ear-tufts above the yellow eyes. Wings and tail barred rufous and black. Below, pale buff, longitudinally brown-streaked on breast. Sexes alike.

In flight the rufous on the upperside and the white underside of the pointed wings with a prominent dark bar across each, and blackish tips, are leading pointers to its identity.

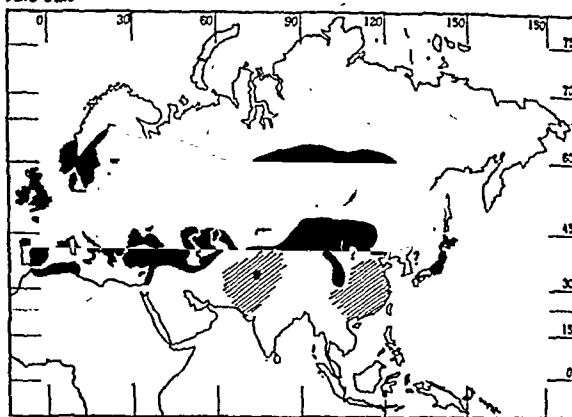

STATUS, DISTRIBUTION and HABITAT. Winter visitor (September/October to March/April) and/or passage migrant (the latter chiefly in northern mountainous portions, e.g. Gilgit, NW. Afghan frontier region). Practically throughout the subcontinent including both Pakistans, the entire Indian Union together with Nepal, Sikkim, Bhutan (?) to eastern Assam and Manipur. Also occasionally to Ceylon and Maldives Is. Not recorded in the

■ Palaearctic breeding range

Andamans or Nicobars. Plains and hills, normally to c. 1400 m., in appropriate facies. Local occurrences irregular, and abundance variable year to year; occasionally 'invasions'. Affects open, undulating grassy country

Asio otus

■ Breeding range ■ Winter

rather than a hoot, with the notes spaced at regular intervals of about one every third second, and audible as much as half a mile' (C. B. Moffat in Witherby, where some other notes also described).

BREEDING. Season in Europe mid March to early May. Of the two cases authenticated within our limits the first nest with 4 highly incubated eggs was found on 4 June 1895 (above Gurais, Kashmir), the second in Galbraith Spinney, Quetta (date not mentioned). Nest, in the first case a dilapidated nest, probably crow's, c. 4 m. up in a sycamore tree; in the second case an old magpie's nest was used. Eggs, elsewhere usually 4 or 5, broad white ovals, slightly glossy. Average size of 100 British eggs 40.94 × 32.7 mm. (Witherby).

MUSEUM DIAGNOSIS. For description of plumages and structure (also bionomics), see Witherby, 1938, 2: 327-31.

MEASUREMENTS

	Wing	Tarsus	Tail
♂ ♀	285-305*	c. 40	140-155 mm.

*Rarely as small as 280 mm. or as large as 310 mm.

(Hartert)

*Culmen c. 28-29 mm.; cere c. 6-8 mm. (Baker).

Weight 1 ♀ 8.75 oz. (c. 250 gm.).—Biddulph. 1 ♀ 290 gm.—BB.

COLOURS OF BARE PARTS. Iris bright golden orange. Bill blackish horn, greyish flesh at tip. Claws blackish horn (Witherby).

664. Shorteared Owl. *Asio flammeus flammeus* (Pontoppidan)

Strix Flammea Pontoppidan, 1763, Dansk. Atlas 1: 617, pl. 25 (Sweden)

Baker, FBI No. 1643, Vol. 4: 394

Plate 53, fig. 7

LOCAL NAMES. *Pūcha mūnga* (Malayalam); *Bassā* (Sinhala); *Āndai* (Tamil); *Būkhāomnu* (Maldivian).

dotted with bushes, sparsely scrubbed hillsides, tall grassland on the margin of jheels; also in semi-desert.

Extralimital. Breeds in Europe and Asia north to c. 70°N. lat., south to Italy, the Balkan Peninsula, Caucasus, Turkestan, N. Mongolia, SE. Manchuria, and Sakhalin I. Also in N. America. In the Old World winters south to the Mediterranean, N. Africa, Palestine, Ethiopia and Aden, besides India. (For details of range see Vaurie, 1965: 595-6.)

GENERAL HABITS. In winter met with singly, in loose parties of 5 or 6, or scattered flocks ('swarms') of 20 or more birds. Very diurnal and terrestrial; frequently put up in scrubby grassland while walking up quail or partridge, or seen flying about and hunting in broad sunshine—hawking insects. Often flushed from the ground in daytime while at rest, standing upright at the base of a diminutive bush practically in the open, or sunning itself sprawled belly to ground with the wings outspread. Flies with leisurely-looking deliberate full wing-strokes, rather reminiscent of a Houbara bustard from the rear. But flight irregular, rather rolling and wandering, punctuated with glides. Either flops into the herbage again after a hundred metres or so or covers long distances before alighting, sometimes rising very high up in the air and flying in wide circles, especially when mobbed by crows and other birds. Has been observed miles out at sea between Kutch and Bombay coming from the west flying eastward towards land, evidently on migration (from ?), at times flying high above the observer's ship, at others skimming the water's surface like a gull (McCann, JBNHS 38: 624).

FOOD. Field rats and mice, small birds, grasshoppers, locusts, beetles, etc.

VOICE and CALLS. Very silent in its winter quarters; no calls recorded in India.

BREEDING. Extralimital.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.; for plumages and structure (also bionomics), Witherby, 1938, 2: 334-5.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	290-325	29-31	43-48	139-150 mm. (SA, HW)

The sexes do not differ appreciably in size.

COLOURS OF BARE PARTS. Iris bright lemon-yellow. Bill slaty black; mouth lined pink. Toes (exposed portion) dark brown; soles dirty pale flesh colour; claws horny black.

Genus *AEOLIS* Kaup

Argolius Kaup, 1829, Skizz. Entw.-Gesch. Eur. Thierw.: 34. Type, by monotypy, *Strix tenguismi* Gmelin = *Strix fuscus* Linnaeus, 1758

Contains small owls with large rounded head; no ear-tufts but faint indications of them. 4th and 5th primaries (as.) equal and longest. Two outermost visible primaries only notched (emarginated) on inner webs, and rather near to tip. Tail slightly rounded. Tarsus and toes very thickly clothed in feathers.

Genus northern Holarctic.

Not in Baker, FBI Plate 54, fig. 9

LOCAL NAMES. None recorded.

SIZE. Spotted Owlet +; length c. 25 cm. (10 in.).

FIELD CHARACTERS. More or less like Spotted Owlet (650) but larger, chocolate-brown, and with a wide and distinct facial disc. Legs and feet thickly feathered to tips of toes. See figure, p. 256.

x c. 1

STATUS, DISTRIBUTION and HABITAT. Species previously unknown within Indian limits. A single breeding female together with a feathered juvenile collected at Kyzylang (32°33'N., 77°03'E.) in Lahul dist. of Himachal Pradesh.

Extralimital. Europe and C. Asia south to the Himalayas.

MUSEUM DIAGNOSIS. For description of plumages and structure (also bionomics) see Witherby, 1938, 2: 320-2.

MEASUREMENTS

	Wing	Bill (from base of feathers)	Tarsus	Tail
♂ ♂	160-170	18-21	20-23	95-106 mm.
♀ ♀	165-180	—	—	—

(Witherby)

More specimens of Tengmalm's owl from the NW. Himalayas are needed to settle the status of the population here.

COLOURS OF BARE PARTS. Iris yellow. Bill yellow. Claws brownish black (Witherby).

APPENDIX

p. 29

452a. Great Blackbacked Gull. *Larus marinus* Linnacus

Larus marinus Linnacus, 1758, Syst. Nat., ed. 10, 1: 136 (Gotland, Sweden)

SIZE. Same as 453.

FIELD CHARACTERS. A dark-mantled maritime gull, distinguished from Lesser Blackback (452) chiefly by larger size and pale pink or greyish pink

APPENDIX

319

Hodgson's Hawk-Cuckoo (575)	Sibilant, insistent <i>gee-whizz</i> repeated up to 20 times. Rather like 572 but shriller and thinner.
Brainfever Bird (573, 574)	Loud, shrieking, high-pitched <i>wee-pitchit</i> or <i>brain-fever</i> in crescendo runs of 4-6 broken off abruptly. Repeated endlessly.
Indian Cuckoo (576)	Loud, far-carrying 4-syllabled flutey whistles <i>bo-kotko</i> or <i>orange-pekeo</i> or <i>crossword puzzle</i> repeated endlessly.
Cuckoo (577, 578, 579)	The well-known <i>cick-ko</i> repeated persistently in long unbroken runs.
Himalayan Cuckoo (580)	Loud, far-carrying (<i>tip</i>) <i>-oep-oep-oep-oep</i> , very like hoopoe's but 4-noted instead of 3.
Small Cuckoo (581)	Unmusical chattering cry of 5 or 6 notes <i>that's your choky pepper</i> ... <i>choky pepper</i> (accent on first <i>choky</i>). Quickly repeated.

Order CAPRIMULGIFORMES

For morphological details etc. see Stresemann, E., 1927-34, *Aves*: 826-8.

Family PODARGIDAE: Frogmouths

Bill very wide at gape as in Nightjars but much larger; powerful, hard, curved, hooked at tip. Base of bill overhung by bristly feathers concealing the nostrils, which are narrow slits protected by membranes. For further details see Van Tyne, J. & Berger, A. J., 1959: 461; Serventy, D. L., 1964, Article 'Frogmouth' in Thomson, A. L. (ed.), *New Dict. Birds*, London & New York.

Genus BATRACHOSTOMUS Gould

Batrachostomus Gould, 1838, *Icones Avium*, pt. 2, pl. (17) and text.

Type, by monotypy, *Podargus auritus* J. E. Gray

Gape even wider than in Nightjars, with the corners swollen and enlarged. Nostrils concealed by conspicuous bristles projecting from the feathers at base of bill; tufts of similar feathers in front of the eyes, and ear-tufts. Wings rounded and short: 4th and 5th primaries (as.) subequal and longest, occasionally the 5th. Tarsus short; feet small and feeble with middle toe greatly elongated. No oil gland; a powder-down patch on either side of rump. Sexes dimorphic in coloration.

Genus Oriental and Australasian; represented in our area by two species with the same remarkable widely discontinuous Indo-Malayan distribution as e.g. the Lizard Hawks (*Aviceda*) cf. Ind. Hb. 1: 215, 218.

Key to the Species

Scapulars with broad white patches; no white spots on wing-coverts *B. hodgsoni*
Scapulars without any white; round white spots on wing-coverts *B. moniliger*

666. Ceylon Frogmouth. *Batrachostomus moniliger* Blyth

Batrachostomus moniliger 'Layard' = Blyth, 1846, *Jour. Asiat. Soc. Bengal* 18: 806 (Ceylon)

Baker, FBI No. 1635, Vol. 4: 381

Plate 55, fig. 1

LOCAL NAMES. *Gembi-kata-bassā* (Sinhala); *Makkāchikkāta* (Malayalam).

SIZE. Myna \pm ; length c. 23 cm (9 in.).

FIELD CHARACTERS. An obliteratively coloured nightjar-like bird with absurdly wide gape and broad, swollen, horny bill aptly suggestive of the name Frogmouth, and completely diagnostic.

Male (adult) grey-brown, vermiculated and mottled with white, buff, brown, black, and chestnut.

1

1

FROGMOUTHS

3

resembling the screech of a fishing reel running out fairly slowly' (Henry).

BREEDING. Season, apparently straggling, chiefly January to April; in Ceylon also September. Nest, a small pad, c. 6 cm in diameter, of moss, leaves, and twigs felted with down from the bird's underplumage, and camouflaged on the outside with bits of lichen and bark. Placed in the fork of a small tree or on a horizontal branch c. 2 to 5 metres off the ground. Egg, a singleton, large for the size of the layer, white, elliptical, fine-textured. Average size of 30 eggs 29.9 × 20.6 mm (Baker). Both sexes share in incubation, the male chiefly sitting during daytime. Period of incubation and other facets of breeding biology unknown.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit. Tarsus fully feathered in male; c. two-thirds in female.

Nestling covered with pure white down (T. R. Bell).

MEASUREMENTS

	Wing	Bill (from skull)	Tail
♂ ♀	119-127	21-23	100-110 mm (HW, SA)

Tarsus c. 15; width of gape 32-34 mm (Baker).

COLOURS OF BARE PARTS. Iris pale khaki or brownish buff ('yellow, or marbled yellow and grey'—Baker). Bill pale horny, yellowish at gape and chin; mouth sulphur yellow; gullet pink. Feet dusky yellow; claws brownish.

667. Hodgson's Frogmouth. *Batrachostomus hodgsoni hodgsoni* (G. R. Gray)

Otothrix hodgsoni G. R. Gray, 1859, *Proc. Zool. Soc. London*: 101, pl. 152, *Aves* (Northern India = Darjeeling)

Batrachostomus hodgsoni rupchandi Koelz, 1954, *Contrib. Inst. Regional Exploration*, No. 1: 27 (Karong, Manipur)
Baker, FBI No. 1633, Vol. 4: 378

Plate 55, fig. 2

LOCAL NAME. *Sūmbong* (Manipur Naga).

SIZE. Myna +; length c. 27 cm (10½ in.).

FIELD CHARACTERS. As for 666, q.v. See Key.

Young (immature). Like adult female but duller blackish brown; signs of the collar show very early. Iris dull brown; bill horny grey, pinkish above (Baker).

STATUS, DISTRIBUTION and HABITAT. Resident. Apparently rare. Sikkim (from extreme eastern Nepal?),

Bhutan, Assam hills north and south of Brahmaputra river, Nagaland, Manipur, Mirzo(?), East Pakistan (Tippera and Chittagong Hill Tracts), between c. 300 and 1800 m. Affects sub-tropical evergreen forest.

Extralimital. Hill of N. Burma (Chin, Kachin, etc.).

Head, ♂ x 1

2

CAPRIMULGIFORMES

Female dull rufous overall; upper wing-coverts boldly spotted with black-edged white spots.

Young (immature). Narrowly barred above with brown.

STATUS, DISTRIBUTION and HABITAT. Resident. Apparently rare. The southern heavy-rainfall tracts of the Western Ghats from c. 15°N. lat. in N. Kanāra dist. (Mysore) south to Trivandrum dist. (Kerala) up to c. 1200 m; Ceylon, throughout the forest areas up to c. 1800 m. Affects dense evergreen forest and secondary jungle with cane brakes etc.

Batrachostomus

Known distribution 1 *B. moniliger* (666). 2 *B. h. hodgsoni* (667).

GENERAL HABITS. Little known. Nocturnal; seldom seen in daytime unless flushed by chance. Spends the day in dense jungle perched across a branch (like a passerine bird) body tilted at a slight angle with the tail pointing downward, simulating a broken stump. On alarm stretches neck and head upwards, bill and rictal bristles pointing to sky, eyes closed to slits, thereby heightening its resemblance to a lichen-covered snag. Eludes detection further by remaining completely immobile even on very close approach by observer, while following his movements by almost imperceptibly screwing the head round as in an owl. Wide gape and surrounding bristles suggest adaptation for hawking winged insects, but reported to take them chiefly on the ground or from branches.

FOOD. Moths, beetles, grasshoppers, etc.

VOICE and CALLS. Uncertain. Circumstantially described as commencing considerably after dark and variously as 'a soft, rapid *kooroo, kooroo, kooroo*' (Butler), 'a series of 10-15 low but rather rapid *whoo, whoo, whoo, whoo* notes' (Phillips), 'a fairly loud liquid chuckle *ahwoo* repeated monotonously every 2 or 3 seconds for 30 minutes or more at a stretch' (Sālim Ali). 'A bird which was kept under observation by C. E. Norris uttered a call

4

CAPRIMULGIFORMES

GENERAL HABITS, FOOD, VOICE and CALLS. More or less as in 666, but imperfectly known.

BREEDING. Season, April to July. Nest and site, as in 666. Eggs, normally 2 sometimes a singleton, white, elliptical. Average size of 30 eggs 26.5 × 17.6 mm (Baker). Both sexes incubate, the male mostly during daytime. According to Baker both birds assist in making the nest, pulling the down from their lower plumage and welding it into the branch and then into the nest itself.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

Nestling covered with bright rufous down.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	126-141	17-18 width at gape 29-32	c. 15-16	131-143 mm (Baker)

COLOURS OF BARE PARTS. Iris variegated grey, brown and yellow. Bill fleshy pink or yellowish horn. Feet pinkish flesh.

Family CAPRIMULGIDAE: Nightjars or Goatsuckers

For morphological details etc. see Stresemann, E., 1927-34, *Aves*: 827; Witherby et al., 1938, 2: 251; Baker, 1927, 4: 358; Junge, G. C. A., 1964, Article 'Nightjar' in Thomson, A. L. (ed.), *New Dict. Birds*, London & New York.

Bill short, weak, flexible and with an enormous gape. Nostrils tubular. Wing long: 2nd primary (as.) generally longest. Family represented throughout the tropical and temperate regions of the world.

Wing over 290 mm	<i>E. m. cerniceps</i>
Wing under 290 mm	<i>E. m. bowdlerii</i>

NIGHTJARS

5

668. *Eurostopodus macrotis cerviniceps* (Gould)

Lyncornis cerviniceps Gould, 1838, *Icones Avium*, (2), pl. 14 and text ('Said to be a native of China or the adjacent islands' = Trang, Peninsular Siam by designation of Robinson & Kloss, 1923, *Jour. Nat. Hist. Soc. Siam* 5: 140) Baker, FBI No. 1631, Vol. 4: 374

LOCAL NAME. *Din koo nah* (Assam).

SIZE. House Crow —; length c. 41 cm (16 in.).

FIELD CHARACTERS. A very large and handsome dark coloured nightjar with the characteristic mottled and vermiculated plumage of the family — grey, black, buff, and chestnut. Two prominent erectile ear-tufts on sides of head behind the eyes, and distinctive whistling call diagnostic. Sexes alike.

In overhead flight large size, long tail, and stately wing-beats particularly striking.

STATUS, DISTRIBUTION and HABITAT. Resident. Possibly local migrant in some areas: thus in NE. Cachar 'appears about beginning of August; very plentiful in August and September; disappears at the end of the rains' (James Inglis, 1877, SF 5: 17). Assam east and south of Brahmaputra river, Nagaland, Manipur, Mizo, East Pakistan (Tippera and Chittagong Hill Tracts). Affects evergreen and moist-deciduous biotope, from plains level to c. 1000 m alt.; commonest in foothills country.

EXTRALIMITAL. Southern Yunnan south through Burma and Malay Peninsula and Penang; SE. Thailand, South Vietnam.

GENERAL HABITS. Crepuscular and nocturnal. Roosts during daytime squatting belly to ground, or on a fallen log amongst scrubby undergrowth in a ravine; also in caves (Tenasserim, Burma). Issues forth at sundown heralded by the distinctive clear whistling calls, circling high above the forest tree-tops with the leisurely deliberate wing-beats of an owl. Descends lower as the dusk deepens, sailing swiftly a metre or two above ground on motionless wings like a harrier to hawk winged insects in a forest clearing; sometimes a loose party of 7 or 8 birds criss-crossing one another at different levels in the air.

FOOD. Moths, bugs, beetles, flying termites, and other insects captured on the wing.

VOICE and CALLS. In general pattern similar to 669 of Kerala; described by A. F. P. Christison as 'Pee-whoeeoo-whoeeoo-whoeeoo repeated a variable number of times, followed by a protracted quavering whistle ending in a cadence'. Uttered chiefly on the wing; sometimes repeated for several minutes while squatted on a tree-stump like a nightjar, the head shot forward with a jerk at each call.

BREEDING. Season, mainly January to April as far as known. Nest, none built. Egg, a singleton laid on the bare ground in thin forest or bamboo jungle under shelter of a bamboo clump or thick bush. Broad to long ellipse in shape, typical of the nightjars, pale yellowish cream to deepish rosy salmon (when fresh), variably marbled with pale grey and occasionally pale bright reddish. Average size of 6 eggs 42.1 × 30.5 mm (Baker). Share of the sexes in the domestic chores, and incubation period, unknown.

NIGHTJARS

7

MUSEUM DIAGNOSIS. Doubtfully distinguishable from 668 except by smaller size. Perhaps a little darker with less buff and more grey on the wings and upper-parts.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
		(from skull)		
♂ ♀	274-285	20-22	c. 21	162-203 mm (HW, SA, Baker)

COLOURS OF BARE PARTS. Iris brown. Bill pinkish brown, nostrils and tips of both mandibles blackish brown. Legs pale pink; toes dusky; claws horny brown.

NOTE. Possibly some form of *Eurostopodus* occurs in the Andaman group of islands. It is claimed to have been seen on Southern Jolly Boy Island by a party including two competent and dependable observers, Dr Stoliczka and Mr Ball (Hume, 1874, SF 2: 162), but no specimen was collected, nor has been since.

Genus CAPRIMULGUS Linnaeus

Caprimulgus Linnaeus, 1758, *Syst. Nat.*, ed. 10, 1: 193. Type, by tautonymy,

Caprimulgus europaeus Linnaeus

Wing long and pointed: 2nd primary (as.) longest, 1st and 3rd slightly shorter. Tail long, graduated. Rectal bristles strong and numerous, generally white at base. Tarsus feathered in some species, naked in others. Sexes alike except that in some species the white patches in the wings and tail of the male are buff or rufous in the female.

Nightjars are soft-plumaged, long-winged, crepuscular and nocturnal birds with longish tails, very short legs and short soft bills with enormous gapes. Plumage overall mottled, vermiculated, barred and streaked with brownish buff, grey, rufous, black and white, blended in a remarkably obliterative or camouflaging pattern. The different species are usually difficult to identify in the field except by their calls chiefly heard in the breeding season, which are distinctive and specifically diagnostic. See Key to the Calls.

CAPRIMULGIFORMES

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
		(from feathers)		
♂ ♀	292-317	c. 10-11	21-22	207-225 mm (Baker)

COLOURS OF BARE PARTS. Iris hazel to dark brown. Bill pale pinkish horny to pinkish brown, tip and culmen darker; gape flesh-coloured. Legs and feet fleshy brown to pale brown.

669. *Eurostopodus macrotis bourdilloni* (Hume)

Lyncornis Bourdilloni Anonymous = Hume, 1875, *Stray Feathers* 3: 302 (Kalland, Khauni, Travancore) Baker, FBI No. 1632, Vol. 4: 375 Plate 55, fig. 10

LOCAL NAME. *Sāndhī māzhākki* (Malayalam).

SIZE. House Crow —; length c. 40 cm (15½ in.).

FIELD CHARACTERS. As of 668, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Range curiously discontinuous and restricted [cf. *Batrachostomus moniliger* (666)] but absent in Ceylon. Known only from Kerala (Kottayam, Quilon, and Trivandrum dists.) and Goa (Valpoi?, JBNHS 73: 45). Sedentary and local; not uncommon where occurring.

Confining to evergreen and moist deciduous biotope, chiefly foothills jungle and up to c. 1000 metres.

GENERAL HABITS and FOOD. As in 668, q.v.

VOICE and CALLS. A beautiful loud, clear, rather supercilious-sounding ('wailing') double- or 3-noted whistle, *whi-whoeeew* uttered chiefly on the wing — the first syllable short and abrupt, the second very long and drawn-out. A third short undertone note preceding the call is often audible at close range. Heard mostly during the short interval between sunset and dark, and then again in a brief burst at earliest dawn before the birds retire for the day. Silent at night except for sporadic calls during moonlight. Several birds answer one another from different directions.

BREEDING. Season, January to May, chiefly February and March. No nest. Egg, a singleton, laid on the bare ground on a bush-covered broken hillside or in thin undergrowth in forest. The same site is said to be occupied year after year. Eggs very variable in colour and markings — from unmarked rich salmon-cream to the same blotched and speckled with chestnut; or cream, densely marbled with brown at one end and clouded with grey elsewhere. Average size of 40 eggs 40.0 × 28.8 mm (Baker).

CAPRIMULGUS INDICUS Latham: INDIAN JUNGLE NIGHTJAR

Key to the Subspecies

- A Upperparts paler; wing c. 172 to 198 mm..... *C. i. indicus*
- B Upperparts darker 1
- 1 Smaller; wing c. 167 to 184 mm..... *C. i. kelaarti*
- Larger; wing c. 196 to 219 mm
- a More rufous, less grey *C. i. hazarae*
- b More grey, less rufous *C. i. jotaka*

670. *Caprimulgus indicus hazarae* Whistler & Kinnear

Caprimulgus indicus hazarae Whistler & Kinnear, 1935, *Jour. Bombay nat. Hist. Soc.* 38: 37 (Abbotabad, Hazara, Himalayas)

Caprimulgus indicus menziesi Koelz, 1954, *Contrib. Inst. Regional Exploration*, No. 1: 27 (Blue Mountain, Lushai Hills) Baker, FBI No. 1626 (part), Vol. 4: 367

LOCAL NAMES. *Chhippik*, *Chhāppī*, *Dābchiri*, *Dābnak* (for all nightjars — Hindi); *Tamor* (Lepcha); *Wahatshai* (all nightjars — Naga); *Deo chuk* (Cachari).

SIZE. Pigeon —; length c. 32 cm (12½ in.).

FIELD CHARACTERS. As for the Genus, q.v. Call diagnostic, see below; also keys to the Species and Subspecies, and Museum Diagnosis.

Female similar to male but tail-feathers mottled throughout and without the white tips. No white spots on primaries; these more or less indicated by smaller rufous spots or patches.

NIGHTJARS

9

STATUS, DISTRIBUTION and HABITAT. Resident, local and altitudinal migrant. The entire Himalayas from Hazara dist. in NW. Pakistan eastward to NEFA (including Nepal, Sikkim, Bhutan). Assam hills north and south of Brahmaputra river, Nagaland, Manipur, Mizo, and East Pakistan; from the foothills to c. 3300 metres. Affects forest glades, and sparsely scrubbed ravines and hillsides contiguous with jungle.

Extralimital. Yunnan, Burma, Malay Peninsula — Peters.

GENERAL HABITS. Insectivorous, crepuscular, and nocturnal. Roosts in some shady spot during daytime squatted lengthwise on a bough, or on the ground among dry leaves and stones where its coloration obliterates it in an astonishing way. Emerges soon after sunset to hawk winged insects, flying about and sailing erratically above the forest or close to the ground in glades and clearings, performing agile aerial contortions in pursuit of prey. Is fond of squatting in the middle of cross-country earth tracks after dusk, its eyes gleaming ruby in the headlights of an oncoming car, and is adept at dodging clear by flip-flap zigzags when within an ace of being run over. Flight completely silent as in the likewise soft-plumaged owls except for an occasional smack of the wing-tips during the lightning twists and turns. In spite of the very short legs, occasionally runs for short distances, e.g. at the nest site, with a shuffling, waddling gait, often with the wings raised almost vertically back to back.

FOOD. Moths, bugs, beetles, and other winged insects captured in the air.

VOICE and CALLS. Calling commences as soon as dusk deepens to darkness and, with short breaks, is sustained more or less continuously through the night, ceasing only at dawn. Particularly vocal during moonlight nights in the breeding season. Call normally of two types: (1) a quick-repeated *chuck* (or *tuck*)-*chuck-chuck* (at c. 5 *chucks* in 2 seconds) in unbroken runs of 50 or more, (2) a less rapid *chuckoo-chuckoo-chuckoo* in runs of 3 to 14 (at the rate of about 3 in 2 seconds), the runs repeated monotonously again and again for 3 to 5 minutes at a stretch with an occasional miss of a beat or a pause of a second or two. The *chuckoo* calls sometimes end in a pleasant hollow-sounding *wowowowowowow* fading off in a series of 'intake' whistles reminiscent of an oil-engine conking out. This, according to one observer (A. E. Jones), is while the calling male is chasing another bird, 'probably its mate'.

A third call, *ik-krükroo*, common in the nominate peninsular race (671, q.v.), has curiously enough not been recorded in the Himalayan bird.

BREEDING. Season, March to June, principally April and May. No nest. Eggs, 2, white, marbled with primary markings of dark grey or greyish brown, and secondary markings of pale grey; quite different from those of the two other races of *indicus*! Average size of 100 eggs 30.7 × 22.7 mm (Baker). Both sexes share incubation; incubation period *vide* Baker 16 to 17 days.

MUSEUM DIAGNOSIS. See Key to the Species; for details of plumage, Baker loc. cit. Separable from the nominate race (671), in a series, by the general tone of coloration being warmer and browner (less grey); markings on the back heavier; barring on the tail broader. Also, individuals tend to average larger in size.

NIGHTJARS

- 11

GENERAL HABITS and FOOD. As in 670, q.v.

VOICE and CALLS. In addition to the two calls described under 670, peninsular birds commonly have a third call—a pleasant though rather mournful *ik-krükroo*, monotonously repeated every two seconds or so, in unbroken runs of a quarter or half hour. It is resumed after a short pause, and continued thus more or less throughout the night, particularly in moonlight. Either the first two calls or the third are uttered at a time (by same or different individuals?); we have not heard one type of call being switched over to the other while a bird is calling. The significance of this alternative call in peninsular birds is not understood. In moonlight, in breeding season, calls all night in long unbroken runs — *chuck-chuck-chuck-chuck* etc. — at about two *chucks* per second, sounding in the distance singularly like the oil engine of a village flour mill.

BREEDING. Season, February to May, chiefly March and April. No nest. Eggs, 2, very similar to those of *C. m. atripennis* (676) and different from those of the Himalayan race; pale creamy to warm buff, spattered irregularly all over with blackish- or reddish brown spots. Laid on the bare ground on a stony hill slope, or in a ravine, sometimes but not always in the shade of a bush. Average size of 38 eggs 30.4 × 21.3 mm (Baker). Both sexes incubate; incubation period undetermined, presumably as in the Himalayan race (670) — 16 or 17 days.

MUSEUM DIAGNOSIS. See Key to the Species. Compared with *C. i. hazarae*, this race is greyer on the upperparts, more finely streaked on the back, and more narrowly barred on the tail. Juveniles are very different-looking, with much warm brick-rufous suffusion in the plumage.

MEASUREMENTS	Wing	Bill (from skull)	Tarsus	Tail
♂♂	174-198	20-24	15-18	125-144 mm
♀♀	181-195	20-24	15-18	124-135 mm (SA, HW)

COLOURS OF BARE PARTS. Iris brown; fine circumorbital rim yellow. Bill horny brown, yellowish on commissure and gape. Feet pinkish brown; claws pale horny brown.

672. *Caprimulgus indicus kelaarti* Blyth

Caprimulgus kelaarti Blyth, 1852 (1851), Jour. Asiat. Soc. Bengal 20: 175 (Ceylon)
Baker, FBI No. 1627, Vol. 4: 368

LOCAL NAMES. *Bin bari* (Sinhala); *Pādukāi kūrāi* (Tamil).

SIZE. Myna +; length c. 27 cm (10½ in.).

FIELD CHARACTERS. As for the Genus, q.v. See keys to the Species and Subspecies, and Museum Diagnosis.

Female differs from male as in 670.

STATUS, DISTRIBUTION and HABITAT. Race peculiar to Ceylon. Resident in the Hill Zone; locally distributed throughout the hills to over 6000 ft [c. 1800 m]. More common on the eastern or Uva aspects where the climate is drier (Phillips).

10

CAPRIMULGIFORMES

MEASUREMENTS

	Wing	Tail
♂♂	200-215	124-146 mm
♀♀	187-203	126-137 mm (HW, BB, SA)

COLOURS OF BARE PARTS. Iris deep brown. Bill pinkish brown, paler at base and gape. Feet fleshy brown.

671. *Caprimulgus indicus indicus* Latham

Caprimulgus indicus Latham, 1790, Index Orn. 2: 588 (India)
Baker, FBI No. 1625, Vol. 4: 366

Plate 55, fig. 6

LOCAL NAMES. Same as for 670 where applicable. *Kūpoo* (Adivasi Bhillā); *Et chukoo* (Malayalam); *Dibātā birdhani* (= God's carpenter—Oriya).

SIZE. Pigeon —; length c. 29 cm (11½ in.).

FIELD CHARACTERS. As for the Genus, q.v. See keys to the Species and Subspecies, and Museum Diagnosis.

Female differs from male as in 670.

STATUS, DISTRIBUTION and HABITAT. Resident and partial local migrant. Practically all India south of the Himalayas including Kerala. Absent in W. Rajasthan, Kutch, and sub-Himalayan W. Pakistan. Affects open scrub, and dry- and moist-deciduous jungle; from plains level up to c. 2300 m in the peninsular and S. Indian hills. Teak plantations and mixed bamboo forest are favourite haunts.

Caprimulgus indicus

	<i>C. i. hazarae</i> (670).		<i>C. i. indicus</i> (671).
	<i>C. i. kelaarti</i> (672).		<i>C. i. jolaka</i> (RE).

12

CAPRIMULGIFORMES

GENERAL HABITS and FOOD. As in 670, q.v.

VOICE and CALLS. Song described as far-carrying and reminiscent 'of the exhaust note of a small gas engine *chuk'm chuk'm chuk'm chuk'm*... repeated for many minutes at a time during the courting season. At close quarters this song has a curious resonant quality, the *chuk* being superimposed, as it were, upon a throbbing drone represented by the *m*. The courting male has also another note which sounds like *hōō hōō hōō hōōleter hōōleter*... uttered in flight with wings held high and steady, and tail widely expanded and canted to one side or the other, exposing the white tips of the four outer feathers' (Henry). Cf. *wowowowowowow* under 670.

BREEDING. Season, February/March to June/July. Eggs, 2, smaller replicas of those of the Indian bird (671); also laid without nest on bare stony ground in similar sites. Average size of 12 eggs 26.1 × 20.7 mm (Baker).

MUSEUM DIAGNOSIS. See Key to the Species. Smaller than the nominate race (671) with the tail perhaps darker and more heavily barred.

MEASUREMENTS	Wing	Tail
2 ♂♂	174-180	126 mm
1 ♀	174	116 mm (HW)

Weight 1 ♂ 69 g (SDR).

COLOURS OF BARE PARTS. As in 671.

672a. *Caprimulgus indicus jolaka* Temminck & Schlegel
(See Appendix, p. 257)

673. Hume's European Nightjar. *Caprimulgus europaeus uncinus* Hume
Caprimulgus uncinus Hume, 1871, Ibis: 406 (Agrora Valley and in the neighbourhood of Abbottabad. The specimens listed as types in the Cat. Bds. Brit. Mus. are from the former locality)

Baker, FBI No. 1619, Vol. 4: 359

Plate 55, fig. 4

LOCAL NAMES for all nightjars: *Chhippāk*, *Chhippā* (Hindi); *Chapāki* (Punjab Salt Range); *Patāk* (Rawalpindi dist.).

SIZE. Myna +; length c. 25 cm (10 in.).

FIELD CHARACTERS. As for the Genus, q.v. A small greyish brown nightjar. See keys to the Species and Calls, and Museum Diagnosis.

Female similar to male but with no white on the tail; the white wing-bar is replaced by buff, sometimes whitish in centre sometimes profusely marked with dark brown.

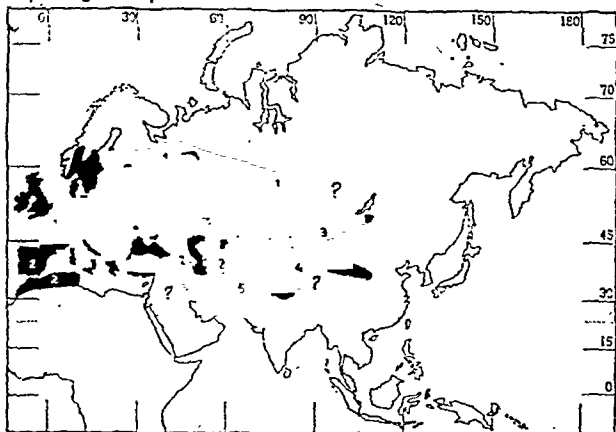

STATUS, DISTRIBUTION and HABITAT. Summer visitor and passage migrant (April/May to August/September) to West Pakistan, breeding in the lower hills and valleys of the mountain ranges, between c. 1600 and 2800 m, in C. and N. Baluchistan (Kalat, Quetta, Ziarat, Chaman, etc.) and in the Afghan frontier areas (Peshawar and Rawalpindi dists., Kurram Valley, Thal, etc.) north to Gilgit. Probably also in Kashmir, but no breeding record east of Murree. Obtained at Skardu, Baltistan by Meinertzhagen in August (status?). Fairly common and abundant as a transient on autumn passage (c. September) in southern Makran, Sind, and Kutch which lie on the easternmost fringe of the known migration route from Afghanistan.

NIGHTJARS

13

NW. Pakistan, etc. over Arabia to its winter quarters in Africa. The bulk evidently by-passes these areas on northward passage in spring (c. April) since the bird is rare in Sind at that season, and apparently absent in Kutch. Stragglers have been recorded in Jodhpur (Rajasthan) and Bombay City in October, and as far east as Gorakhpur in Uttar Pradesh (c. 83°E.) in January. Affects sparsely forested and open hillsides with *Dodonaea*, *Gymnosporia* and suchlike bushes.

Caprimulgus europaeus

■ Breeding range
 1, 2, 3, 4 extralimital races.

Extralimital. Breeds also from the eastern shores of the Caspian Sea east to Kuldja and the Khangai Mountains, south to Persia and probably S. Afghanistan. Winters in eastern Africa from the Sudan south to Natal.

GENERAL HABITS. As in 670, q.v. In summer (on breeding ground) met with singly or in pairs; on autumn migration passage sometimes in loose parties or flocks of 6 to 20 (or more) roosting on stony scrubland in daytime, flying about erratically hawking winged insects at dusk, freely perching on telegraph posts and wires where available. On account of its swift and agile zigzag flight when chased, apparently is (or was, in the heyday of falconry?) much prized by the local sporting gentry in the Punjab as a quarry for trained hawks.

FOOD. Moths, crickets, grasshoppers, dung beetles (Copridae) and other insects.

VOICE AND CALLS. In summer described as a steady whirring note uttered both on the ground and from a bush or tree; call on the wing as very similar to that of Franklin's Nightjar (*C. a. monticola*), a sharp *choo-ee* or *sweesh*. A low chuckle when flushed during daytime (H. W. Waite).

NIGHTJARS

15

Female similar to male but with the spots on primaries smaller and fulvous-tinged; tail-spots fulvous, often somewhat vermiculated with brown.

STATUS, DISTRIBUTION AND HABITAT. Resident in W. Pakistan (Sind, Baluchistan [including coastal and central Makran], Afghan frontier districts); apparently only summer visitor (breeding) in some parts, e.g. Punjab Salt Range; in the plains and at moderate elevations up to c. 500 m in the arid hills. Breeds in Kutch; possibly also Saurashtra, Rajasthan and N. Gujarat. Widely but sparsely distributed in winter, straggling to W. Khandesh, Deccan (Ahmadnagar, Nasik), Konkan (Kalyan, Ratnagiri), south to N. Mysore (Belgaum). Recorded also from Simla and Delhi; not farther east than c. 77°E.¹ Affects environs of semi-desert cultivation, and stony wasteland cut up by dry torrent beds—sometimes sand dunes in pure desert dotted with sparse xerophytic bushes (*Caparris aphylla*, *Salvadora oleoides*, etc.). In winter frequently flushed in daytime from foot of grass tussocks on dried-up borders of jheels.

Extralimital. Afghanistan, SE. Iran.

GENERAL HABITS. As in 670 and other nightjars. 'More crepuscular than others of the genus; never sits on a tree' (T. R. Bell, c. 1905, Sind MS.). Sometimes found right out in rolling sandy desert, roosting in daytime in the shelter of a scraggy thorn bush topping a wind-rippled dune. In Sind has been observed coming out from the desert at dusk to hawk over a grassy swamp.

FOOD. Melolonthid beetles and other dusk-flying insects.

VOICE AND CALLS. 'Very like that of a frog, heard after sunset' (Nicol Cumming, Baluchistan). 'A long-continued purr like that of a Bustard-Quail (*Turnix taigour*)—*prrrrrrrrrrr*—but in a higher key, and softer. Always uttered when settled on ground' (T. R. Bell, Sind). A low, soft chuckle—*cluck cluck*—when flushed during daytime.

BREEDING. Season, overall February to August, mainly March to May. No nest. Eggs, 2, laid on bare stony ground in arid hummocky country or on salt-encrusted *pais* or *kallar* in semi-desert in the shelter of a *Caparris* or suchlike bush; also on tamarisk-covered sandy aits in the Indus (in Sind). Ground colour greyish white mottled all over with dark grey or brownish grey, and with secondary clouds of pale grey. Readily distinguished from other nightjars' eggs by general pattern of coloration—densely mottled grey rather than definitely marked or spotted. Average size of 36 eggs 28.8 × 20.9 mm (Baker). Incubation evidently by both sexes; period undetermined.

MUSEUM DIAGNOSIS. See Key to the Species. For details of plumage see Baker, loc. cit. 'In females the white spots on the three outer primaries are smaller and more suffused with buff than in males, especially on the third feather; the two outer tail-feathers entirely lack the white tips of the male, and have a buffish spot on the outer feather, or the two outer feathers, or no spot at all' (Tiechurst).

Chick (in down). 'General colour whitish isabelline and so rather paler than *univini* [673]; dark marks less pronounced than in *univini*, but in the same positions' (Tiechurst).

¹ A. E. Osmaston's specimen from Gorakhpur, U.P. c. 83°E. (JENHS 32: 541) is really a juvenile of *C. a. monticola* (vide Whistler, *ibid.* 38: 38), and Baker's record of a straggler in 'Punjab, W. Bengal' cannot be verified.

14

CAPRIMULGIFORMES

While a transient on passage, an occasional quick-repeated rather subdued *chuck-chuck-chuck-chuck* etc. of the quality and volume of a House Gecko's call (*Hemidactylus*), but faster (SA).

BREEDING. Season, May to July, principally June. No nest. Eggs, 2, laid on bare ground on the side of a stony hill or ravine, under shelter of a bush; somewhat variable, chiefly white or pinkish white, spotted with black all over the surface, with underlying secondary blotches, scrawls and smears of pale lavender-grey. Unconfusable with eggs of *C. a. monticola* or *C. maharattensis* often found in the same localities. Average size of 44 eggs 29.9 × 21.2 mm (Baker). Share of the sexes in the domestic chores, and incubation period, unrecorded.

MUSEUM DIAGNOSIS. See Key to the Species. Differs from the nominate race of Europe (for description of whose plumages etc. see Witherby, 1938, 2: 254-6) in being slightly paler and greyer. The white marks on the first three primaries of the male extend further, reaching the shaft of the feathers and often extending to the outer web. Female greyer and sandier than in *europaeus*.

1st and 2nd primaries of ♂, × c. 1
 (After Hartert)

Chick (in down). 'Almost completely clothed with down. General colour pale isabelline, paler than in *europaeus*; dark spots on head, wings and thighs black not brown as in *europaeus*' (Tiechurst).

MEASUREMENTS	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	172-192	c. 9-10	c. 16-17	(117) 125-144 mm (Baker, SA)

COLOURS OF BARE PARTS. Iris dark brown. Bill black. Legs and feet fleshy- or reddish brown.

673a. **Egyptian Nightjar.** *Caprimulgus aegyptius arenicolor* Severtzov
 (See Appendix, p. 258)

674. **Sykes's Nightjar.** *Caprimulgus maharattensis* Sykes

Caprimulgus Maharattensis Sykes, 1832, Proc. Zool. Soc. London: 83 (Maharattas [?])
 Baker, FBI No. 1628, Vol. 4: 369
 Plate 55, fig. 3

LOCAL NAMES. *Chhippāk*, *Chhāppa* (all nightjars—Hindi); *Shapter* (Baluchi).

SIZE. Myna ±; length c. 23 cm (9 in.).

FIELD CHARACTERS. As for the Genus, q.v. A small sandy grey semi-desert haunting nightjar, finely vermiculated above with wavy bars of light brown. See Key to the Species.

16

CAPRIMULGIFORMES

MEASUREMENTS	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	157-173	c. 18-20	c. 18-22	100-104 mm (Baker, SA)

Weight 1 ♂ 58, 1 ♀ 56 g (BNHS).

COLOURS OF BARE PARTS. Iris dark brown. Bill brown, pinkish at base, gape, and on commissure. Legs and feet pale fleshy brown; claws black.

 Baker, FBI Nos. 1623-4, Vol. 4: 364-5
 Plate 55, fig. 9

LOCAL NAMES. *Its kholi* (Assam); *Doo chuck* (Cachari); *Chupla* (all nightjars—Bihar).

SIZE. Pigeon ±; slenderer. Length c. 33 cm (13 in.).

FIELD CHARACTERS. As for the Genus, q.v. A medium-sized brownish buff forest nightjar of remarkably camouflaging plumage. See keys to Species and Subspecies, and Calls.

Female. Similar to male but with tips of outer tail-feathers pale yellowish buff instead of white as in the races *atripennis* and *arguabilis* (676, 677).

STATUS, DISTRIBUTION AND HABITAT. Resident and partially migratory. The Himalayan foothills up to c. 1800 m altitude (locally to c. 2200 m) in summer, and the submontane tract (terai, bhalar, dun, and duar) from Punjab through Himachal Pradesh, Garhwal, Kumaon, Nepal, Sikkim, Bhutan, and NEFA; Assam north and south of Brahmaputra river, and northern Nagaland. Distribution on western side south of sub-Himalayan Punjab (N. Maharashtra etc.) uncertain. Occurs in appropriate

NIGHTJARS, GOATSUCKERS

17

biotope in the Gangetic Plain east through Bihar to W. Bengal and E. Pakistan, Orissa and northern Andhra (in the E. Ghats) south to c. 18°N. lat. (Anantgiri), the population hereabouts being largely intermediate with the southern *atripennis* (676). Affects shady wooded nullahs in sal and moist-deciduous forest.

GENERAL HABITS. Crepuscular and nocturnal. Normally keeps singly or in pairs, squatting in daytime amongst dry leaves and debris in a shady nullah; astonishingly camouflaged in such surroundings. Occasionally a dozen or more birds may be flushed from a favourite spot, or be seen hawking in a rabble at dusk, like swallows, over a forest glade or clearing. Perches freely on trees, across a twig as well as lengthwise along a thicker bough, commonly calling from such positions or from the tip of a bare upright stem, silhouetted against the moonlit sky. Habitually squats in the middle of paths and forest roads, flying up and sailing around every now and again to hawk over the adjacent clearings in agile zigzag aerobatics, and sailing back to the same spot after each sortie. Sometimes even hovers in the air momentarily, and is capable of shuffling rapidly on the ground for a few paces when occasion demands. Rises abruptly from almost under an observer's foot, flying with silent wing flaps in front and squatting in his path again a short way ahead; will often do this repeatedly as the stroller advances. The eyes of the squatting bird gleam crimson-pink in the headlights of an oncoming car; it is expert at dodging clear in the nick of time by swift flop-flap turns and twists on the wing, but occasionally comes to grief.

FOOD. Moths, beetles, and other dusk- and night-flying insects. Among stomach contents the following specifically identified: *Catharsius sabatus*, *Oritis philemon*, *Orthopagus bonus*, *Apogonia carinata*, *Asyrus lateralis*, *Torymecus* sp., *Vespa orientalis*, *Opatrum* sp., coprid and carabid beetles, and hemipteran bugs (Mason & Lefroy, 1912).

VOICE AND CALLS. A distinctive, loud and resonant *chaunk*, *chaunk*, *chaunk*, *chaunk*, etc. reminiscent in the distance of heavy blows of a hammer or adze on a wooden plank; uttered from ground or tree. The calls are prefaced by hoarse croaks like a bullfrog's (*Rana tigrina*), the initial runs being of 2 to 4 quickly repeated *chaunks*, as if the bird was tuning up. The calling soon settles down to sustained runs of 50 *chaunks* or more each at the rate of about 5 *chaunks* in 4 seconds. With brief pauses, it is kept up almost incessantly from soon after dusk to dawn, the birds being particularly noisy during the breeding season.

BREEDING. Season, principally March to May. No nest built. Eggs, normally 2, laid in a scrubby nullah on the bare ground or a few dry leaves scraped together: pale creamy to deep rich salmon-buff, speckled and spotted with ashy grey and dull reddish brown. Average size c. 32 × 23 mm. Both sexes share in incubation; period undetermined.

MUSEUM DIAGNOSIS. See keys to the Species and Subspecies. In freshly killed birds three white or whitish bands on upperside of wing formed by the tips of greater, median, and longest lesser coverts conspicuous; in museum skins where wing cannot be pulled open, these less prominent.

Young (described from a juv. ♂, Nepal). Throat rufous; bars on abdomen and vent finer; tips of outer tail-feathers white on inner web and rufous on outer; spots on the primaries rufous (Binwas).

NIGHTJARS

19

YOUNG (immature) like female but with primaries much more barred with rufous, the notches and bars almost entirely disappearing in old birds.

MEASUREMENTS	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	168-189	20-24	16-19	121-133 mm (SA, HW, Koelz)

Weight 1 ♂ 74 g (SA).

COLOURS OF BARE PARTS. Iris brown; fine circumorbital ring yellow. Bill horny brown, yellowish on commissure and gape. Feet pinkish brown; claws pale horny brown.

Baker, FBI No. 1621 (part), Vol. 4: 363

LOCAL NAMES. None recorded.

SIZE. Pigeon ±; slenderer. Length c. 33 cm (13 in.).

FIELD CHARACTERS. As for the Genus and 675, q.v. See Keys and Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Southern Nagaland, Manipur, Mizo, and possibly the Chittagong Hill Tracts in E. Pakistan; from the foothills to c. 2400 m. Affects secondary scrub jungle, bamboo forest and open semi-cultivation.

18

CAPRIMULGIFORMES

MEASUREMENTS	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	207-228	20-24	19-21	146-179 mm (HW, SA, BB)

COLOURS OF BARE PARTS. Iris brown. Bill dark brown at tip, fleshy brown to reddish on base, commissure, and gape. Feet reddish to purplish brown; soles pinkish flesh.

676, 677. *Caprimulgus macrurus atripennis* Jerdon

Caprimulgus atripennis Jerdon, 1845, Ill. Ind. Orn., pl. 24

(Eastern Ghats to west of Nellore)

Caprimulgus macrurus aequabilis Ripley, 1915 Bull. Brit. Orn. Cl. 65: 40

(Trincomalee, NE. Ceylon)

Baker, FBI No. 1620, Vol. 4: 351

LOCAL NAMES. All nightjars: *Ashapprigadu* (Telugu); *Pādūkai kūrūci*, *Pādūngi* (Tamil); *Rā kili*, *Pā chawkan* (Malayalam).

SIZE. Pigeon —; slenderer. Length c. 28 cm (11 in.).

FIELD CHARACTERS. As for the Genus and 675, q.v. See Keys and Museum Diagnosis.

Female has tips of outer tail-feathers white as in male (contrast *albionotus*, q.v.).

STATUS, DISTRIBUTION AND HABITAT. Resident. Peninsular India (S. Maharashtra, Andhra, Mysore, Tamil Nadu, Kerala) roughly south of lat. 18°N., the northern and southern populations grading into one another. Affects evergreen and moist-deciduous biotope — partial to shady nullahs in mixed bamboo forest and secondary scrub jungle; chiefly foothills and up to c. 2000 m.

GENERAL HABITS AND FOOD. As in 675, q.v.

VOICE AND CALLS. A loud liquid chuckling *Avoo* or *Averoo* repeated every 2 seconds or so in runs of 15 minutes plus, throughout moonlit nights (SA). Rendered by Henry (in Sri Lanka) as 'a curious *grog*, *grogrog*' and the 'song' as 'a loud coughing bark *quaffrr* . . . *quaffrr* (!) repeated at intervals throughout the night, especially in moonlight'.

BREEDING. Season, overall March to July; mainly March and April. In Sri Lanka February to May, chiefly April, with a secondary season in August-September. Eggs, 2 typical of the nightjars' broad ellipse. Cream or pale salmon-coloured ('pale coffee' — Betts) boldly blotched and spotted with black. Laid on bare ground in a scrub-covered nullah. Size c. 30 × 22 mm (Baker). Both sexes incubate; period undetermined. Chick (clad in cinnamon down) capable of crawling away and hiding under leaves on alarm almost from the time of hatching.

MUSEUM DIAGNOSIS. See Keys; for details of plumage, Baker loc. cit.

20

CAPRIMULGIFORMES

Extralimital. Burma and southern Yunnan, south to Tenasserim, Thailand and the Indochinese countries.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 675 and other races, q.v. 'A chuckle resembling *Orch* . . . *orch*, *orch*, *orch* often precedes the usual *chaunking* call; another resembling *chock-a-chock* frequently uttered on the wing' (H. C. Smith, Burma).

BREEDING. Season, February to April, mainly March. Eggs, 2, normally pale yellowish creamy to warm pinkish buff, faintly blotched with lavender-grey or reddish grey. Average size of 60 eggs 31.3 × 22.6 mm (Baker).

MUSEUM DIAGNOSIS. See Key to the Subspecies. Size as in *albionotus* (675), but very dark in overall tone. Doubtfully distinct from *C. m. bimaculatus* of Malay Peninsula, Sumatra, etc.

MEASUREMENTS	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	195-223	c. 9-10	c. 19-20	168-181 mm (Baker)

COLOURS OF BARE PARTS. As in 675.

679. *Caprimulgus macrurus andamanicus* Hume

Caprimulgus andamanicus Anonymous = Hume, 1873, Stray Feathers 1: 470
(Jolly Boys Island, Andaman Islands)
Baker, FBI No. 1622, Vol. 4: 363

LOCAL NAMES. None recorded.

SIZE. Pigeon —; slenderer. Length c. 28 cm (11 in.).

FIELD CHARACTERS. As for the Genus and 675, q.v. See Keys and Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident; common in Middle and South Andaman Is. Apparently not yet recorded south of Macpherson Strait.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 675 and other races, q.v. Roosts during daytime among leaves on the forest floor, flitting out at dusk to hawk over mangrove swamps (Abdulali, 1964, JBNHS 61: 536).

BREEDING. Season, chiefly March-April. Eggs, 2, yellowish buff to deep salmon, blotched and spotted with blackish. Average size of 32 eggs 28.8 × 21.9 mm (Baker). Incubation by both sexes. 'Brooding bird when disturbed flew a few yards and kept moving about, raising wings and opening mouth' (Osmaston). If eggs removed, lays a second time within a yard or two of the same spot in 3 or 4 weeks, but not a third time (P. F. Wickham).

MUSEUM DIAGNOSIS. See Key to the Subspecies. Very similar to *peninsular atripennis* (676) but with the longitudinal black spots on crown more widely scattered and not confined to the centre. Pale markings on the wings usually more rufous.

MEASUREMENTS	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	172-186	c. 10-11	16-17	125-130 mm (Baker)

CAPRIMULGUS ASIATICUS Latham: INDIAN LITTLE NIGHTJAR

Key to the Subspecies

- Larger: wing c. 138 to 158 mm, tail c. 96 to 119 mm.....
C. a. asiaticus
 Smaller: wing c. 132 to 148 mm, tail c. 95 to 113 mm..C. a. eidos

680. *Caprimulgus asiaticus asiaticus* Latham

Caprimulgus asiaticus Latham, 1790, Index Orn. 2: 588 (India = Bombay)
Caprimulgus asiaticus gurgaoni Koelz, 1939, Proc. Biol. Soc. Washington 52: 80
 (Hattin, Gurgaon, Punjab [= Haryana])
 Baker, FBI No. 1630, Vol. 4: 372
 Plate 55, fig. 8

LOCAL NAMES. As for other nightjars generally, qq.v. *Chāpta* (Hindī); *Dāhi chāpta* (Gujarati).

SIZE. Myna ±; length c. 24 cm (9½ in.).

FIELD CHARACTERS. As for the Genus, q.v. A small-sized nightjar, narrowly but distinctly black-streaked above. Sexes alike. See Call; also Keys and Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. The most abundant and widely diffused nightjar of our area. West Pakistan (Sind, Punjab, Waziristan) and the entire Indian Union south of the Himalayan submontane belt (Nepal terai, Sikkim and Bhutan duars?) throughout the Peninsula south to Kanyakumari and Rameswaram I., east to Assam (N. Cachar) and East Pakistan (Comilla). A specimen collected at Mipi in the Dibang Valley (c. 1500 m alt.), SE. Tibet, on 13.v.1913 by F. M. Bailey (JBNS 24: 76). Mainly resident;

seasonal visitor to some parts. Local movements not yet worked out, the absence of calling during non-breeding season adding to the difficulties of investigation. Largely restricted to dry deciduous biotope; plains and hummocky foothills country; locally up to c. 1500 m in the outer Himalayas and peninsular hill ranges. Affects thin scrub jungle and fallow land with euphorbia hedges and thickets, and stony nullahs — usually in the neighbourhood of cultivation. Young forest plantations (teak etc.), and rambling jungly gardens in rural localities, are also favourite haunts.

Extralimital. Plains of Burma, southern Thailand, and southern Indo-chinese countries.

GENERAL HABITS. As of other nightjars, qq.v. Crepuscular and nocturnal; keeping in pairs or loose family parties, emerging from daytime retreat at

x c. 1

NIGHTJARS

23

681. *Caprimulgus asiaticus eidos* Peters

Caprimulgus asiaticus eidos Peters, 1940, Checklist of Birds of the World, 4: 211. New name for *Caprimulgus asiaticus minor* Parrot, 1907, Orn. Monatsb. 15: 170 (Vavuniya, Northern Ceylon). Nec *Caprimulgus minor* J. R. Forster Baker, FBI No. 1630 (part), Vol. 4: 372

LOCAL NAMES. All nightjars: *Bā bassā* (Sinhala); *Pādūkāi kūrci*, *Kuruttu pākshi* (Tamil).

SIZE. Myna ±; length c. 24 cm (9½ in.).

FIELD CHARACTERS. As for the Genus q.v., and 680. See Key to the Subspecies.

STATUS, DISTRIBUTION and HABITAT. Doubtfully distinct from South Indian birds of the nominate race. 'Resident. Common and widely distributed in suitable scrub country throughout the Dry zone, but not so plentiful in the Wet zone. Ascends the hills to about 3000 ft (c. 1000 m) in some districts' (Phillips).

GENERAL HABITS, FOOD, VOICE and CALLS. As in 680, q.v.

BREEDING. Season, January to October, but chiefly March to May, and again in September (Phillips). Eggs, 2, as in 680; size c. 27 × 20 mm.

MUSEUM DIAGNOSIS. Differs from south Indian birds only in smaller size; doubtfully also in tint of upperparts which seem somewhat darker and browner and colder in tone. But race perhaps redundant.

MEASUREMENTS			
	Wing	Bill (from skull)	Tarsus
♂ ♀	132-148	18-19	18-22
			95-113 mm (HW)

COLOURS OF BARE PARTS. As in 680.

682. Franklin's, or Allied, Nightjar. *Caprimulgus affinis monticola* Franklin

Caprimulgus monticolus Franklin, 1831, Proc. Zool. Soc. London: 116
 (Ganges between Calcutta and Benares)
Caprimulgus monticolus burmanicus Baker, 1931, Bull. Brit. Orn. Cl. 51: 102
 (Upper Chindwin, Burma)
 Baker, FBI No. 1629, Vol. 4: 370
 Plate 55, fig. 7

LOCAL NAMES. For all nightjars: *Chhippāh*, *Chhāpta*, *Dāchiri* (Hindī); *Torā* (Lepcha).

SIZE. Myna ±; length c. 25 cm (c. 10 in.).

FIELD CHARACTERS. As for the Genus, q.v. See Key to the Species and Museum Diagnosis. When squatted, a buff-coloured V extending roughly from shoulders to half-way down back is conspicuous.

Female has no white on tail-feathers which are all barred throughout; spots in the middle of first four primaries rufous-buff *centra* white in male.

STATUS, DISTRIBUTION and HABITAT. Common and widely diffused, but rather local. The submontane Himalayas (terai, bhabar, duns, and duars) from W. Pakistan and Punjab eastward to Assam (including Nepal, Sikkim, and Bhutan), normally up to c. 1200 m alt. (Garhwal etc.), exceptionally

22

CAPRIMULGIFORMES

dusk, squatting in the middle of dusty cross-country roads or on milestones, fence posts and the like, and calling. Habitually squats in the middle of cart tracks and kutcha motor roads for dusting or as hunting bases.

FOOD. Moths (Heterocera), beetles (Coleoptera), bugs (Hemiptera) and other dusk-flying insects. Specifically recorded among stomach contents are dung beetles (*Onthophagus* spp.), water beetles (Dysticidae), and crickets (*Gryllus* spp.).

VOICE and CALLS. A familiar, rather ventriloquistic *chuck-chuck-chuck-r-r-r* usually uttered from some elevated perch such as a stake or stone. To those acquainted with icy conditions, call aptly reminiscent of a stone skipping along a frozen pond as in the game known as 'ducks and drakes'. Repeated monotonously with short breaks for hours on end, most vigorously after dusk and at early dawn, especially during the breeding season when two birds or more in the distance will frequently answer one another. Also particularly vocal during moonlight nights. While calling the whole bird 'vibrates' from head to tail. A low chuckle — *chūk-chūk* — during the silent (non-breeding) period, chiefly on the wing.

BREEDING. Season not well defined; chiefly between February and September, the peak periods variable locally. No nest built. Eggs, 2, laid on the bare ground in thin bamboo jungle or open scrub country — even in jungly compounds in mofussil towns; long cylindrical ovals, normally cream coloured or pale pink to salmon, spotted and blotched with reddish brown and inky purple. Average size of 100 eggs 26.5 × 19.9 mm (Baker). Evidently both sexes share incubation; period undetermined.

MUSEUM DIAGNOSIS. See Keys; for details of plumage Baker, loc. cit.

As noted by Whistler (JBNS 38: 38) there are at least three distinct colour phases — pale sandy, brown, and grey — apparently adapted ecologically, the pale sandy birds coming mostly from the north-west, the grey birds mostly from the Deccan, and the brown birds from other localities. The phases grade into each other, and there are so many exceptions besides that attributing subspecific significance to them is dubious. (Cf. Koelz's *C. a. gurgaoni* from the Punjab described by its author as 'very much paler throughout' than S. Indian birds.)

MEASUREMENTS			
	Wing	Bill (from skull)	Tarsus
♂ ♀	138-158	17-19	c. 20-22
			96-119 mm (Baker, HW, SA)

Weight 1 ♂ 46, 1 ♀ 42 g (SA).

COLOURS OF BARE PARTS. Iris brown; fine circumorbital ring yellow. Bill horny brown, yellowish on commissure and gape. Legs and feet pinkish brown; claws pale horny brown.

Left foot, x c. 1

24

CAPRIMULGIFORMES

c. 1800 to 2400 (Simla hills — Jones, JBNS 29: 286); also Assam south of Brahmaputra river, Nagaland, Manipur, Mizo and E. Pakistan. South through Rajasthan, Kutch, Saurashtra and Gujarat, eastward and southward throughout the peninsula to Bengal and Kerala. Mainly resident; described in many parts as summer visitor (April to July) or passage migrant (sometimes loose flocks of 7 or 8); thus in Rajasthan (Mt Abu), Punjab (Salt Range and Ambala dist.), Delhi State, Madhya Pradesh (Mhow neighbourhood), U.P. (Ghazipur dist.) and other localities. But local movements unclear, the absence of ringing data and of the bird's diagnostic calls during non-breeding season adding to the uncertainties. Affects bare, sparsely scrubbed hillsides cut up by nullahs with thorn scrub and stunted trees, and dry stony stream-beds interspersed with outcoursed aits covered with pampas grass and thorny bushes. Also light deciduous forest and grassland with outcrops of sheet rock here and there, and thin jungle in the neighbourhood of cultivation.

Extralimital. Burma, Thailand.

GENERAL HABITS and FOOD. Not significantly different from 670, 675, and other nightjars, qq.v. Crepuscular and nocturnal. Drinks regularly at forest pools on emergence from daytime retreat at sundown, flying over the water and dipping down to it like a swallow. Possibly water also conveyed to downy young by wetting underplumage in this way. Appears at dusk and flies high, sailing up and down over forest, cultivation, and dry water-courses, occasionally alighting on a tree-top or squatting on the ground.

VOICE and CALLS. Distinctive and diagnostic: a loud, sharp and penetrating single note *sceesh* (rendered also as *choo-ee* or *chees*) reminiscent of the sound of a whiplash cutting the air. Uttered at intervals of 4 or 5 seconds off and on all through the night from a perch as well as on the wing. The calls commence even before dark and often continue till after dawn in the breeding season; the birds particularly vocal on moonlight nights. A low chuckle when flushed during daytime. Another call, not heard by us or recorded by other observers, has been described by a reliable Madhya Pradesh ornithologist (E. A. D'Abreu, JBNS 28: 806) as *wakh*, *wakh*, *wakh wakh*, apparently uttered in the breeding season. This call needs verification.

BREEDING. Season, overall March to August, chiefly March, April and May but the peak periods vary with locality. No nest built. Eggs, 2, laid on the bare ground in the shelter of a grass tuft in dry watercourses or scanty deciduous forest, and in similar locations: pale salmon pink to rich deep salmon, spotted and blotched with deep red and red-brown, with underlying marks of lavender-pink. Average size of 40 eggs 30.2 × 22.1 mm (Baker). Both sexes share incubation; period undetermined.

MUSEUM DIAGNOSIS. See Key; for details of plumage Baker, loc. cit.

Chick (in down). Pinkish brown (H. W. Waite).

Genus COLLOCALIA G. R. Gray

Collocalia G. R. Gray, 1840, List Gen. Bds.: 8. Type, by original designation, *Hirundo esculenta* Linnaeus

For characters see Key (above). The genus contains the so-called 'Edible-nest Swiftlets' which build nests of inspissated saliva from the sublingual salivary glands which undergo a remarkable development during the nest-building season. The 'white' nests of certain species, which look like isinglass, are highly relished by the Chinese as an epicurean delicacy. As an article of commerce the best-quality ones fetch several times their weight in silver in eastern markets.

Many of the species and subspecies are very similar superficially and difficult to identify from museum skins alone. The group has been subjected to a succession of controversial taxonomical revisions and reshuffling adding in no small measure to the confusion and uncertainty in the prevailing and old published records. However, each species is believed to build a characteristic nest, and where more than one species inhabit the same cave it is claimed to be possible to differentiate them satisfactorily by the nests. See 'The Identification of Malaysian spp. of Swiftlets, *Collocalia*' by R. W. Sims (1961, *Ibis* 103a: 205-10) and 'The Identity of *Collocalia fusciphaea* (Thunberg)' by Lord Medway (1961, *ibid.*: 625-6); also 'Field characters

SWIFTS

27

insects high up over river valleys, defiles, etc. often in company with House Martins and other swifts. As characteristic of this genus the flight, which is rather slow for a swift, is punctuated from time to time by interludes of a pipistrelle-like fluttering. Roosts in enormous 'clusters', clinging like pipistrelles to the rough rock face inside caves and grottoes, or to old nests or their stubs, in a vertical position, head upwards. Din made by roosting birds also very reminiscent of the soft screeching of a colony of these small bats. The birds leave the roost well before dawn, often wandering considerable distances in the course of the day's foraging and making erratic appearances in far-flung areas. They do not return to the cave till well after dusk, except during the breeding season when rabbits constantly fly in and out all day long. The ease and suddenness with which the birds are evidently able to adapt their vision to the pitch-dark interior of a cave as they drop vertically from aloft and shoot in through a narrow fissure from the brilliant sunshine outside and find their way through dark caverns to their own nest among the hundreds of others, cheek by jowl, is quite astonishing, but this is no doubt largely effected by echo-location.

FOOD. Mainly dipterous and hymenopterous insects captured in the air. Drinks from surface of a pool by flying down to it at a tangent.

VOICE AND CALLS. Apart from the conversational twittering *chit-chit* uttered at roost, has a low rattle-like call as of a knitting needle drawn across a few teeth of a wooden comb. It is this rattle-like call that serves in echo-location in dark caves (Medway).

BREEDING. Season, April to June. *Nest*, a tiny, unlined cup of agglutinated moss with the rim slightly sloping down from the vertical rock-wall to which it is attached like a bracket with the bird's inspissated saliva. Built in colonies close to and often touching one another, haphazard and in rows in angle of ceiling, not clustered together in 'villages' (cf. House Swift), the nests pock-marking large areas of the rock face or ceiling within dark grottoes. Diameter of cup c. 6 cm, depth inside c. 2 cm, with a slightly tapering pedestal below, c. 5 cm thick. The side of the nest adhering to the wall projects upwards giving increased purchase. (For a very good account of a nesting cave in Chakrata dist., U.P. see E. A. Glennie, 1944, JBNHS 44: 593-7.) *Eggs*, 2, white, ellipsoid, narrowing slightly at one end. Average size of 8 eggs 21.8 × 14.6 mm (Baker). Share of the sexes in incubation, and period, undetermined.

Copulation, as in some other swifts (cf. Alpine Swift), has been observed in the air, as well as at nest.

MUSEUM DIAGNOSIS. See Key to the Species. Differs from S. Indian *C. unicolor* in being somewhat larger, darker and glossier on upperparts, and with paler rump.

MEASUREMENTS	Bill	Tarsus	Tail
Wing	(from skull)		central outer
♂ ♀ 120-133 ¹	8-9	[c. 8]	45-48 54-59 mm. (HW)

b Wing mostly under 123 mm; tarsus bare; tips of downy bases of mantle and rump feathers white		
3 Rump concolorous with back; wing mostly under 115 mm.....	<i>C. unicolor</i>	29
4 Rump paler than back; wing mostly over 115 mm..	<i>C. fusciphaea</i>	31

COLLOCALIA BREVIROSTRIS (Horsfield): HIMALAYAN SWIFTLET

Key to the Subspecies

Smaller; wing c. 120-133 mm, mostly over 125 mm	<i>C. b. brevirostris</i>
Larger; wing c. 132-141 mm.....	<i>C. b. innominata</i>

683. *Collocalia brevirostris brevirostris* (Horsfield)

Hirundo brevirostris Horsfield, 1840, *Proc. Zool. Soc. London*: 155 (Assam) Baker, FBI No. 1609, Vol. 4: 348

Plate 56, fig. 2

LOCAL NAMES. None recorded.

SIZE. Sparrow —; length c. 14 cm (5½ in.).

FIELD CHARACTERS. A small, slender, slightly fork-tailed brown swift with narrow but rather swallow-like wings. *Above*, dark brown with a noticeably paler rump; *below*, uniformly greyish brown. Sexes alike. Usually distinguishable in the air from other swifts as a *Collocalia* by the occasional interludes of a seemingly laboured pipistrelle-like fluttering while in normal hawking flight.

STATUS, DISTRIBUTION AND HABITAT. Resident. The Himalayas from about 76°E. long. in Himachal Pradesh (Kangra, Dalhousie) eastward through Nepal, Sikkim and Bhutan to NEFA; also Assam hills north and south of Brahmaputra river, Nagaland, Manipur, Mizo, and E. Pakistan hills (?). From the foothills to c. 3600 m altitude.

Extralimital. Burma, Thailand.

GENERAL HABITS. Gregarious; living in large colonies in dark underground limestone caves, spending most of the day on the wing hawking

28

APODIFORMES

684. *Collocalia brevirostris innominata* Hume

Collocalia innominata Hume, 1873, *Stray Feathers* 1: 294 (Andaman Islands; type from Port Mout, S. Andaman I.)

Collocalia inopina Thayer & Bangs, 1909, *Bull. Mus. Comp. Zool.* 52: 139 (Maifuling, 5000 ft, Hupeh, China)

Collocalia fusciphaea [sic] *capitis* Thayer & Bangs, 1909, *Bull. Mus. Comp. Zool.* 52: 139 (Hupeh Prov., China) Baker, FBI No. 1610, Vol. 4: 349

LOCAL NAMES. None recorded.

SIZE. Sparrow —; length c. 13 cm (5¼ in.).

FIELD CHARACTERS. As for 683, q.v. Not distinguishable from it in the field, and only with difficulty in the hand. See Museum Diagnosis. Could be confused with Palm Swift (708) but is slightly larger and with a noticeable grey band across rump.

STATUS, DISTRIBUTION AND HABITAT. Probably a winter straggler to the Andaman Is., the type, collected at Port Mout in S. Andaman, being the only definite record. Observed on Narcondam (lat. 13°26'N.) and 'they probably breed in the caves along the south coast of the island' (Osmaston, 1905, JBNHS 16: 621).

Extralimital. Central China (Hupeh Prov.), SW. Thailand, Malay Peninsula, Sumatra, but subspecies equivocal (see Medway, 1966: 163).

GENERAL HABITS, FOOD. Presumably as in 683.

VOICE AND CALLS. Unrecorded.

BREEDING. *Extralimital.* Nests 'black', of agglutinated moss etc. as in 683 and likewise inedible.

MUSEUM DIAGNOSIS. *Above* blackish brown, the crown and nape still darker, sometimes forming a distinct cap; rump usually paler and more grey with dark shaft-stripes. *Below*, greyish brown, the feathers with darker shaft-stripes.

MEASUREMENTS	Wing	Bill	Tarsus	Tail
		(from feathers)		
♂ ♀ 125-132		c. 4	c. 8	52-55 mm (Baker)
Tail fork slight, 3-7 mm				
Wing 132-141; depth of tail fork 8-10 mm — Sims!				

COLOURS OF BARE PARTS. Iris dark brown. Bill black. Legs and feet brownish black.

684a. *Indomalayan* or 'Black-nest' Swiftlet. *Collocalia maxima maxima*¹ Hume

Collocalia maxima Hume, 1878, *Stray Feathers* 6: 49 (Tenasserim) Baker, FBI No. 1609, Vol. 4: 348 (*C. b. brevirostris*)

LOCAL NAMES. None recorded.

SIZE. Sparrow —; length c. 14 cm (5½ in.).

FIELD CHARACTERS. As for *brevirostris* (683), q.v. Practically indistinguishable from it in the field, but slightly heavier build, proportionately broader wings and less forked tail suggestive. See Museum Diagnosis.

¹ Formerly *Collocalia leucorhynchos* Stresemann.

SWIFTS

29

STATUS, DISTRIBUTION and HABITAT. Eastern Bhutan and NEFA (?). Specimens (in British Museum) collected by F. Ludlow between c. 2100 and 3900 m alt.

Extralimital. East to Thailand, Vietnam, Malaya, Sumatra, Java, and Borneo.

GENERAL HABITS, FOOD, VOICE and CALLS. Not specifically recorded. Doubtless as in 683, by and large. Utters the rattle call for echo-location (Medway).

BREEDING. Data for our area lacking, but in Malaysia known to build 'black' nests, i.e. with an admixture of feathers in the cup of hardened white saliva, fixed to a cave wall.

MUSEUM DIAGNOSIS. Distinguishable from *C. b. brevirostris* (683) by proportionately broader wing, less deeply forked tail, and a thickly, *contra* sparingly, feathered tarsus.

MEASUREMENTS

	Wing	Tail
7 ♂♀	128-135	50-58 mm; furcation 11-15 per cent against 15-20 per cent in <i>brevirostris</i> (Medway, 1961, JBNHS 59: 149)

COLOURS OF BARE PARTS. As in 683.

685. Indian Edible-nest Swiftlet. *Collocalia unicolor* (Jerdon)

Hirundo unicolor Jerdon, 1840, Madras Jour. Lit. Sci. 11: 238 (Coonoor Pass)
Baker, FBI No. 1608, Vol. 4: 346

Plate 56, fig. 8

LOCAL NAMES. *Wihhi lhinija* (Sinhala); *Kudukarya* (Veddah); *Sārāpākshi* (Malayalam).

SIZE. Sparrow—; length c. 12 cm (4½ in.).

FIELD CHARACTERS. A tiny slender blackish brown swift with a slightly forked tail and the same peculiar rapidly-flapping pipistrelle-like flight as 683, q.v. Sexes alike. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident. The coastal and Western Ghats strip from about Ratnagiri (c. 16°N. lat.) in S. Konkan (Maharashtra) southward through Goa, W. Mysore, W. Tamil Nadu, and Kerala, including the Nilgiri, Palni, Brahmagiri and associated hill ranges, and rocky offshore islets with natural caves and grottoes; from sea level to c. 2200 m altitude. Abundant also throughout Ceylon. Wandering over a considerable radius from its roosting and nesting caves during the day's foraging, making erratic appearances in distant localities.

GENERAL HABITS. As of 683, q.v. Huge colonies inhabit natural caves and grottoes in the cliffs of hills of the Western Ghats complex, and rocky islets on the Malabar coast. Swarms of the birds arrive in the gathering dusk, dropping from the sky like flurries of falling leaves and shooting in through the narrow fissures and 'skylights' leading into the underground caverns, with remarkable adroitness. They leave again in the darkness of early dawn announced only by the rush of wings, like waves on a sandy beach, as if to make way for the daytime occupants of the caves, the bats, just then returning from their nocturnal foraging.

SWIFTS

31

MISCELLANEOUS. Till about the turn of the century the right to collect the nests of this swiftlet for export to China was auctioned by the Government of Bombay, but the business was never considerable. From about Rs 200 to 250 per year around 1865, the realized fee dwindled to only Rs 41 in 1895. Thereafter the business appears to have faded out largely owing to decreasing returns, perhaps as a result of over-exploitation of the colonies, and the disproportionate risks and organization involved in collecting the nests. The main localities which supplied the nests were Vengurla Rocks (or Burnt Islands) off the Malvan coast (Maharashtra), and Pigeon Island (also known as Netrani or Nitrān) off the coast of North Kanara (now in Mysore).

686. Andaman Grey-rumped or 'White-nest' Swiftlet. *Collocalia fuciphaga inexpectata* Hume

Collocalia inexpectata Hume, 1873, Stray Feathers 1: 296, in text (Andaman Islands)
Baker, FBI No. 1612, Vol. 4: 350

LOCAL NAMES. None recorded.

SIZE. Sparrow—; length c. 12 cm (4½ in.).

FIELD CHARACTERS. As of 685, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident and common in the Andaman Islands; evidently less so in the Nicobars. Colonies nesting in rock-caves by the shore on South Buton, Neill, Chiriyā Tapu, S. Cinque and other islands. Also observed on Car Nicobar.

GENERAL HABITS. As in 683 and other swiftlets. Hawks all day over mangroves, rubber plantations, forest, and cultivation.

FOOD, VOICE and CALLS. Not specifically recorded.

BREEDING. *Season*, chiefly March and April. *Nest*, white, opaque and translucent, of clear inspissated saliva with little or no admixture of extraneous matter; thus of the best edible and commercial quality. More or less half-cup shaped, c. 6 cm across × 1.5 cm deep; attached bracketwise or close to one another to the rock wall in sea caves, in small colonies of a few nests to large ones of several hundred. Weight of each nest c. 14 g. Eggs, 2, white, long ovals with little or no gloss (Osmaston, 1906, JBNHS 17: 486). Average size of 48 eggs 20.2 × 13.6 mm (Baker). Incubation period and other details of breeding biology unrecorded.

MUSEUM DIAGNOSIS. *Above*, blackish brown, darkest on crown, wings, and tail. A paler but ill-defined (sometimes obsolete) rump-band. *Below*, pale greyish brown, the feathers often dark-shafted.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂♀	113-121	c. 4-5	c. 9	49-53 mm (Baker, HA)

Depth of tail fork 6-8 mm (Sims).

COLOURS OF BARE PARTS. Iris dark brown. Bill black. Legs and feet dark brown.

MISCELLANEOUS. High medicinal, dietetic and tonic (also aphrodisiac) properties are ascribed to the nests by the Chinese. Analysis by C. J. House showed the clear saliva nests ('white' nests) to be highly nitrogenous

30

APODIFORMES

FOOD. Chiefly dipterous, hemipterous and hymenopterous insects. About 80 per cent of the stomach contents of four examples taken in the roosting cave on Vengurla Rocks in February comprised two species of the harmful jassid 'mango-hopper' (*Idiocerus nicosparus* and *I. atkinsoni*) obviously captured over the renowned mango orchards of Ratnagiri dist. on the opposite mainland. The rest of the food items included representatives of Hemiptera, Coleoptera, Odonata, Hymenoptera, Diptera and Trichoptera. (For a fuller list see Abdulali, 1942, JBNHS 43: 450.) In Ceylon, observed hawking insects at lights (over club house) and feeding its nestlings far into the night (E. Kershaw, June 1967, Ceylon Bird Club Newsletter).

VOICE and CALLS. As in 683, q.v. All through the night the roosting birds keep up a feeble but shrill clicking or twittering *chit-chit*, with distinct livelier choruses intermittently. 'Very harsh call-note, reminiscent of the Whiskered Tern' (R. S. P. Bates, MS.).

BREEDING. *Season*, chiefly March to June in South India; March to September in Ceylon. *Nest*, as in 683 but whitish and less mixed with extraneous matter such as grass, moss, and feathers, the attachment practically of pure coagulated saliva; thus of some gastronomic and commercial value. Often hundreds of nests clustered densely, 5 to 10 cm from one another in patches on the rock-wall or ceiling of dark grottoes. 'They look at a distance exactly like deep oyster shells with one side flattened, the saliva where it is smoothed down having a pearly appearance' (Vidal, 1881, SF 9: 44-8, q.v. for other details). The nests usually swarm with bugs, identified from the Vengurla colony as the Bed Bug, *Cimex rotundatus*. Eggs, 2, white, long blunt ovals. Average size of 80 eggs 20.9 × 13.5 mm (Baker).

MUSEUM DIAGNOSIS. Almost identical in coloration with Himalayan *C. b. brevirostris*, only a shade paler and less glossy on the upperparts and with rump colorous with back (not paler). Smaller in size.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail central outer
♂♀	113-117	c. 8-9	—	41-45 48-55 mm (HW, SA)

(*vide* Baker, Wing 105-115; tarsus c. 8.9 mm)

Weight 2 ♂♂ 11, 11g (SDR).

COLOURS OF BARE PARTS. Iris dark brown. Bill black. Legs and feet purplish black.

* The group of so-called 'cave swiftlets' is distinguished by echo-location, evidently being the only birds which build their nests in the dark, with no light orientation. (Baker, 1917: 497-503.)

* The sublingual salivary glands enlarge at nest-building time to provide the necessary cement and gradually regress to normal thereafter. It was believed, and still widely is, that the first built nest is comparatively free from admixture of grass, moss and feathers. The second, built after this one has been removed by the nest-gatherer, contains a greater quantity of extraneous matter and is less valuable, whereas the third (and sometimes fourth) is almost entirely of pure saliva. These facts, however, suggest however that actually the first or second or third.

32

APODIFORMES

material, containing nearly 50 per cent protein and 7½ per cent of mineral matter, mostly lime. [See article 'A description of the swifts (*Collocalia francica* [= *fuciphaga*] and *C. innominata*), the birds which build edible nests' by F. H. Giles, 1936, Jour. Siam nat. Hist. Soc. 10 (2), Supplement (November).]

687. Beavan's or Whitebellied Swiftlet. *Collocalia esculenta affinis* Beavan

Collocalia affinis 'Tytler' = Beavan, 1867, Ibis: 318
(Port Blair, South Andaman Island)
Baker, FBI No. 1614, Vol. 4: 352
Plate 56, fig. 3

LOCAL NAMES. None recorded.

SIZE. The smallest of our swiftlets. Length c. 10 cm (4 in.).

FIELD CHARACTERS. As of 683 and 685, qq.v., but distinguishable by smaller size, glossy blue-black upperparts and white belly. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Resident and common in the Andaman and Nicobar Islands.

GENERAL HABITS. Gregarious, abundant, and tame. Flies freely in and out of residential bungalows and office buildings in the settlements while hawking, unmindful of the human inmates. Roosts and nests in small numbers or vast colonies in factory sheds, tool houses and the like. The congregation keeps up a continual sharp bat-like clicking and twittering, often quite deafening at confined close quarters. The birds cling in clusters to old nests as well as those in occupation, and to roughnesses on walls and ceiling boards—upside down (back horizontal with the ground)—sometimes two or three individuals on the same foothold. Their bodies heave up and down as if panting heavily, but the birds are evidently quite comfortable in this position, at times even preening themselves. Others fluttering around in search of a foothold will hang on to the legs or wing-tips of those already settled, and thus may soon form a cluster of half a dozen or more. Nest material (moss, lichens, etc.) is plucked from the boughs of lofty trees, while the bird hovers momentarily in its flight through the mossy branches.

FOOD, VOICE and CALLS. Not specifically recorded as different from other swiftlets. Has no echo-locating calls.

BREEDING. *Season*, December to April, principally February and March. *Nest*, 'black', inedible, and of no commercial value; made entirely of vegetable matter, e.g. moss, lichens, casuarina needles, coconut fibre, agglutinated with the birds' saliva. Shallow, flat-bottomed half-cups (c. 7 × 5 cm in outside diameter and c. 2 cm deep) attached like brackets to the substrate with brownish saliva; usually vast colonies in sawmill sheds, etc. clustered densely along wall near angle with ceiling, the nests often touching and built partly upon one another in a disorderly jumble. Eggs, 2, white, long, elliptical. Average size of 100 eggs 17.5 × 11.2 mm (Baker). Both sexes incubate; period undetermined. The birds relieve each other at the nest by seemingly violent supplanting, the relief clinging to the nest, nudging, pushing, and blowing out the sitter and literally usurping its place. But the proceedings equivocal since sometimes two, and even three, birds will try to supplant a sitting bird in this way; then again, the relief

SWIFTS

33

on being repulsed from one nest will successfully dislodge a brooding bird on another nest nearby and usurp its place on the eggs!

MUSEUM DIAGNOSIS. Tarsus naked; tail unforked. For details of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	91-100	c. 3-4	8-9	36-39 mm (Baker)

COLOURS OF BARE PARTS. Iris deep brown; bill, legs and feet black.

Genus CHAETURA Stephens

Chaetura Stephens, 1826, in Shaw's Gen. Zool. 13 (2): 76. Type, by subsequent designation, *Chaetura pelagica* Stevens (sic) = *Hirundo pelagica* Linnaeus

Rhaphidura Oates, 1883, Bds. Burma 2: 6. Type, by monotypy, *Acanthylis leucopygialis* Blyth

Indiepus Mathews, 1918, Bds. Austr. 7: 265. Type, by original designation and monotypy, *Acanthylis sylvatica* Tickell

Hirundo-opus Hodgson, 1837 (1836), Jour. Asiat. Soc. Bengal 5: 780. Type, by original designation and monotypy, *Cypselus* (*Chaetura*) *nudipes* Hodgson Cf. Lack, D.: 1956, Auk 73: 9-12, 26.

Characterized by the tail-feathers having rigid shafts the ends of which project as spines or needles for some distance beyond the web. Tarsi naked; all four toes forwardly directed as in *Apus*; claws strong and much curved. Wings very long and pointed: first primary (as.) longest.

Genus represented in the Ethiopian, Oriental, Australian and Holarctic regions. Three species within Indian limits.

Key to the Species

	Page
1 Larger. Wing over 180 mm; colour of back paler than surrounding parts

Chaetura cochinchinensis rupchandi Biswas, 1951, Ardea 39: 320

(Hitaura, central upper Nepal Terai)

Baker, FBI No. 1603 (part), Vol. 4: 340

LOCAL NAMES. None recorded.

SIZE. Bulbul ±; stouter. Length c. 20 cm (8 in.).

FIELD CHARACTERS. As of 688, q.v. See Key to the Subspecies.

STATUS, DISTRIBUTION AND HABITAT. Range not known. Collected in central Nepal terai, c. 600 m. Apparently a lower-elevation form than 688.

GENERAL HABITS, FOOD, VOICE AND CALLS. Presumably as in 688. Nothing specifically recorded beyond that 'it was observed from time to time in small flocks of about a dozen birds around Hitaura in the central dun [Nepal] during June-July; sometimes flying fairly low; within a few feet of the ground and parallel to it' (Biswas).

BREEDING. Unknown.

MUSEUM DIAGNOSIS. See Key.

MEASUREMENTS

Plate 56, fig. 11

LOCAL NAME. *Dao hadi gadeba* (Cachari).

SIZE. Bulbul ±; stouter. Length c. 20 cm (8 in.).

FIELD CHARACTERS. As of 688, q.v. See Key to the Subspecies and

Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Apparently common in Assam hills south of Brahmaputra river, Nagaland, Manipur, Mizo; probably also E. Pakistan hill tracts.

Extralimital. Burma, Malaysia, Indochinese countries.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 688.

34

APODIFORMES

SIZE. Bulbul ±; stouter. Length c. 20 cm (8 in.).

FIELD CHARACTERS. A large blackish brown swift with long narrow pointed bow-shaped wings and short tail. Underwing uniform blackish.

Adult. Above, glossy black except for back which is pale brown, whitish in the centre. Below, chin, throat, and under tail-coverts white. Rest of underparts dark brown with a whitish patch on each flank. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. The entire Himalayas from Hazara dist. in W. Pakistan eastward through Nepal, Sikkim and Bhutan to NEFA, normally between c. 1250 and 4000 metres elevation. Rather uncommon everywhere; local and patchy. Affects the neighbourhood of crags and rock scarps.

Extralimital. SE. Tibet eastward to W. Yunnan and W. Szechuan.

GENERAL HABITS. Justly reputed to be one of the fastest fliers among birds. Keeps in small loose parties and flocks hawking insects individually high over river valleys and upland pastures ranging over enormous distances in the day's foraging. The birds dash about with seemingly unhurried and effortless strokes of the long narrow wings, and glide and swish round crags and contours at phenomenal speed. The wings produce a peculiar musical swishing sound as they hurtle through space, high overhead at one moment vanishing in the distance the next, like a jet fighter plane. They descend to hawk lower in cloudy weather, especially after a thunderstorm, and drink by stooping down to water at a tangent and scooping sips as they momentarily skim along above the surface on quivering wings. Roosts at night (presumably also nests) in colonies, clinging to rough rock walls within clefts and fissures — possibly also in hollow boles of trees.

FOOD. Flying insects, chiefly Coleoptera, Hemiptera and Hymenoptera.

VOICE AND CALLS. Loud, shrill and lively 'screams' uttered in flight, particularly at dusk, while a rabble is disporting itself in the air round the roosting cliff prior to retiring. 'When wounded they utter a screeching sound like churr-r churr-r churr-r' (Tytler, 1868, *Ibis*: 196).

BREEDING. Presumably more or less as in 691, q.v., in clefts of rock up in the mountains; possibly also within hollow tree-trunks. Nothing definitely known beyond that an oviduct egg (white, 31.2 × 22.4 mm) was obtained by Baker from a female he shot in N. Cachar on 14 April (1899).

× c. 1 (After Hartert)

MUSEUM DIAGNOSIS. See Key; for details of plumage Baker, loc. cit.

Differs from the palaearctic nominate race in being more glossy on crown and nape and lacking white on forehead. For description of plumages and structure (also bionomics) of the nominate race see Witherby, 1938, 2: 249-51.

36

APODIFORMES

BREEDING. Practically unknown. Baker took an oviduct egg from a female shot on 26 May. It was white and measured 28.1 × 21.0 mm.

MUSEUM DIAGNOSIS. Differs from *C. c. nudipes* in being darker both above and below, with the chin and throat grey instead of white.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	183-184	c. 8	c. 16	48-49 mm (Baker)

COLOURS OF BARE PARTS. As in 688.

691. Large Brownthroated Spinetail Swift. *Chaetura gigantea indica* Hume

Chaetura indica Anonymous = Hume, 1873, Stray Feathers 1: 471

(Andaman Islands and southern India)

Baker, FBI No. 1605, Vol. 4: 343

Plate 56, fig. 10

LOCAL NAMES. *Dao hadi gadeba* (Cachari); *Sārāpākāhi* (Malayalam); *Wāhi lūhīnī* (Sinhala).

SIZE. Myna ±; length c. 23 cm (9 in.).

FIELD CHARACTERS. A large blackish brown swift with long, narrow, pointed bow-shaped wings and short squarish tail with needles projecting from the feathers — noticeable in flight under favourable conditions. The white under tail-coverts contrasting with the very black-looking underparts, and high speed, are further suggestive clues.

Adult. Above, glossy metallic black except for centre of back which is pale brown. A black spot in front of each eye, and a white spot on either side of forehead. Below, chin and throat pale brown, under tail-coverts white. Rest of underparts dark brown with a white patch on the flanks above the thighs. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Resident; described also as local migrant in some parts, but movements as yet not understood. Assam, Nagaland, Manipur and Mizo; E. Pakistan hill tracts; the Western Ghats strip from Goa and N. Kanara (c. 15°N. lat.) southward through W. Mysore, W. Tamil Nadu (including Nilgiri, Palni and associated hills) and Kerala; Ceylon; Andaman Islands, (Nicobars ?); from the seacoast to the mountain tops. Affects evergreen and moist-deciduous biotope.

Extralimital. Burma, Thailand, Indochinese countries.

GENERAL HABITS. Keeps in small parties of 4 or 5 birds or larger flocks ('rabblies') of up to 50 or more, sweeping the daylight hours on the wing, hawking in long back-and-forth sweeps high over forested valleys and grassy hilltops, flying at astonishing speed — here one moment, gone the next. Along with the Whitethroated Spinetail and Alpine Swift, reputed to be one of the fastest fliers among birds, estimates of 250-300 km per hour being mentioned. The wings produce a loud twanging sound ('as of a harp string') as the birds hurtle past overhead. The spines projecting from the tail-feathers, in addition to providing support when the bird is clinging to a vertical surface with both feet, possibly conduce to streamlining for

SWIFTS

37

speed. In normal cruising flight, the tail is fairly spread out; when the bird is shot at with a gun and thoroughly scared, the tail is narrowed down to a point and the bird then streaks through space at a velocity that is truly spectacular. Usually descends to treetop height in the wake of a thunderstorm or to hawk insects fleeing from a forest fire or fired cultivation clearing. Drinks at rivers and pools in the evenings, several birds swooping down at a tangent simultaneously, 'leaving a series of longitudinal splashes on the surface like a shoal of flying fish taking wing' (F. N. Betts). Roosts at night in colonies clinging to roughnesses within the hollow boles of lofty ancient trees. Owing to its sustained speed and vast cruising radius, makes sporadic fleeting appearances in distant areas in the course of the day's foraging, causing some confusion as to its local status.

FOOD. Flying insects, mainly beetles (Coleoptera), bugs (Hemiptera), grasshoppers (Orthoptera), and ants and bees (Hymenoptera).

VOICE AND CALLS. Loud, shrill 'screams', frequently uttered in flight, as in 688.

BREEDING. Hitherto recorded only in Kerala. Season, February to April. Nest, a depression in the earth and debris accumulated at the base, within the hollow boles of lofty over-mature trees such as *Valeria indica*, lined with dry leaves and straw — in humid forest. Entrance to 'chimney' provided by a natural or woodpecker hole often up to 15 metres above ground level. Normally only a single nest, or two or three, within each bole, not colonially. Eggs, 3 or 4, rarely 5, broad, elliptical, pure porcelain white becoming stained and discoloured during incubation. Average size of 100 eggs 30.7 × 22.2 mm (Baker). Share of the sexes in the domestic chores, incubation period, and other facets of breeding biology unknown.

MUSEUM DIAGNOSIS. See Key to the Species; for details of plumage Baker, loc. cit.

	Wing	Bill (from skull)	Tarsus	Tail (to tip of spines)
♂ ♀	188-200	13-16	16-18	54-60 mm (Baker, HW, SA)

COLOURS OF BARE PARTS. Iris brown. Bill horny black; mouth greyish pink. Legs and feet greyish pink; claws horny brown.

MISCELLANEOUS. *Ectoparasites*. 'Some infested with a large flat tick nearly one-third inch long [species?], over 30 taken from one bird clinging to bases of stiff tail-feathers under lower tail-coverts' (A. L. Butler, 1899, JBNHS 12: 563).

'Infested with a parasite very like common house bug (*Cimex* sp.?) in appearance and smell' (H. R. P. Carter, 1873, SF 1: 473).

692. Whiterumped Spinetail Swift. *Chaetura sylvatica* (Tickell)

Chaetura sylvatica Tickell, 1846, Jour. Asiat. Soc. Bengal 15: 284 (Central India, restricted to Maunbhum by Whistler & Kinnear, 1935, JBNHS 38: 33)

Baker, FBI No. 1606, Vol. 4: 344

Plate 56, fig. 1

LOCAL NAME. *Sārāppākshi* (all swifts — Malayalam).

SWIFTS

39

curved needle-sharp claws for clinging to rough vertical surfaces. Mouth very wide and deeply cleft. No rectal bristles. Represented by six species within our limits. (See David Lack, 1956, 'The species of *Apus*', *Ibis* 98: 34-62.)

693. *Apus melba melba* (Linnaeus)

Hirundo Melba Linnaeus, 1758, Syst. Nat., ed. 10, 1: 192 (Gibraltar)

Baker, FBI No. 1589 (part), Vol. 4: 324

Plate 56, fig. 12

LOCAL NAMES. *Bādi ābābel* (Hindi); *Pāhādi ābābelo* (Gujarati).

SIZE. Bulbul +; stouter. Length c. 22 cm (8½ in.).

FIELD CHARACTERS. As for 694, q.v. A large sooty brown swift with white underparts and a brown pectoral band across breast. Sexes alike. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Recorded as a fairly common summer visitor (April to September) to Baluchistan in the Quetta neighbourhood, Kach, Ziarat, Chagai; as passage migrant on the Afghan frontier (Kohat, Chitral, etc.) from February to May and again in August-September. Winter specimens in BNHS collection from Saurashtra (Gujarat) and Mt Abu. Capricious season- and weather-dependent movements of Alpine Swifts, the vast radius they cover in the course of their daily foraging, and paucity of material to qualify sight records, make the status of the races, particularly of this one, rather enigmatic.

EXTRALIMITAL. 'Breeds in SE. Europe north to the Pyrenees and the Alps; Asia Minor, the Crimea, the Caucasus, Transcausia, Turkestan... Winter quarters not known but recorded from Arabia, Uganda, and Damaraland and as a migrant in the Algerian Sahara' (Peters).

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 694, q.v.

BREEDING. Extralimital; not definitely recorded in our area, but probably breeds in the higher mountains of Baluchistan (W. Pakistan).

38

APODIFORMES

SIZE. Sparrow —; same as House Swift. Length c. 11 cm (4½ in.).

FIELD CHARACTERS. A small forest swift, black above with a broad white rump-band. Below, chin, throat, and breast greyish brown passing into white on lower abdomen and under tail-coverts. Sexes alike. Under aspect of wings in flight blackish. General effect very like House Swift (703) but white belly in addition to rump-patch diagnostic.

STATUS, DISTRIBUTION AND HABITAT. Resident, but patchy and local, though quite abundant in certain localities. Also subject to considerable wandering; movements imperfectly understood. The lower Himalayas in Garhwal, Kumaon, and Sikkim (possibly continuous). Cachar (Assam), Manipur, Sylhet (E. Pakistan), W. Bengal, Chota Nagpur, Madhya Pradesh (west to Seoni and Chanda, in Maharashtra, c. 79-80°E. long.); the Western Ghats strip from about Goa and N. Kanara (c. 15°N. lat.) southward through W. Mysore, W. Tamil Nadu, and Kerala. Not in Ceylon or Andaman Is. Affects evergreen and moist-deciduous biotope; from plains level to c. 1700 m in the Himalayas, somewhat lower in the peninsular ranges.

GENERAL HABITS. Keeps in loose rabbles of 12 to 50 birds or so, hawking insects all day above forest or river valleys, and over grassy hilltops and hill cultivation clearings, but may turn up almost anywhere in forested country. Roosts at night in colonies, clinging within the hollow boles of rotten trees, the birds popping in and out through natural or barbet holes that provide entrance and exit.

FOOD. As in 691, chiefly flying beetles and bugs.

VOICE AND CALLS. A twittering chick-chick like House Swift's uttered on the wing; rendered also as a 'rapidly-repeated swicky-sweetzy' (Nichols).

BREEDING. Up to the present known only from the Western Ghats area. Season, February to May, chiefly March and April. Nest, a shallow half-cup composed of small lengths of thin dead twigs cemented together with the bird's saliva, without any lining, attached bracket-wise inside a hollow rotten tree-trunk from half a metre to 14 metres or so above the ground. Boles of dead Fishtail palms (*Caryota urens*) are favourite sites. Only a single nest or a couple normally found within the same 'chimney'. Eggs, 3 to 5, pure white, long blunt ovals, closely resembling those of *Collocalia*. Average size of 60 eggs 17.5 × 12.1 mm (Baker). Incubation period, and other facets of breeding biology, unknown.

MUSEUM DIAGNOSIS.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀ (107)	112-116	c. 7-8	c. 8-9	34-37 mm (Baker, HW, SA)

Weight 1 ♂ 13 g (SA).

COLOURS OF BARE PARTS. Iris brown. Bill blackish brown; mouth greyish pink. Legs and feet pinkish brown; claws blackish brown.

Genus *Apus* Scopoli

Apus Scopoli, 1777, Intr. Nat. Hist.: 483. Type, by tautonymy, *Hirundo apus* Linnaeus

Wings long, narrow, and pointed. Tarsus short and thickly feathered; all four toes bare and directed forwards, but first or hind toe reversible; equipped with

40

APODIFORMES

Apus melba

■ Breeding range 1 *A. m. melba* (693). 2 *A. m. rubifuga* (694). 3 *A. m. bakeri* (695).

694. *Apus melba rubifuga* Koelz

Apus melba rubifuga Koelz, 1954, *Contrib. Inst. Regional Exploration*, No. 1: 25 (Rathi, Kumaon)

Apus melba drabata Abdullahi, 1963, *Journ. Bom. nat. Hist. Soc.* 62: 156 (hills and ghats near Bombay)

Baker, FBI No. 1589 (part), Vol. 4: 324

LOCAL NAMES. As for 693. *Sārāppākshi* (for all swifts — Malayalam).

SIZE. Bulbul +; stouter. Length c. 22 cm (8½ in.).

FIELD CHARACTERS. A large streamlined sooty brown swift with very long, narrow, pointed wings, and slightly forked tail. Underparts white, with a brown pectoral band across breast; this, together with brown

SWIFTS

41

under tail-coverts and brown-and-white underside of bow-shaped wings diagnostic in flight. Sexes alike.

Young (immature) has more definite whitish edging to the feathers of the brown parts, especially on the wings, breast-band, and under tail-coverts.

STATUS, DISTRIBUTION and HABITAT. Resident, but subject to seasonal local migration (chiefly during the monsoon) in addition to very extensive and wide-ranging daily foraging peregrinations. Movements not yet worked out. From c. 2200 m up in the Himalayas west to east (including Nepal, Sikkim, Bhutan, and NEFA) southward through the peninsula to Rameswaram I. and Kanyakumari; from Sind eastward to Assam and E. Pakistan. Chiefly based on hilly country with crags and precipices and old forts, but liable to make unpredictable fleeting appearances almost anywhere at any time. A vast colony inhabits the gigantic cliffs flanking the Jog Falls in Mysore, sharing the fissures and crevices with blue rock pigeons, the birds dwarfed to a swarm of midges as they hurtle around the valley in this Brobdingnagian setting.

GENERAL HABITS. Keeps in loose flocks or rabbles on the wing all day, dashing about at great speed hawking insects high up in the air over grassy or forested hillsides and precipitous cliffs and gorges, and shooting round the contours with a loud swish of the wings. Descends lower in overcast drizzly weather or in the wake of a thunderstorm, and to hawk insects fleeing from a forest fire or burning grassland or clearing. Shares the honours for speed with the larger Spinetails, as all who have tried to shoot specimens will readily concede! Roosts at night in clefts and fissures of rock-scarps, clinging almost vertically to the rough surface with both feet. Has the characteristic habit of swifts of 'balling' up in the sky at sunset, often till well into the dark, in a close-packed rabble, wheeling and tumbling playfully to the accompaniment of shrill screams — the whirling mass moving hither and thither as if wafted by the wind, gradually disappearing from sight. On clear wintry evenings has been observed (SA) hawking at treetop height before sunset, rising higher and higher as the sun sank lower and below the horizon, evidently following insect prey into the warmth of the sunshine lingering in the upper air. The birds drink regularly at ponds or streams, a party skimming over the water with butterfly-like quivering of the wing-tips above the back, 'feathering' the surface from time to time as they scoop the draughts.

FOOD. Largely flies (Diptera), ants (Hymenoptera), beetles (Coleoptera) and bugs (Hemiptera) — all taken on the wing. Among the last, *Agnoscelis nubila* Fb., crammed in gullets and stomachs of specimens, has been specifically identified.

VOICE and CALLS. Short, shrill tremulous 'screams' 'chee-chee' etc. chiefly while balling in the air. Twittering noises while roosting (and nesting?) in fissures of cliffs.

BREEDING. Definitely known only in NW. Himalayas (Murree, Kashmir), Saptashring (Nasik dist., Maharashtra) and Gersoppa or Jog Falls (Mysore) but on circumstantial evidence, or putatively, also nests in many places elsewhere in the Western Ghats and peninsular hills with suitable rocky crags and precipices. Season, in the Himalayas evidently May-June; in

SWIFTS

43

visits the lowland tanks at certain seasons for drinking purposes' (Phillips). Subject to considerable erratic movements, and the Ceylon and South Indian populations doubtless wandering into each other's domains in the course of the day's foraging or seasonally.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 694, q.v.

BREEDING. No nests actually taken in Ceylon, but strong circumstantial evidence of breeding in the rock precipices among the hills of the Central Province, Uva and Sabaragamuwa (W. E. Wait, G. M. Henry). Season, c. March-May.

MUSEUM DIAGNOSIS. Smaller and darker even than *A. m. nubifuga*, the wing given by the describer as 190-195 mm. However, 2 ♂♂ from Ceylon in the British Museum collection, though very dark in coloration, have wing 201-207 mm (HW). See Note, p. 42.

COLOURS OF BARE PARTS. As in 694.

696. Swift. *Apus apus pekinensis* (Swinhoe)

Cypselus pekinensis Swinhoe, 1870, Proc. Zool. Soc. London: 435 (Pekin, China) Baker, FBI No. 1590, Vol. 4: 326 Plate 56, fig. 6

LOCAL NAMES. None recorded.

SIZE. Bulbul —; length c. 17 cm (6½ in.).

FIELD CHARACTERS. A typical swift with long, narrow, bow-shaped wings and moderately forked tail. Uniformly dark brown or sooty black, with whitish chin and throat and sometimes with a few pale crescentic marks on belly. Sexes alike.

Young (immature) has the forehead whitish. Feathers of crown, belly, under tail-coverts, and leading edge of wing, margined with whitish.

STATUS, DISTRIBUTION and HABITAT. Breeding visitor to N. Baluchistan ('commonest swift near Quetta'), and northward along the Afghan frontier to Chitral and Gilgit. Also Ladakh, Balistan, Kashmir and Himachal Pradesh (?); normally between c. 1500 and 3300 m, sometimes higher; obtained by Meinertzhagen in the Changchenmo, 14,800 ft (c. 4500 m) and observed at Tutyalak in the Indus Valley (Ladakh), 18,800 ft (c. 5730 m) in July, the latter presumably a foraging party from below; possibly partly resident in some of these areas. Wintering in small numbers in N. India; recorded from N. Cachar in Assam (Baker — regular or casual?), and stragglers from Andaman Is. (?), Maldives (Phillips), Saurashtra (Lavkumar, subspecies?).

Extralimital. 'Breeds in Cyprus, Asia Minor, Persia, Turkestan, NW. Mongolia and S. Manchuria, south to Palestine, Baluchistan, the Himalayas, Kansu and Chihili. Winters in India and in eastern Africa from the White Nile to the Kalahari Desert and Transvaal' (Peters).

MIGRATION. Arrives in its summer (breeding) quarters — N. Baluchistan, Chitral — beginning to mid April; leaves in September.

GENERAL HABITS. Keeps in parties and scattered flocks, sometimes large rabbles, spending the entire daylight hours on the wing, hawking insects high up in the air or swooping in their pursuit close to the ground. In the early mornings, but more usually at dusk, indulges in the characteristic

42

APODIFORMES

Mysore December to February. Nest, a half-saucer shaped structure of straw and feathers agglutinated with the bird's saliva, stuck bracket-wise on a vertical rock face within a fissure in a rocky cliff; alternatively, a concave pad of the same material placed on a horizontal ledge in similar situations. Nest material (straw and feathers) chased and collected in mid-air as it floats on wind eddies. Eggs, normally 3, sometimes 2, rarely 4. Pure white, long narrow ovals measuring c. 31 x 19 mm. Both sexes evidently share incubation; period c. 19-20 days (in the nominate race — Witherby). Copulation takes place in the air, the male and female with open motionless wings whirling round and round as one unit parachuting through space for 30 metres or so, then separating to fly away individually; evidently also at nest.

MUSEUM DIAGNOSIS. Differs from the nominate form in being somewhat smaller and darker, with a wider pectoral band and smaller throat-patch.

MEASUREMENTS

	Wing	Bill (from skull)	Tail	
			central	outer
♂♂	202-212	14-16	59-63	73-79 mm
♀♀	198-206	14-16	58-61	72-76 mm

(HW, SA)

COLOURS OF BARE PARTS. Iris dark brown. Bill black. Legs and feet blackish purple.

NOTE. Peninsular Indian birds (*nubifuga*) are normally darker than *melba* of southern Europe, but at the same time they are matched by some Himalayan examples considered to be migrants of the nominate form. A parallel case exists between the still darker birds of Ceylon (*bakeri*) and those of peninsular India. Allowing for the normal operation of Bergmann's Rule (decrease in size from north to south), the size differences are also not sufficiently clear-cut or suggestive for unequivocal racial identification of individual specimens when the races occur together. Our knowledge of the spatial foraging movements of these wide-ranging swifts is as yet too nebulous for a satisfactory evaluation of the races and their status within our limits.¹ Only a methodical collection of actually breeding birds from proved nesting sites can help to elucidate the position.

695. *Apus melba bakeri* Hartert

Apus melba bakeri Hartert, 1928, Novit. Zool. 34: 363 (Cattion Estate, 4500 ft, Ceylon) Baker, FBI No. 1589a, Vol. 8: 680

LOCAL NAME. *Wzhi lilihiyā* (Sinhala).

SIZE. Bulbul +; stouter. Length c. 22 cm (8½ in.).

FIELD CHARACTERS. As for 694, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident in Ceylon. 'Plentiful, but locally distributed, in the hills to altitudes of over 7000 ft (c. 2100 m);

¹ See the communication by A. H. H. 1965 / IRNH 62: 153-60 recording the occurrence of this swift, *A. m. derabtalai*,

APODIFORMES

44

Apus apus

communal 'balling' — a more or less compact rabble whirling round and round in the air, the disorderly revolving mass moving rapidly away as if wafted by the breeze; or mounting ever higher in the sky to disappear from view; this to the accompaniment of shrill lively 'screams'. Flight very fast, but less so than Alpine or Spinetailed, with rapid quivering wing-beats, punctuated by spells of rocket-like gliding on stiffly open wings, with slight tilts and turns of the body and swishing wheeling movements. As summer visitor usually seen about cliffs in the mountains, roosting and nesting in rock fissures; but in extralimital areas commonly takes the place of House Swift (703), hawking over urban localities and normally nesting in buildings.

Left foot, x c. 1

FOOD. As in 694 (q.v.) and other swifts — insects, chiefly Coleoptera, Hemiptera, Diptera, and Hymenoptera.

VOICE and CALLS. 'A long-drawn harsh screaming *sweet or sweet*' (Witherby) uttered on the wing; in a discordant chorus when balling. Aerial nuptial (?) chases, but involving a trio instead of a pair commonly observed; its significance not fully understood. Copulation commonly takes place in mid-air as in Alpine Swift.

BREEDING. Owing to inaccessible cliff-sites apparently no nests taken in our limits, but circumstantial evidence of breeding in NW. Pakistan and Kashmir adequate. Season, May-June. Nest, presumably as in the nominate European form, a shallow cup of bits of straw, feathers and other rubbish hawked in the air and agglutinated together with the bird's saliva. Built in colonies on ledges within fissures of rock. Eggs, normally 3, sometimes 2 or 4, dull white, elongated ovals, c. 25 x 16 mm; laid at c. 48-hour

SWIFTS

45

intervals; incubation period 18-19 days. (For details of breeding biology of nominate *apus*, see David Lack, 1956, *Ibis* 98: 606-19.)

MUSEUM DIAGNOSIS. Similar to nominate *apus* but paler. Body plumage more brownish less blackish; wing feathers (especially secondaries) more greyish brown less blackish; forecrown paler, the pale area of throat more extensive and whiter (Vaurie, 1965). For description of plumages and structure etc. of the nominate race see Witherby, 1938, 2: 244-8.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	160-180	c. 8	c. 10	66-77 mm (Baker)

Wing ♂ ♀ 165-176 mm (Hartert).

COLOURS OF BARE PARTS. Iris dark brown. Bill black. Legs and feet purplish brown.

697. Pallid Swift. *Apus pallidus pallidus* (Shelley)

Cypselus pallidus Shelley, 1870, *Ibis*: 445 (Egypt)

Cypselus marinus A. & L. Brehm, 1855, *Vogelfang*: 46 (North Africa and southern Europe, Suit, Egypt). Not *Cypselus marinus* Voigt, 1831, which = *Cypselus ferrus* (Lichtenstein)

Baker, FBI No. 1591, Vol. 4: 327

Plate 56, fig. 5

LOCAL NAMES. None recorded.

SIZE. Bulbul —; length c. 17 cm (6½ in.).

FIELD CHARACTERS. A typical swift with slender streamlined body, long, narrow bow-shaped wings, and moderately forked tail. Very like 696 but pale mousy- or hair-brown instead of blackish above, and even paler below (the feathers narrowly fringed whitish); whitish throat-patch diffusing at edges into surrounding brown. Sexes alike.

Pale coloration readily distinguishes it on the wing from Eastern Swift.

Young (immature) more squamated white and brown on underparts.

STATUS, DISTRIBUTION AND HABITAT. A desert form occurring only in W. Pakistan as a scarce and apparently irregular winter visitor. Recorded from coastal Makran and Sind (Karachi, Hyderabad).

Extralimital. Resident in Egypt, Palestine, Persia, S. Arabia and Sind; southern Sahara (Air) — Peters. Locally sympatric with 696.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 696, q.v.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	162-170	c. 7	c. 9	65-70 mm (Baker)

24 ♂ ♀ from Egypt: Wing 164-171 mm (Meinertzhagen).

COLOURS OF BARE PARTS. Iris brown. Bill black. Legs and feet dull purplish brown.

SWIFTS

47

BREEDING. Only known from the Khasi Hills, Assam, there restricted to the rocky cliffs and deep gorges around Cherrapunji facing the Sylhet plains — an area reputed for the world's heaviest rainfall. *Season*, end March to end April. *Nest*, similar to the Eastern Swift's (696), a shallow cup of grass, feathers, etc. agglutinated together with the bird's saliva and on to ledges of rock within fissures in cliffs — colonially. *Eggs*, 2 or 3, occasionally 4, white, long blunt ovals. Average size of 50 eggs 26.0 × 16.3 mm (Baker). Both sexes reported to partake in nest-building and feeding the young. Share in incubation, and incubation period, undetermined.

MUSEUM DIAGNOSIS. The squamated effect of underparts is produced by white margins to the dull black feathers. Amount of this white very variable in adults (age-dependent?).

Nestling (partly fledged) has the white feather-margins on underparts very broad, and traces of pale edges to the scapulars, back, and wing-coverts (Baker).

For a review and discussion of the taxonomical status of *A. acuticauda* and *A. pacificus*, of which he considers the former to be a subspecies, see D. Lack, 1956, *Ibis* 98: 36-8; *Auk* 73: 15 and *passim*.

MEASUREMENTS

699. *Apus pacificus pacificus* (Latham)

Hirundo pacifica Latham, 1801, *Index Orn.*, Suppl., lviii (new Holland = New South Wales *apud* Mathews); the *terra typica* has been fixed as the vicinity of Vladivostok by Dominiewski, 1933, *Acta Orn. Mus. Zool. Polonica* 1: 80

Baker, FBI No. 1593, Vol. 4: 329

Plate 56, fig. 7

LOCAL NAMES. None recorded.

SIZE. Bulbul —; length c. 18 cm (7 in.).

FIELD CHARACTERS. A deeply fork-tailed swift, blackish brown above with a broad white rump-patch; squamated or mottled black and white below, with whitish chin and throat. Sexes alike.

APODIFORMES

Apus pallidus

■ Breeding range

698. Darkbacked Swift. *Apus acuticauda* (Jerdon)

C. (cypselus) acuticauda [sic] 'Blyth (MSS)' = Jerdon, 1864, *Bds. India* 2: 870. With reference to Vol. 1: 177, No. 99 (Nepal). Misprint for *acuticauda*.

Cypselus acuticauda Blyth, 1865, *Ibis*: 45 (Nepal)

Apus acuticauda rupchandii Koelz, *Contrib. Inst. Regional Exploration*, No. 1: 26

(Blue Mountain, Lushai Hills)

Baker, FBI No. 1592, Vol. 4: 327

Plate 56, fig. 9

LOCAL NAMES. None recorded.

SIZE. Bulbul —; length c. 17 cm (6½ in.).

FIELD CHARACTERS. As of 696, q.v.; also with moderately forked tail.

Adult. Above, deep metallic black including rump. Below, chin and throat white streaked with black; under tail-coverts black; rest of underparts black squamated with white. Sexes alike.

In high overhead flight when rump not visible easily confused with white-rumped *A. pacificus* (699), which likewise has squamated underparts. **STATUS, DISTRIBUTION AND HABITAT.** Enigmatical. The type of the species was obtained in Nepal where not met with since. A single specimen shot at Port Blair on 30 July; its occurrence in the Andamans at that date considered very remarkable by Hume (1874, *SF* 2: 156). Known as breeding bird only in the Khasi Hills (Cherrapunji); presumably also breeds in Mizo hills.

GENERAL HABITS. Similar to 696 and 699, q.v. Reported by Baker to keep in close proximity of its nesting cliffs while breeding, not making the far-ranging feeding forays of other swifts, and thereafter to disappear till the following nesting season.

APODIFORMES

48

× c. ½
(After Hartert)

Easily confused with *A. acuticauda* (698) in flight, but white rump (v. black) diagnostic.

STATUS, DISTRIBUTION AND HABITAT. From specimens collected, evidently a winter migrant or wanderer to Assam, Nagaland, Manipur, and Mizo (?); but status unclear owing to possible confusion in sight records with the other races, and even with *A. acuticauda*.

Extralimital. Breeds in eastern Asia from the western Altai and Yakutsk east to Kamchatka and Korea; northern Mongolia and eastern China westward to Kansu and Szechuan. (For details see Vaurie, 1965, 2: 654.)

GENERAL HABITS, FOOD, VOICE AND CALLS. As in other swifts, c.g. 703.

BREEDING. Extralimital.

Apus pacificus

■ Breeding range 1 *A. p. pacificus* (699). 2 *A. p. leucorhynchus* (700). 3 *A. p. kerrii* (701).

MUSEUM DIAGNOSIS. See Key; for details of plumage, Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail (outer)
♂ ♀	168-195	c. 7	c. 10-11	72-81 mm (Baker)

For eastern Chinese birds La Touche, 1931-34 (2: 91) gives:

♂ ♂	182-193	c. 7	c. 13	80-90 mm
♀ ♀	170-189			74-83 mm
				(depth of fork 23-33 mm)

SWIFTS

49

COLOURS OF BARE PARTS. Iris dark brown. Bill black. Legs and feet dark purplish black (Baker).

700. *Apus pacificus leuconyx* (Blyth)

Cypselus leuconyx Blyth, 1845, Jour. Asiat. Soc. Bengal 14 (1): 212 (Calcutta) Baker, FBI No. 1595, Vol. 4: 331

LOCAL NAMES. None recorded.

SIZE. Sparrow ±; length c. 15 cm (6 in.).

FIELD CHARACTERS. As of 699, q.v. On a casual view in flight would pass for a House Swift (703), but for the forked tail. See Key to the Species.

STATUS, DISTRIBUTION AND HABITAT. Status uncertain. Occurs in the breeding season along the outer Himalayas between c. 600 and 3600 m from Kashmir to NEFA including Nepal, Sikkim and Bhutan. Definitely known to breed round Murree, Mussoorie, Naini Tal and in the Khasi Hills (Shillong). Possibly also breeds elsewhere in the Himalayas and other hills south of Brahmaputra river, Manipur, Mizo and E. Pakistan hills. Movements in non-breeding season capricious and unpredictable even in areas of known abundance, e.g. northeastern Assam where 'flocks of hundreds one afternoon then not another bird to be seen again maybe for a week' (Hume). Easily missed in fine weather when hawking at great heights; more in prominence as forerunner of a storm and in overcast drizzly weather when it descends to lower levels, often seen in company with Alpine and House Swifts and swallows. Wanders far and wide in the Peninsula; has been reported from such far-flung localities as Andhra (Mulug), Saurashtra, Bombay City, Konkan, North Kanara (Karwar — 'large flocks occasionally during the rains' — Davidson, JBNHS 12: 47) and Malabar.

GENERAL HABITS, and FOOD. As in other swifts; during daytime almost ceaselessly on the wing hawking insects. Flying termites listed among stomach contents.

VOICE and CALLS. Not specifically described.

BREEDING. Season, apparently long-drawn, c. April to July. Nest, a half-cup of grass, bits of leaf, etc. cemented together with inspissated saliva, stuck against a slanting rock-face within a fissure in a high cliff; usually difficult of access. Built in small colonies or clusters. Utilizing nest of martin (*Delichon nipalensis*) has been recorded (Whymper). Eggs, 2 or 3, white, narrow, elongated, typical of swifts. Average size of 11 eggs 22.7 × 15.0 mm (Baker). Share of the sexes in the domestic chores, and incubation period, unrecorded.

MUSEUM DIAGNOSIS. Differs from the nominate race (699) in being smaller and darker with a narrower white rump.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail (outer)
♂ ♀	147-160	c. 7	c. 11	65-71 mm (Baker)

COLOURS OF BARE PARTS. Iris brown. Bill black. Legs and feet purplish brown or purplish black (Ticehurst).

SWIFTS

51

Extralimital. Morocco, Algeria, Tunisia and southern Sahara (Air); Syria, Palestine, Transcaspia and Persia (Peters). For details of range see Vaurie, 1965, 2: 649.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 703.

BREEDING. Season ill-defined; practically throughout the year excepting the coldest months. Nest and site as in 703. In Sind Ticehurst found small colonies under ledges of cliffs out in the desert (*Ibis*, 1923: 35). Eggs, 2, as of the Indian House Swift. Average size of 20 eggs 22.4 × 14.2 mm (Baker).

MUSEUM DIAGNOSIS. Very similar to nominate *affinis* (703), also with short tail and a distinct contrast between colour of head and nape and colour of mantle. It is merely a larger and paler form of *affinis*, the palest parts of the head, namely the forehead and a short connected superciliary streak, tending to white. But recognizable with certainty only if a series of Palestine birds is compared with a series from south and central India. Individual specimens from W. Pakistan and NW. India are not always distinguishable in colour either from *galilejensis* or *affinis*, and moreover the complete gradation in size often makes subspecific allocation impossible. For a discussion see Whistler (JBNHS 38: 30), who suggests that under the circumstances *galilejensis* may be removed from the Indian list.

MEASUREMENTS

	Wing	Tail
Palestine birds		
♂ ♀	132-138	40-46 mm
Punjab birds		
9 ♂♂	125-134	39-44 mm
13 ♀♀	127-133	38-43 mm (HW)

703. *Apus affinis affinis* (J. E. Gray)

Cypselus affinis J. E. Gray, 1830, in Gray and Hardwicke's Ill. Ind. Zool. 1(2), pl. 35, f. 2 (No locality = Ganges) Baker, FBI No. 1596, Vol. 4: 332 Plate 56, fig. 4

LOCAL NAMES. *Ābābel*, *Bābelā* (Hindi); *Pākoli* (Marathi); *Ābābelo* (Gujarati); *Sārāppākūhi* (Malayalam).

SIZE. Sparrow; length c. 15 cm (6 in.).

FIELD CHARACTERS. A small smoky black swallow-like bird with conspicuous white rump, white throat, short square tail, and long narrow sickle-shaped wings. Usually seen in scattered rabble-like flocks dashing about in the air at great speed all day long, hawking insects over towns and villages, often in company with swallows. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Resident and common; in some areas locally migratory in the coldest months. All India from the Punjab to West Bengal, and south through the entire Peninsula with the possible exception of Kerala where the birds are

× c. 1

50

APODIFORMES

701. *Apus pacificus kanoi* (Yamashina)

Micropus pacificus kanoi Yamashina, 1942, Bull. Biogeogr. Soc. Japan 12 (2): 72 (Botel Tobago)
Apus pacificus salimalii Lack, 1958, Jour. Bombay nat. Hist. Soc. 55: 160-1 (Molo, Chu Valley, SE. Tibet)
Baker, FBI No. 1593 (part), Vol. 4: 329

LOCAL NAMES. None recorded.

SIZE. Bulbul —; length c. 18 cm (7 in.).

FIELD CHARACTERS. As of 699. See Key and Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Not yet recorded but may occur in NEFA since it breeds in adjacent southeastern Tibet.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 699 and other swifts.

BREEDING in the lower Tsangpo Valley (SE. Tibet) at c. 3500 m in summer under the eaves of the larger houses and also in the lofty stone defence towers characteristic of the 'villages' (Ludlow, 1944).

MUSEUM DIAGNOSIS. As large as nominate *pacificus* (699), but almost identical with *leuconyx* in the other characters, viz. darker upperparts, decidedly narrower white rump, and much narrower white tips to feathers of underparts. Thus separable from *pacificus* by colour and from *leuconyx* by size.

MEASUREMENTS. Wing 5 ♂♂ 173-179 (mean 176) mm (Lack).

COLOURS OF BARE PARTS. As in 699.

702. *Apus affinis galilejensis* (Antinori)

Cypselus Galilejensis? Antinori, 1855, Naumannia: 307 (Sea of Galilee, Palestine) Baker, FBI No. 1597, Vol. 4: 334

LOCAL NAMES. *Ābābel*, *Bābelā* (Hindi); *Chāmro* (Sind).

SIZE. Sparrow; length c. 15 cm (6 in.).

FIELD CHARACTERS. As of 703, q.v. See Key to the Subspecies and Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident and common in West Pakistan [Baluchistan (Quetta), Sind, W. Punjab (Dera Ghazi Khan)] except in the coldest months, c. November to February, when scarce or absent; presumably migrating then to warmer parts in peninsular India. But see remarks under Museum Diagnosis.

52

APODIFORMES

darker and seem more akin to the Ceylon race. Plains and up to c. 2000 m in the Himalayas and peninsular hills. Affects the neighbourhood of urban habitations, crumbling old forts and ruins, and cliffs.

Apus affinis

- Breeding range 1 *A. a. galilejensis* (702). 2 *A. a. affinis* (703).
3 *A. a. nipalensis* (705). 4 *A. a. singalensis* (704).
5 *A. a. subfuscatus* (706). 6 *A. a. abyssinicus* (RE).
7 *A. a. bannermani* (RE).

GENERAL HABITS. Gregarious, predominantly aerial and rather parochial. In small parties and loose rabble-like flocks of up to 50 or a hundred birds or so; sometimes much larger aerial congregations or 'clouds', presumably then on local migration. Spends most of the day on the wing, usually keeping within a wide perimeter of the nest colonies or 'villages', the birds shooting into the nests from time to time as they circle around, sometimes more or less all in a body. Flight very swift (whence the name) — a few rapid quivering beats of the stiffly held narrow wings, followed by swooping glides, with much agile wheeling and twists and turns in pursuit of midges and other aerial insects. Shrill musical twittering squeals often accompany these manoeuvres. Flocks commonly seen disporting themselves in the evenings, 'balling' up in the sky obviously for fun, uttering shrill joyous screams; the milling rabble gradually wafting away in the distance or mounting higher and higher till almost out of sight. In a strong head wind, the wings are often turned steeply downwards like a sloping roof, the bird thus remaining suspended in mid-air for split seconds or even drifted backwards by the current but clearly enjoying the sport. Very sensitive to low temperatures, the majority, especially in the northern parts, abandon their breeding areas for three

SWIFTS

53

or four of the coldest months. The paucity of tiny flying insects up in the frigid atmosphere may, however, be an important contributory factor.

Courtship. Nest-based birds frequently disport themselves of an evening — pairs or trios flying at speed in close formation, almost wing to wing, in and out of verandas etc. below the nest clusters, twittering shrilly the while. The flight now is a butterfly-like fluttering with the wings raised in a 'V' above the back, only their tips vibrating rapidly. The exact significance of these triangular 'chases' is not understood.

Food. Midges (Diptera), tiny flying bugs and beetles (Hemiptera, Coleoptera), winged ants (Hymenoptera), air-borne spiders (Araneida), etc. all captured in mid-air.

voice and CALLS. Shrill spirited musical screams, uttered chiefly on the wing. Rendered as 'a very rapid *siksiksiksik—sik-sik—siksiksiksik* all pitched on the same note' and variants of this (M. D. Lister). A shrill *chuck-chrrrr* started by one bird in the roost and promptly taken up as a chorus by its neighbours, sometimes passing as a wave, or as repeated waves, through the entire colony. Usually heard early in the morning before the birds leave their dormitory; sometimes also after retiring into it at dusk (A. Razack).

BREEDING. *Season*, practically all year except the coldest months, namely c. November to February, the peak periods (apparently two) varying locally. *Nest*, basically a globular untidy mass of grass and feathers cemented together with the birds' saliva, very variable in shape. Usually attached under the eaves of houses or in the angle of the ceiling and wall, or under an arched gateway, bridge and the like. Built in colonies, small or large, the nests stuck in disorderly fashion one upon another in a conspicuous conglomerated mass; each has a separate entrance, in some cases merely a slit between the wall and the nest. Old mosques and ruins are favoured, and the so-called 'nest villages' are often sited in the midst of congested noisy bazaars with people and traffic moving within a few metres of the birds flying in and out. The nests are repaired and used year after year, and where unmolested the 'villages' tend to become traditional, some being known to be occupied for over eighty years. In areas of all-year residence nests used as dormitories during non-breeding season. Occasionally single nests are built, or a pair of swifts will usurp the mud nests of Wiretailed, Redrumped and Cliff Swallows, adapting them to their own use by a copious lining of tell-tale feathers. *Eggs*, 2 or 3, rarely 4, pure white longish ovals; laid at intervals of 2 or 3 days, in some cases even up to 7 days. Average size of 100 eggs 22.2 × 14.2 mm (Baker). Both sexes take part in building the nest, incubation (?) and tending the young, who leave the nest between 37 and 43 days of hatching. Incubation period 18–26 days (Razack)¹. Brooding begins with the first egg, often resulting in considerable disparity in the growth of the nestlings. They are fed on boluses of tiny insects brought in the parents' gullet. All nest material is also collected in the air.

MUSEUM DIAGNOSIS. Crown light brown paling to greyish on forehead and forehead; upper tail-coverts and tail dark brown. Tail slightly forked when freshly moulted. For description of plumage see Baker, loc. cit.; for a discussion on the Indian races, Whistler (JBNHS 38: 30); Abdulali (ibid. 62: 523–8).

¹ Razack, K. M. A., 1968. 'Some Observations on the Biology of the House Swift, *Apus affinis* (Gray)'. Ph.D. thesis, M. S. University, Baroda.

SWIFTS

55

FIELD CHARACTERS. As of 703, q.v. See Key to the Subspecies and Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident, subject to seasonal local and altitudinal movements. Nepal, Sikkim, Bhutan and western Assam (Kamrup dist.) to c. 2000 m.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 703.

BREEDING. *Season*, chiefly April to July. Apparently less colonial than *affinis* at least when nesting in buildings; the 'villages' usually smaller, and usurpation of individual swallow nests commoner. Colonies may be larger when sited on cliffs, but this not specifically recorded. Average size of 10 eggs 21.9 × 14.4 mm (Baker).

MUSEUM DIAGNOSIS. Darker than *affinis* with the head all brown, not paling to greyish on forehead or forehead. Upperparts, excepting white rump-patch, sooty black slightly glossed with green.

MEASUREMENTS

	Wing	Tail
16 ♂ ♀	129–139	42–49 mm (Bixwas)

COLOURS OF BARE PARTS. As in 703.

706. *Apus affinis subfuscatus* (Blyth)

Cypselus subfuscatus Blyth, 1849, Jour. Asiat. Soc. Bengal 18 (2): 807 (Penang)
Baker, FBI No. 1599, Vol. 4: 335

LOCAL NAME. *Dao hādi* (Cachari).

SIZE. Sparrow; length c. 15 cm (6 in.).

FIELD CHARACTERS. As of 703, q.v. See Key to the Subspecies and Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident, with the usual seasonal local movements. Assam (excluding Kamrup dist.) to c. 1200 m, south through Nagaland, Manipur, Mizo Hills (?); East Pakistan.

Extralimital. Southern China from Yunnan to Fukien, south to Burma, Malay Peninsula, Thailand and the Indochinese countries. Indonesian islands.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 703.

BREEDING. *Season*, in Assam April to July, chiefly May and June. 'A purely cliff-breeding bird, [in Assam] some of the colonies being of great size, numbering one or even two hundred pairs of birds. . . . The nests on cliffs are nearly all of the strong, well made half-cup type' (Baker). *Eggs* 2 or 3; average size of fifty 22.7 × 14.9 mm.

MUSEUM DIAGNOSIS. Darker than *affinis* with head, tail, and upperparts (except for white rump) all practically black and without contrast. Matches *singalensis* (704) in colour, but is larger on the average and with a longer, slightly forked tail.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	130–142	c. 6	c. 9–10	44–47 mm (Baker)

Outer tail-feathers 4–7 mm longer than the central ones.

54

APODIFORMES

MEASUREMENTS

	Wing	Tail
♂ ♀	122–135	37–44 mm (Baker, HW, HA)

Bill (from feathers) 6–7 mm; tarsus c. 9–10 mm (Baker).

Weight 1 ♂ 21 g (SA).

COLOURS OF BARE PARTS. Iris brown. Bill horny black; mouth pink. Legs and feet pinky brown; claws horny black (SA).

704. *Apus affinis singalensis* Madarász

Apus singalensis Madarász, 1911, Ann. Hist.-Nat. Mus. Nat. Hungar. 9: 420, pl. 16 f. 4 (Ceylon)

Baker, FBI No. 1598 (part), Vol. 4: 334

LOCAL NAMES. *Wēhi līhīmīyā* (Sinhala); *Sārāppākshi* (Malaya); *Forika* (Maldivean).

SIZE. Sparrow; length c. 15 cm (6 in.).

FIELD CHARACTERS. As of 703, q.v. See Key to the Subspecies and Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident; Ceylon and possibly Kerala. Plentiful but locally distributed in all zones throughout the Island to over 1200 m; patchily and rather capriciously in Kerala. Sight recorded in Maldives Is. (Phillips, JBNHS 60: 580); subspecies unconfirmed. Keeps chiefly in the neighbourhood of big rock-masses in the foothills and low country.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 703.

BREEDING. *Season*, April to September, chiefly March to July. Breeding biology as in 703.

MUSEUM DIAGNOSIS. Distinguished from peninsular *affinis* (703) by blacker coloration: head, tail and upper tail-coverts all practically black, almost the same colour as mantle. Rump-patch white as in 703 and other races. Kerala birds are also blacker than *affinis* and evidently belong to the Ceylon population.

MEASUREMENTS

	Wing	Bill (from skull)	Tail
♂ ♀	127–133	11–12	42–45 mm (HW, HA)

Weight 1 ♂ 24 g; 1 ♀ 23 g (SDR).

705. *Apus affinis nipalensis* (Hodgson)

Cypselus Nipalensis Hodgson, 1836, Jour. Asiat. Soc. Bengal 5: 780

(Central region of Nepal)

Baker, FBI No. 1598, Vol. 4: 334

LOCAL NAME. *Bātāsi* (Nepali).

SIZE. Sparrow; length c. 15 cm (6 in.).

56

APODIFORMES

COLOURS OF BARE PARTS. As in 703.

Genus *CYPSIURUS* Lesson

Cypsiurus Lesson, 1843, Echo du Monde Savant, Ann. 10, 2me sem.: 134. Type, by monotypy, *Cypselus ambrasiacus* Temminck = *Cypselus parvus* Lichtenstein

Small swifts with deeply forked tails. Toes arranged in pairs, the 3rd and 4th toes outward, the 1st and 2nd (inner and hind) inward.

CYPSIURUS PARVUS (Lichtenstein): PALM SWIFT

Key to the Subspecies

Paler; depth of tail-fork exceeding 28 mm. *C. p. balariensis*
Darker; depth of tail-fork less than 28 mm. *C. p. infumatus*

707. *Cypsiurus parvus balariensis* (J. E. Gray)

Cyp.(selus) Balariensis [sic] J. E. Gray, 1829, in Griffith's Anim. Kingdom 7: 60 (India, restricted to Calcutta by Baker, 1927, Fauna 4: 336, re-restricted

to Balasore district, north-eastern Orissa, by Ripley, *Synopsis*, 2nd ed., p. 201, 1932)

Cypselus palmorum J. E. Gray, 1830, in Gray and Hardwicke's Ill. Ind. Zool. 1(2), pl. 35, figs. 1a and 1b (No locality = Cawnpore)

Baker, FBI Nos. 1600, 1601, Vol. 4: 336; 338

Plate 56, fig. 13

LOCAL NAMES. *Tādi ābābel*, *Tāchatta*, *Patta duli* (Hindi); *Tāchārāi*, *Bātāsi* (Bengali); *Shimri* (Marathi); *Tād ābābelo* (Gujarati); *Amāttān kātti* (Tamil); *Pānāpākshi*, *Pānākkatti* (Kannada); *Pānāmpākshi* (Malayalam); *Wēhi līhīmīyā* (Sinhala); *Ulavāra kūrūri* (Tamil, Ceylon).

SIZE. Sparrow —; slimmer. Length c. 13 cm (5 in.).

FIELD CHARACTERS. A slim, plain sooty grey swift, with narrow, deeply forked tail. In flight the long slender curving wings reminiscent of a miniature bow with the body set in it for an arrow. Tail-fork very conspicuous when bird banking in flight. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Resident practically throughout our area south of the Himalayas [excluding the range of the eastern *infumatus* (708)] and Ceylon. Patchy in Rajasthan and Gujarat. Absent in West Pakistan. Chiefly plains; locally in the hills to c. 1000 m. Affects open country and cultivation dotted with palm trees. Occurrence everywhere closely associated with palms, especially the *tād* or palmyra (*Borassus flabellifer*), and locally the betelnut palm (*Areca catechu*).

GENERAL HABITS. Gregarious and aerial like House Swift, but usually more scattered; rarely seen in close-packed flocks. Spends the day on the wing hawking insects high up in the air or close to the ground, almost invariably in the proximity of palmyra palms; sometimes a colony may even be based on a single palmyra palm, or a small cluster, with no others for miles around. Flight swift and arrowy with agile twists and turns in pursuit of prey, accompanied by lively twittering screams. This particularly when a party is sporting around the roosting place near sunset. Roosts in furlows on the underside of a downhanging palmyra leaf, clinging in an upright

SWIFTS

57

position. Courtship chases as in House Swift (703), sometimes involving three and even four birds. Copulation in mid-air as in most other swifts.

FOOD. Winged ants and other hymenopterous insects, tiny bugs and beetles (Hemiptera, Coleoptera), etc., taken in the air.

VOICE AND CALLS. A shrill, joyous, triple twittering scream *tititee*, uttered on the wing.

BREEDING. Season, practically throughout the year, the peak periods varying locally. *Nest*, a flimsy half-saucer c. 10 mm deep and 40 mm in diameter, of vegetable down (e.g. *Calotropis*, *Salmalia*, etc.) agglutinated together with the bird's saliva; attached bracketwise within a furrow on the underside of a drooping palmyra frond with the supporting 'apron' of inspissated saliva and feathers stretching upward for c. 8 cm behind the nest like a screen or backdrop. This apron used by growing young to cling to when the cup gets too small to contain them. Nest sometimes built near mid-rib under arching areca frond. *Eggs*, normally 2 occasionally 3, pure white elongated pointed ovals, typical of swifts. Average size of 50 eggs 18.2 × 11.5 mm (Baker). Both sexes take part in collecting floating vegetable down in the air and in building the nest. Share in incubation, and period, unrecorded.

MUSEUM DIAGNOSIS. See Key to the Subspecies.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail central outer
♂ ♀	113-122	7-8	8-9	30-33 60-68 mm (HW, SA)

COLOURS OF BARE PARTS. Iris brown. Bill dark horny brown; mouth pinkish grey. Legs, feet and claws pinkish brown.

708. *Cypsiurus parvus infumatus* (Sclater)

Cypselus infumatus Sclater, 1865, Proc. Zool. Soc. London: 602
(Banjermassing, Borneo)
Baker, FBI No. 1602, Vol. 4: 338

LOCAL NAME. *Dao hadi kashiba* (Cachari).

SIZE. Sparrow —; slimmer. Length c. 13 cm (5 in.).

FIELD CHARACTERS. As of 707. See Key to the Subspecies, and Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident. Assam south of Brahmaputra river, Nagaland, Manipur, Mizo hills, Tripura, East Pakistan. Plains and up to c. 600 m. Sight recorded (subspecies?) in NEFA (Subansiri area) — Betts, JBNHS 53: 411.

Extralimital. Burma, Thailand, and Vietnam; Hainan I. Malay Peninsula, Tambelan Is., Sumatra, Java, Bali, Billiton and Borneo (Peters).

GENERAL HABITS. Similar to 707, but keeps more to open clearings in forest, and is somewhat less dependent on palm trees. In their absence commonly roosts and nests in the thatching of roofs in tribal villages, flying in and out of the houses fearlessly within grabbing distance of the inmates.

FOOD, VOICE AND CALLS. As in 707.

SWIFTS

59

deeply forked tail distinguish it. At rest the tail, narrowed to a spike, projects between the crossed wing-tips.

STATUS, DISTRIBUTION AND HABITAT. Resident; rather patchily distributed and subject to some seasonal local movements. All along the base of the Outer Himalayas (up to c. 1000 m) and throughout the Indian Union except the more treeless parts of Punjab, Rajasthan, and Gujarat (Kutch). Occurs also in Nepal (lowlands, bhabor and dun), East Pakistan, and Ceylon (lowlands and hills to c. 1200 m). Absent in West Pakistan. Affects well-wooded areas of deciduous forest — teak, *Anogeissus*, *Boswellia*, etc. — preferably in broken foothills country.

Extralimital. Extends through Burma south to central Tenasserim, Thailand and the Indochinese countries. Other races in the Indonesian islands.

GENERAL HABITS. Keeps in loose parties of 6 to 8, occasionally larger flocks, wheeling in wide circles hawking insects high above the tree-tops in open deciduous forest, uttering their distinctive calls. Comparatively parochial, seldom wandering as far afield as some other swifts in the course of their foraging. Flight very like Palm Swifts, much slower than is typical of the family though accompanied by the same nimble twists and turns and graceful evolutions in pursuit of insect prey. Settles from time to time near the tips of leafless trees to rest and preen, perching bolt upright with the crest raised. Dips at speed to drink from the surface of forest pools, rising again in a graceful curve.

FOOD. Flying insects — Hemiptera, Coleoptera, etc.

VOICE AND CALLS. A harsh but not unpleasant double note *ti-chuk, ti-chuk* or *whit-tuck, whit-tuck* reminiscent of the scolding notes of the Shikra hawk — uttered chiefly in flight. A trisyllabic *kip-kee-kep*, middle syllable much emphasized, given frequently from a perch (Lowther). Call also described as resembling a parakeet's scream (Nichols).

BREEDING. Season, December to July, varying with 'locality'. Chiefly January to March/April in the Peninsula; March to May and again September in Ceylon. *Nest*, a ridiculously tiny and shallow half-saucer c. 50 × 30 mm across, and 10-12 mm deep in the middle. Made of scales or flakes of papery bark, more or less uniform in size and shape, and small feathers, agglutinated together with the birds' saliva; attached bracketwise to the side of a thin horizontal branch, 20 to 50 mm in diameter, near the top of a leafless tree, 4 to 18 m above the ground. Nest practically invisible from below or merely as a small knot in the branch. *Egg*, a singleton, glossless white with a faint bluish tinge when fresh; elongated oval, obtuse at both ends, filling the diminutive nest completely. Average size of 29 eggs 23.7 × 17.1 mm (Baker). Both birds partake in nest-building, incubation, and feeding the young. Incubation period undetermined. The incubating bird perches upright on the branch against the nest puffing out its breast and abdomen feathers to cover the egg and nest. The nestling, clad in grey down, remains rigid and immobile in the nest with its bill pointing slightly upward, simulating to perfection a lichen-covered snag cf. *Hemipus* (1065) and *Tephrodornis* (1070). Older young in mottled juvenile plumage perches and more or less upright by nest, like incubating adult, with head, neck and bill extended upward and crest raised, thus becoming extraordinarily camouflaged. [For good accounts of the breeding biology see H. Whistler, JBNHS 34: ed.]

58

APODIFORMES

BREEDING. Season, chiefly March to August in the plains; April to June in the hills. *Nest* as in 707 but commonly built under projecting eaves or in the roofs of village houses thatched with grass, bamboo leaves, and palm leaves. Sometimes under large downhanging leaves of palms, e.g. the Tok palm (*Livistona jenkinsiana*) in compounds, frequently within hand reach. *Eggs* 2 or 3; average size of fifty 17.1 × 11.7 mm (Baker).

MUSEUM DIAGNOSIS. Differs from *batesianis* (707) in being darker, with a shorter, less deeply forked tail. *Above*, blackish brown, the wing-quills and tail almost black with a slight gloss. *Below*, dark brown, sometimes slightly paler and greyish on chin and throat.

MEASUREMENTS. Wing ♂ ♀ 113-126 mm (Baker).

COLOURS OF BARE PARTS. As in 707.

Subfamily HEMIPROCNINAE

Differs from swifts of the subfamily Apodinae in the character of the tarsi and feet which superficially resemble swallows'. Hind toe not reversible, and unlike other swifts the birds are capable of perching like a true passerine.

Genus HEMIPROCNE Nitzsch

Hemiprocne [nominative plural] Nitzsch, 1829, Obs. Av. Arter. Carot. Comm.: 15 and note. Type, by subsequent designation, *Cypselus longipennis* Temminck = *Hirundo longipennis* Rafinesque

Sincipital plumes long and erectile forming a frontal crest. Tail long and deeply forked. Wings when folded reach nearly to end of tail. Sexes dimorphic in plumage and young unlike adult. There is a patch of silky down feathers on each flank. Only a single species and race within our limits.

709. Crested Swift. *Hemiprocne longipennis coronata* (Tickell)

Hirundo Coronata Tickell, 1833, Jour. Asiat. Soc. Bengal 2: 580
(Jungles of Borabhum and Dholbhum)

Hemiprocne longipennis dyas Ripley, 1950, Proc. Biol. Soc. Washington 63: 101
(Juna Rajpipla, South Gujarat)
Baker, FBI No. 1616, Vol. 4: 354
Plate 56, fig. 1

LOCAL NAMES. *Dao hadi ko* (Cachari); *Tājdar 'abābel* (Hindi); *Wāhi Kāhīyā* (Sinhala); *Chōtāliyo ābābelo* (Gujarati); *Sārāppākshi* (Malayalam).

SIZE. Bulbul ±; length c. 23 cm (9 in.).

FIELD CHARACTERS. A slender blue-grey swallow-like bird with a prominent backward curving frontal crest, erected when perched.

Male. *Above*, bluish grey glossed with green. *Below*, chin, throat and sides of face: chestnut; breast ashy grey, passing into white on abdomen and under tail-coverts.

Female, similar but lacking the chestnut on the face and throat.

Flight, and appearance on wing, very like palm swift, but larger size, white underparts and more

TROGONIFORMES

60

772-7 (photos); J. K. Stanford and H. C. Smith, *ibid.* 39: 125-6; E. H. N. Lowther, *ibid.* 39: 116-24 (photos).]

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

Young (immature). *Above*, feathers finely edged with pure white with broad subterminal bands of pale brownish grey. Scapulars and innermost secondaries broadly grey-white at the ends, with very fine brown subterminal lines. *Below*, feathers edged with white and sub-edged blackish.

MOULT. Postjuvinal moult apparently does not include primaries and coverts, secondaries and greater coverts, tertiaries and tail. Except for these unmoulted parts, first-year male agrees with adult male. A complete moult in autumn in which the body plumage is usually changed well before the wings and tail. There appears to be a partial body moult in spring (Whistler).

Nothing is known about the patch of silky downy feathers on the flanks or the curious decomposed edges to the tertiaries which in some examples show up as a conspicuous patch.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail central outer
14 ♂♂	141-156	11-12	7-9	40-47 110-135 mm
10 ♀♀	148-160	11-13	7-9	40-46 124-127 mm (HW, SA)

Baker gives for ♂ ♀ Wing 151-165 mm.

COLOURS OF BARE PARTS. Iris brown. Bill horny black; mouth greyish pink. Legs and feet pinkish brown; claws blackish brown.

Order TROGONIFORMES

For morphological details see Stresemann, E., 1927-34, *Acas*: 833; Baker, 1927 FBI 4: 314 (Sub-order Trogones).

Family TROGONIDAE: Trogons

For description see Van Tyme, J., and Berger, A. J., 1959: 469; Eugene Eisenmann, 1964. Article 'Trogon' in Thomson, A. L. (ed.) *New Dict. Birds*, London & New York.

Genus HARPACTES Swainson

Harpactes Swainson, 1833 (1832-33), Zool. Ill. (2), 3: 107 (in key). Diagnosis only, no type or included species. Species added, Swainson, 1837, *Classif. Bds.* 2: 317

Type, by subsequent designation, *Trogon malabaricus* Gould

Bill short, strong and wide; tip of culmen boldly hooked and toothed. Nostril and base of bill well covered with bristles; cheeks partly naked. Feet small, unfeebly, half feathered. Tail long, the rectrices broad and squarely truncated in adult. Pointed in young; of 12 broad feathers, the outer three pairs steeply graduated. Wing rounded, of 10 primaries; inner primaries and secondaries very short. Body plumage soft and dense; skin very thin.

(Foot of Mahendragiri, Orissa)

Baker, FBI No. 1585 (part), Vol. 4: 317

Cf. Salim Ali, 1949, JBNHS 48: 806-8

LOCAL NAME. *Kufni chiri* (Hindi).

SIZE. Myna \pm , with longer tail; overall length c. 31 cm (12 in.).

FIELD CHARACTERS. As of 711, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident. Southern Gujarat (Surat Dangs) and northern Maharashtra (Khandesh) south to c. lat. 20°N., eastward, presumably over the Satpura trend, through Madhya Pradesh (Bastar dist.) to Chota Nagpur and Orissa (Mahendragiri); from plains level to c. 1200 m. Affects moist-deciduous and semi-evergreen forest.

GENERAL HABITS, FOOD, VOICE and CALLS. As in Malabar Trogon (711).

BREEDING. As in 711.

MUSEUM DIAGNOSIS. Differs from *H. f. malabaricus* (711) in being larger and brighter coloured.

Male. Head (and breast) greyish black r. deep sooty black in 711. Upperparts bright yellowish brown, less suffused with chestnut, particularly on upper tail-coverts.

Female. Above, upper back darker with an olive tinge (more or less concolorous with head), contrasting strongly with bright rufous-orange of rump and upper tail-coverts.

Females from S. Gujarat are somewhat intermediate between the Kerala population and that of eastern Madhya Pradesh and Orissa.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail

63

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit. Differs from the nominate race of Ceylon (712) in the male having a much darker sooty black head and breast r. leaden grey-black. No difference in female.

Young (immature) male has crimson of underparts replaced by pinkish salmon or buffy brown (as in female), variegated with red. Primaries, secondaries and some of the lesser coverts are evidently retained from juvenile plumage, as is also the tail. Juvenile rectrices narrower; central pair not squarely truncated but with normal rounded tips, and lacking the black terminal band.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
16 ♂♂	122-129	20-23	13-15	156-180 mm
10 ♀♀	122-131	20-21	13-15	162-167 mm
				(SA, HW)

Weight 2 ♂♂ 62, 64; 2 ♀♀ 60, 64 g (Rensch, SA)

COLOURS OF BARE PARTS. Iris dark brown; orbital and sub-orbital skin bright cobalt blue. Bill blue, black on culmen and tips of both mandibles; mouth pink. Legs and feet pale blue; claws horny brown.

712. *Harpactes fasciatus fasciatus* (Pennant)

Trogon fasciatus Pennant, 1796, Indian Zool.: 4, pl. 5 (Ceylon)

Harpactes fasciatus parvus Deraniyagala, 1954, Admin. Rep. of the Dir. Nat. Museums Ceylon, for 1953. Pt. iv, Educ., Sci., and Art (E): E9 (Thanni arripu, N.P., Ceylon)

Baker, FBI No. 1584, Vol. 4: 316

LOCAL NAMES. *Gini kurullā*, *Nāva nīla kurullā*, *Ramren kōndea* (Sinhala).

SIZE. Myna \pm , with longer tail; overall length c. 31 cm (12 in.).

FIELD CHARACTERS. As of 711, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Race peculiar to Ceylon. Resident. Moderately plentiful in forest areas throughout the Island to over 1800 m; more plentiful in the Wet zone rain-forests than elsewhere (Phillips).

GENERAL HABITS, FOOD, VOICE and CALLS. As in 711. Observed plunging in pool from overhanging branch to bathe (CBCN, July 1972: 37).

BREEDING. *Season*, March to June, chiefly March and April. *Nest* and *eggs* as in Malabar Trogon (711), the latter even more spherical, measuring c. 25 x 24 mm.

MUSEUM DIAGNOSIS. Slightly smaller than *malabaricus* (711) with a shorter tail, actually and comparatively. Head and breast of male paler, a leaden grey-black r. sooty black in the former. No significant colour difference in females of the two. For details of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♀	118-126	20-21	13-15	139-152 mm
				(HW)

COLOURS OF BARE PARTS. As in 711.

62

TROGONIFORMES

FIELD CHARACTERS. A brilliantly coloured bird with a relatively long, broad and curiously square-ended tail.

Male. Head, neck and breast sooty black. Back yellowish brown; wings blackish with fine wavy white barring. Underparts brilliant crimson-pink divided from black breast by a prominent white gorget.

Female duller, with the underparts orange-brown instead of crimson-pink.

STATUS, DISTRIBUTION and HABITAT. Resident. Peninsular India in the Western Ghats complex, south of the range of *legerli* (710), i.e. south of c. 20°N.—through Maharashtra, Goa, Mysore, Tamil Nadu, and Kerala; from plains level to c. 1500 m. Sight records from Andhra — Amrabad Plateau c. 700 m, Nallamalai Hills (SA, JBNHS 37: 136) and Sankrametta c. 1200 m (Vishakhapatnam dist., La Personne, ibid. 38: 28). Affects evergreen and moist-deciduous forest.

GENERAL HABITS. Essentially a forest bird with a preference for secondary moist-deciduous and mixed bamboo jungle. Arboreal, sluggish, and somewhat crepuscular, often hunting till well after sunset. Usually keeps singly or in widely separated pairs perched bolt upright and inert on low branches and tree-stumps for long periods, sallying out occasionally after winged insects. Seemingly possesses an uncanny knack of always keeping the dull coloured back turned to the observer. The broad truncated tail, as broad as the body, then looks like a strip of bark or a dry leaf, camouflaging the bird in an astonishing way. The peculiar mewing calls are usually the first indication of its presence in any patch of jungle. Has a curious habit, when alarmed or apprehensive and preparing to fly off, of bending forward and expanding and flicking up the tail every little while to the accompaniment of a low mewing twitter. In the initial spurt of taking wing, flutters or spins rapidly from side to side like a dove suddenly frightened, the pointed primaries and expanded tail screwing this way and that in the precipitate action. Jerky 'saw-toothed' braking movements before alighting also recall a dove's. Flits from one vantage point in the forest to another, the tail frequently flicked open and shut as it goes, flashing the white lateral feathers. Captures flying insects on the wing, turning and twisting in the chase with the graceful agility of a Paradise Flycatcher. Will sometimes cling laterally to tree-trunks and branches to snatch an insect, or hover momentarily in front of a bunch of leaves to do so; occasionally also swoops to the ground in the quest.

FOOD. Caterpillars, beetles, grasshoppers, cicadas and other insects; also leaves and berries.

VOICE and CALLS. A throaty, rather abrupt musical *mew* or *cue* (of near oriole quality) usually in runs of 3 (*cue-cue-cue*) — sometimes 4 and even 5 — either quickly repeated or unhurriedly and deliberately. A low rolling creak, *krr-r-r-r*, when alarmed or apprehensive.

BREEDING. *Season*, chiefly February to May. *Nest*, an unlined natural hollow in or on top of a broken tree-stump in deep forest, usually under 6 m from the ground. A flimsy stick-nest like a dove's has been reported (JBNHS 39: 24). *Eggs*, 2 to 4, pale ivory white, glossy, unmarked, rather spherical. Average size of 30 eggs 26.7 x 23.4 mm (Baker). Evidently both sexes partake in incubation; period unrecorded.

TROGONIFORMES

HARPACTES ERYTHROCEPHALUS (Gould): REDHEADED TROGON

Key to the Subspecies

	Page
Smaller: Wing 143-148 mm	<i>H. e. erythrocephalus</i> 66
Larger: Wing 142-168 mm	<i>H. e. hodgsonii</i> 64

713, 714. *Harpactes erythrocephalus hodgsonii* (Gould)

Trogon (Harpactes) Hodgsonii Gould, 1838, Monogr. Trogonidae, List of pl. No. 34 (Nepal). Restricted by Biswas to Hitauna, Chisapani Garhi Province, Nepal

Harpactes erythrocephalus helenae Mayr, 1941, Ibis: 495

(Nyetmawhka, 8500 ft, Myitkyina dist., Upper Burma)

Baker, FBI No. 1586 (part), Vol. 4: 318

LOCAL NAMES. *Sūda sohāgin* ♂, *Kūchikūchia* ♀ (Bengal); *Hāmāhā pīyārā* (Hindi); *Sakor* (Lepcha).

SIZE. Myna +, with longer tail; overall length c. 35 cm (13½ in.).

FIELD CHARACTERS. Male. Head, neck and breast deep crimson, sometimes with traces of a white breast band. Back and upperparts chiefly rusty brown. Wing-coverts and tertiaries finely vermiculated black and white. Long, broad, truncated square-ended tail black and white. Underparts brighter and lighter crimson.

Female. Head, neck and breast dull orange-brown; rest as in male including crimson underparts.

In both sexes the white in the outer tail-feathers and whitish wing-patch are conspicuous, particularly in flight.

STATUS, DISTRIBUTION and HABITAT. Resident. The Himalayas from Kumaon through Nepal, Sikkim, Bhutan and Arunachal; terai, duars and up to c. 2400 ft. Also the central Assam hill ranges (Khasi, Garo, etc.), Nagaland and Manipur. The form in the last two needs confirming. Affects dense tropical secondary evergreen and mixed bamboo jungle.

Extralimital. Extends into Upper Burma, northern Shan States and western Yunnan.

GENERAL HABITS. Very similar to Malabar Trogon (711), q.v. Silent, sluggish, and rather crepuscular. Perching upright on snags and tree-stumps along shady jungle paths below the foliage canopy, occasionally making sorties after flying insects and making for a new perch after each capture.

x c. 1

TROGONS

65

Right foot, x c. 1

FOOD. Insects and larvae; green grasshoppers, beetles and stick insects (Phasmidae) commonly found among stomach contents. Also eats leaves and berries. VOICE AND CALLS. Usually very silent. An abrupt mewing *cue* as in 711, of rich oriole quality, uttered deliberately and unhurriedly, usually 5 or 6 times, sometimes up to 10; the series repeated every minute or so. 'A single croak as it flew out to capture an insect or seek another perch' (Betts).

BREEDING. Season, April to July, chiefly May and June. Nest, an unlined natural hollow in a rotten tree-trunk, or a deserted woodpecker hole, c. 1.5 to 5 m up, usually in dense jungle. Eggs, 3 or 4, spherical, buff-coloured, highly glossed. Average size of 80 eggs 28.6 x 24 mm (Baker). Both sexes incubate; period unrecorded.

MUSEUM DIAGNOSIS. Differs from the nominate race (715) of East Pakistan and Lower Burma in being larger and deeper coloured, with a smaller Wing/Bill index¹ (Biswas).

Young (immature). Above, wing-coverts black, broadly edged with buff; inner secondaries black, barred on the outer webs and tipped with buff. Below, from throat to vent buff or buffy white.

Nestling described by Hume, 1881, SF 9: 246.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	142-164	18-22	18-20	176-207 mm
♀♀	144-168	19-22	18-20	180-201 mm

(BB, SA, SDR, Stresemann, Mayr)

Weight ♂♂ 85-110 g; ♀♀ 76 g (SA, SDR).

COLOURS OF BARE PARTS. Iris dull red to crimson; orbital skin purplish blue. Bill: upper mandible lavender- or purplish blue, blackish on ridge of culmen and tip; lower mandible purplish at gape, rest black. Legs and feet brownish flesh or light purple.

TROGONS

67

SIZE. Pigeon ±, with longer tail; overall length c. 38 cm (15 in.).

FIELD CHARACTERS. Appreciably larger than Redheaded Trogon.

Male above, dark vinous red (or maroon-crimson) appearing almost black in shady forest, but crimson-pink graduated lateral tail-feathers conspicuous in flight. Central tail-feathers black, squarely truncated at tip. Below, throat and breast dark vinous red like head; rest of underparts rich crimson-pink.

Female dark olive-brown on head, back, throat and breast. Rest of underparts orange primrose-yellow. Tail as in male but lateral feathers pale primrose-yellow instead of pink.

STATUS, DISTRIBUTION AND HABITAT. Resident at fairly high elevations in the eastern Himalayas, between c. 1500 and 3000 m, from the Mishmi Hills westward through NEFA and Bhutan to at least c. 90°40'E. (Shamgong Dzong). Affects the lower storey and evergreen undergrowth and bamboo in tall subtropical hill forest of *Quercus*, *Castanopsis*, etc.

Extralimital: Upper Burma; North Vietnam.

GENERAL HABITS. Typical of the trogons, see 711. Keeps singly or in separated pairs. Has the same fussy fluttering flight when sallying to capture a winged insect or shifting from one perch to another.

FOOD. Insects — moths, stick insects (Phasmidae), grasshoppers, bugs, etc. — and berries. 'Large seeds, probably acorns' (Stanford).

VOICE AND CALLS. Little known; normally very silent. One call of male described as 'a soft *kew-kew-kew-tiree* at intervals' and another (alarm?) note as *whirr-ur* (Smythies).

BREEDING. No nest recorded as yet, but specimens collected in central Bhutan on 5 and 8 April had fully mature gonads, the distended oviduct of one female indicating that she was laying.

MUSEUM DIAGNOSIS. Supplementing the Field Characters (q.v.) the male has velvety black lores, lateral edge of forehead, and ring around eye. Upper wing-coverts and innermost secondaries black, very finely vermiculated with grey. A large concealed white patch at base of secondaries. Outer webs of primaries 2-6 finely edged with white. In museum skins (in the closed wing) these edges superficially look very like white shafts to the primaries.

Female. Forehead, especially in front of eyes, bright primrose-yellow; wing-coverts and innermost secondaries finely vermiculated golden brown. White edges of primaries 2-6, and patch at base of secondaries, as in male.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
6 ♂♂	167-177	17-19 (2 msd.)	17-18 (2 msd.)	218-233 mm
5 ♀♀	169-175	18-19 (4 msd.)	18 (2 msd.)	210-228 mm

(Mayr, SA, SDR)

Weight 2 ♂♂ 115, 120 g; 2 ♀♀ 120, 120 g (SA).

COLOURS OF BARE PARTS. Iris ♂♂ reddish brown; orbital skin azure blue. Bill ♂ red; ♀ horny brown, pink for c. 1 cm laterally at base of lower mandible. Legs and feet ♂ pinkish flesh colour; claws pale pinkish horny.

Plate 57, fig. 1

LOCAL NAMES. *Suda sohagin* ♂, *Kuchkuchia* ♀ (Bengal).

SIZE. Myna +, with longer tail; overall length c. 35 cm (13½ in.).

FIELD CHARACTERS. As of 713, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident. East Pakistan (Chittagong and Tippera hill tracts), Tripura, Mizo Hills (?); from the foothills to c. 1800 m. Affects evergreen jungle.

Extralimital. Extends into Lower Burma south to Tenasserim, and NW Thailand.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 713. Call described as 'rather plaintive, of 6 to 10 notes on a monotone *tyaw-tyaw, tyaw...* at c. 2 per second' (Smythies, JBNHS 44: 226).

BREEDING. Season, nest, eggs and breeding biology as in 713.

MUSEUM DIAGNOSIS. Slightly smaller and less richly coloured than *hodgei* with a larger Wing/Bill index

LOCAL NAMES. *Mdikhhi taag* (Hindi, Dun); *Jal kutara* (Chamba); *Ung-la-eh* (Lepcha).

SIZE. House Crow ±; length c. 41 cm (16 in.).

KINGFISHERS

69

FIELD CHARACTERS. A large, crested black-and-white kingfisher with cross-barred back.

Male. *Above*, prominent erectile crest black, spotted and streaked with white; wings and tail blackish grey, boldly spotted and barred with white. A broad white half-collar on nape. *Below*, white; a broad pectoral band of black spots mixed with rufous-brown; flanks, sides of abdomen and under tail-coverts barred with blackish.

Female similar, but with under wing-coverts and axillaries pale rusty or cinnamon clearly noticeable in flight.

Young (immature) like female.

STATUS, DISTRIBUTION and HABITAT. Resident. The Himalayas from Kashmir through Himachal Pradesh, Garhwal, Kumaon, Nepal and Sikkim to western Bhutan; from the terai locally to c. 2000 m; sometimes extending into the adjacent plains. Partial to well-wooded spots at the junction of rocky torrential feeder streams with main rivers.

GENERAL HABITS. Not abundant, and rather local and parochial; usually very wary and difficult to approach. Keeps in pairs, perched together or separately on rocks or snags at the edge or amidst a torrent overlooking a swirling pool; only rarely at lakes (e.g. in Kashmir Valley) and tarns. Haunts a favourite beat of river day after day. Perches upright and still; bobs or 'pumps' head from time to time, raising the crest and switching up the tail almost double over the back. Dives obliquely into the water from the fishing post to capture its prey near the surface; does not normally hover and plunge vertically from the air in the spectacular manner of the smaller Pied Kingfisher (719). Flight swift and stately, with deliberate wing-beats, usually low over the rushing water.

FOOD. Fish up to 15 or 18 cm long. Alleged to do much damage to trout in Kashmir streams and is greatly persecuted on that account.

VOICE and CALLS. Normally very silent. Occasionally utters a single sharp click. 'More rarely a loud hoarse grating sound repeated rapidly several times' (Osmaston). 'A loud ping similar to one of the calls of the Redwattled Lapwing' (Whistler).

BREEDING. *Season*, chiefly March and April. *Nest*, a horizontal tunnel dug into a vertical stream-bank sometimes over a metre and a half long, ending in a widened egg-chamber. Unlined but soon becoming strewn with smelly cast-up fish bones. *Eggs*, 4 or 5, white, roundish; average size of 20 eggs 38.5 x 32.5 mm (Baker). *Share of the sexes* in excavating nest-tunnel and incubation, and incubation period, unknown.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit. Differs from the East Himalayan *guttulata* (718) in being paler. Back and upper wing-coverts less blackish, the white spots on the feathers of these areas being larger — more like bars, less like spots. There is also a slight increase in the amount of white on the outer feathers of the crest, making it look less black.

LOCAL NAME. *Das natu meberang gadaba* (Cachari).

SIZE. House Crow ±; length c. 41 cm (16 in.).

FIELD CHARACTERS. As of 717, q.v. In flight along a forest stream in dense shade looks remarkably large and uniformly blue-grey above with prominent white nuchal collar and sharply contrasting black crown. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. The Eastern Himalayas from central Bhutan eastward through NEFA; Assam hills north and south of Brahmaputra river, Nagaland, Manipur and East Pakistan hills; foothills and up to c. 1800 m. Affects rapidly flowing rocky streams and torrents, and the larger rivers in the foothills.

Extralimital. Eastward through China, north to the Tsin-ling Mts. and southern Chihili; south through Burma to Tenasserim; Thailand and North Vietnam.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 717.

BREEDING. *Season, nest, eggs* and breeding biology as in 717.

MUSEUM DIAGNOSIS. Differs from the West Himalayan *continentalis* in being darker, more slaty, with the white spots on the back and upper wing-coverts smaller and less like bars. Forehead and crest darker black with smaller white stippling and streaks.

72

CORACIIFORMES

see 720), Nepal, Sikkim, Bhutan. Both Pakistans (including Baluchistan and NWF district). Ceylon. From sea level to c. 1800 m in Kashmir and the Himalayas and peninsular hills. Affects every kind of stagnant fresh water — sluggish rivers, streams and canals, jheels, irrigation reservoirs, village tanks and flooded ditches — in open country. Occasionally also tidal creeks and intertidal rock pools on the seashore.

Extralimital. Westward through Afghanistan, eastward to Vietnam. Burma south to Tenasserim; Thailand.

GENERAL HABITS. Usually keeps in pairs; sometimes singly and periodically in family parties of 4 or 5. Commonly seen perched together or separately on a rock or stake near water, flicking up its tail and bobbing, or 'pumping', the head every little while. Its most outstanding characteristic is the spectacular mode of hunting. Flies 8 or 10 metres up back and forth over a placid stream or other suitable water, bill pointing downward and intently scanning the depths. The bird checks itself abruptly from time to time and remains poised in mid-air 'standing on its tail' bill pointing straight downwards, facing the wind with rapidly hovering wings, to investigate a promising patch or some movement below. When a fish is sighted within striking depth, the bird turns over and hurls itself headlong with wings closed — a veritable bolt from the blue — momentarily vanishing under the surface. It presently reappears with the quarry firmly gripped between the mandibles, and makes for a nearby perch where the struggling victim is battered into submission and bolted down head foremost. Small prey is swallowed in the air.

FOOD. Mainly fish; supplemented with tadpoles and aquatic insects.

VOICE and CALLS. A sharp, lively chirrup chirrup uttered chiefly on the wing.

BREEDING. *Season*, staggered practically over the entire year (except perhaps the rainiest months) varying locally; chiefly February to April. *Nest*, a horizontal tunnel c. 7 or 8 cm in diameter excavated in vertical earth banks of streams and rivers, often 1.5 metres or more in length, ending in a widened egg-chamber. It is usually unlined, but almost invariably littered with smelly cast-up fish bones. *Eggs*, normally 5 or 6, pure white, roundish ovals with a glossy texture. Average size of 100 eggs 29.9 x 21.4 mm (Baker); of 15 from Kashmir 30.3 x 23.6 (BBO). Both sexes partake in excavating the nest, incubation (?) and feeding the young. Incubation period undetermined. In Kashmir the nest-tunnels are used by the birds for roosting in winter (B. T. Phillips, JBNHS 46: 94).

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	133-142	66-68	10-12	66-70 mm
♀♀	139-141	61-70	10-13	65-75 mm
				(SA, HW, CBT)

COLOURS OF BARE PARTS. Iris brown. Bill brownish black, paler at chin; mouth pink. Legs, feet and claws brownish black.

MISCELLANEOUS. Normal flying speed timed over a 3-mile route 31 miles (49+ km) per hour (C. H. Donald, JBNHS 33: 204).

KINGFISHERS

73

720. *Ceryle rudis travancorensis* Whistler & Kinnear

Baker, FBI No. 1531 (part), Vol. 4: 246

LOCAL NAME. *Pilli ponnān* (Malayalam).

SIZE. Myna +; length c. 31 cm (12 in.).

FIELD CHARACTERS. As of 719, q.v. Distinctly blacker and more contrastingly 'pied'. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident. Extreme SW. Tamil Nadu (Nagercoil dist.) and Kerala north to Kozhikode (c. 11°15'N.). Affects the coastal backwaters and the larger placid streams in the low country, and hills (rare) to at least c. 1400 m (Munnar). Quite common at Periyar Lake (JBNHS 68: 110).

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 719.

BREEDING. Season, principally November to April. Breeding biology as in the Indian subspecies (719).

MUSEUM DIAGNOSIS. Differs from *leucotelurea* (719) in being much darker, giving the general impression of being black above spotted with white rather than white spotted with black. The extent of the white marking, moreover, is much smaller and the spots less pure white, tending to smoky grey. Black spotting on flanks generally more extensive.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
3 ♂♂	133-139	68-69	11	67-71 mm
1 ♀	140	70	—	71 mm (SA, HW)

KINGFISHERS

75

722. *Alcedo atthis pallasi* Reichenbach

Alcedo Pallasi Reichenbach, 1851, Handb. spec. Orn.: 3, pl. cccxvii, figs. 3043-6 (Siberia)
Baker, FBI No. 1535, Vol. 4: 253

LOCAL NAMES. *Chhātā kīkīlā*, *Nīā* or *Nīā māchhrālā* (Hindi); *Kōlā tōnā*, *Chhātā tōnā*, *Tūntū* (Kashmiri); *Narian shid* (Baluchi).

SIZE. Sparrow +; length c. 18 cm (7 in.).

FIELD CHARACTERS. A dapper little blue-and-green kingfisher with brilliant blue back and rump (conspicuous in flight) and deep rust coloured underparts; short stumpy tail and long, straight, pointed black bill. Other points to confirm its identity are: lores and a band through eye black; chin and throat white; cheeks and ear-coverts rusty-red ending in a white patch on side of neck; a broad greenish blue streak from lower mandible to side of neck. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Partly resident, partly migratory, apparently extralimital as well as local. Status not satisfactorily worked out. West Pakistan (Baluchistan, Sind, Chitral, NW. Frontier districts, Punjab), Kashmir (rare straggler in Ladakh), Himachal Pradesh, northern Uttar Pradesh, Rajasthan (Jodhpur), northern Madhya Pradesh, northern Bihar. Breeding so far proved only in Kashmir where it is exceedingly common. Normally from plains level to c. 1850 m; once observed at 3100 m in Lahul, Himachal Pradesh (Whistler, 1925, *Ibis*: 193). Affects streams, canals, rush-fringed tributary channels, ponds, roadside ditches, etc.

Extralimital. Western Siberia and Transcaspiā to Iran, Afghanistan and Turkistan.

MIGRATION. No ringing data. In winter very common in Sind (where the resident form is evidently *bengalensis*), arriving c. mid October departing by end April (Ticehurst, 1923, *Ibis*: 32). Common in Baluchistan (plains and valleys) November to May, and some reported to breed. Winter visitor to central Makran arriving about August, then largely frequenting the coastal mangroves.

GENERAL HABITS. Usually met singly or in pairs perched on some favourite stake or bund on the edge of water. Very tame and confiding, particularly in Kashmir, freely perching on house-boats within arm's length of the inmates, or on an arching reed overhanging water, to keep a lookout for little fishes rising near the surface. While thus occupied, bill pointing downwards, jerkily bobs its head up and down, turning it from side to side and flicking up the stumpy tail to the accompaniment of a subdued click. Suddenly nose-dives with a splash and disappears under, presently to emerge with a small fish held crosswise in the bill. Flies off with the quarry at top speed to another perch some distance away where the struggling victim is battered into submission and swallowed head foremost. Darts swiftly over the water with quick wing-beats from one vantage point to another or when chasing off an intruder from its favourite beat, uttering sharp squeaky notes. Occasionally will also hover 2 or 3 metres above the water in the manner of the Pied Kingfisher and plummet on the quarry from the air.

CORACIIFORMES

Alcedo hercules Laubmann, 1917, Verh. Orn. Ges. Bayern 13: 105. New name for *Alcedo grandis* Blyth, preoccupied
Baker, FBI No. 1542, Vol. 4: 258
Plate 58, fig. 7

LOCAL NAME. *Dao natu dedao* (Cachari).

SIZE. Myna —; length c. 20 cm (8 in.).

FIELD CHARACTERS. Superficially very like Common or Small Blue Kingfisher (722-724) qq.v., but appreciably larger. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Resident. Rare. Sikkim, Bhutan and east through NEFA. Assam (Cachar, Sylhet), Nagaland, Manipur; East Pakistan. Duars and foothills up to c. 1200 m. Affects shady streams in dense evergreen jungle.

Extralimital. Burma (Chin Hills, Prome-Arakan hills). North Vietnam; Hainan I.

GENERAL HABITS. Apparently not very different from its smaller congener on the whole, but little known beyond that it is rare, keeps singly, and haunts deeply shaded fast-flowing forest streams. Perches low down in overhanging bushes rather than on conspicuous vantage points, and is shy and difficult to observe.

FOOD. Fish and aquatic insects.

VOICE AND CALLS. A loud but soft replica of the note of the Small Blue Kingfisher (723) vide Baker.

BREEDING. Season, March to June, principally April and May. Nest, a horizontal tunnel dug into the steep bank of a forest stream or ravine, c. 8 cm in diameter and usually between 45 and 70 cm long, ending in a widened egg-chamber. Most holes are smelly with a considerable amount of insect and fish remains littered in the egg-chamber and along the tunnel. Eggs, 4 to 6, glossy, white, roundish ovals. Average size of 45 eggs 26.1 x 21.7 mm; both sexes incubate (Baker).

MUSEUM DIAGNOSIS. See Key to the Species; for details of plumage Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂♀	95-102	48-55	c. 11	45-47 mm (Baker)

COLOURS OF BARE PARTS. Iris blood red. Bill black, base of lower mandible in ♀ reddish; mouth blood red. Legs and feet coral-red.

CORACIIFORMES

76

FOOD. Small fish, tadpoles and aquatic insects. Once observed carrying a frog about 4 cm long into nest tunnel (Magrath).

VOICE AND CALLS. A shrill piping or trilling *chichee*, *chichee* or *chickichee* as it dashes along above the water.

BREEDING. Season in Kashmir chiefly April and May; once September on circumstantial evidence (Magrath, JBNHS 21: 661). Nest, a horizontal tunnel c. 5 cm in diameter burrowed into the vertical earth bank of a stream or channel, from 25 to 100 cm long, terminating in a widened egg chamber c. 13-16 cm across. An evil stench invariably pervades the nest due to remains of fish and other food littered about. Eggs, 5 to 7, gloss white, rather spherical ovals. Average size of 37 eggs 21.2 x 17.6 mm (Osmaston, Kashmir). Both sexes share in excavating the nest, incubation and feeding the young. Incubation period unrecorded; given as 19-2 days for the European race *ispida* (Witherby).

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.; for description of plumages and structure (also bionomics) of the allied European race *ispida* Witherby, 1938, 2: 275-6. *A. a. pallasi* differs from both *bengalensis* and *taprobana* in being larger, paler on the underparts and less deep vivid blue and green above.

77

c. 1800 m. Also Andaman and Nicobar islands. Affects streams, canals, village ponds, flooded roadside ditches, etc. in open country; also intertidal rock pools on the seashore, and mangroves.

Extralimital. A large part of SE. Asia including Burma, Thailand, the Indochinese countries, Malay Peninsula and islands, and the Philippines.

Right foot, x c. 1

GENERAL HABITS, FOOD, VOICE and CALLS. As in 722.

BREEDING. *Season.* chiefly March to June. *Nest, eggs,* and breeding biology as in 722. Average size of 40 eggs 20.9 × 17.6 mm (Baker).

MUSEUM DIAGNOSIS. Smaller (except the northernmost populations) and brighter coloured than *pallani*; like it usually more green less blue than *taprobana*. Odd non-breeding examples of the last two, especially from intermediate areas, impossible to place with certainty due to individual as well as seasonal variation in amount of blueness and greenness. Except in comparable series, this character not sufficiently reliable for subspecific determination. Situation further obscured by possible intermingling of races under stress of factors such as drought, causing local migration in search of fish food.

MEASUREMENTS			
	Wing	Bill (from skull)	Tarsus
♂♂	68-76	42-46	8-10
♀♀	69-74	43-45	9-10
			30-37 mm (SA, BB, Koelz)

COLOURS OF BARE PARTS. As in 722.

724. *Alcedo althys taprobana* Kleinschmidt

Alcedo ispida var. *taprobana* Kleinschmidt, 1894, Orn. Monatsb. 2: 126 (Ceylon) Baker, FBI No. 1534, Vol. 4: 252

LOCAL NAMES. *Māl pīlīhādunō* (Sinhala); *Meenotti* (Tamil); *Nīlā buchegādu* (Telugu); *Podi ponmān* (Malayalam).

SIZE. Sparrow +; length c. 18 cm (7 in.).
FIELD CHARACTERS. As of 722, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident; common. Peninsular India south of the arbitrarily fixed boundary at 20°N. lat. (around which it intergrades with *bengalensis*), and Ceylon. Plains and hills to c. 1800 m. Affects streams, irrigation channels, ponds, roadside ditches, etc. in open country.

GENERAL HABITS, FOOD, VOICE. As in 722.

BREEDING. *Season,* February to September in S. India, chiefly March-April; November to June in Ceylon. *Nest and eggs* as in 722. Five eggs in S. India and 3 to 5 in Ceylon form the normal clutch. Average size of 48 eggs 20.4 × 17.2 mm (Baker).

MUSEUM DIAGNOSIS. Compared with *bengalensis* (723) this subspecies has the upperparts markedly blue in colour v. green in the former. There is no consistent difference in size, and the variability in the amount of blueness and greenness, unless

KINGFISHERS

79

FOOD. Mainly fish and aquatic insects.
VOICE and CALLS. Like 723 but somewhat sharper.

BREEDING. *Season,* in the northern parts of its range April to August, chiefly May and June; in Kerala c. January. *Nest,* a horizontal tunnel, as in 723, drilled into the bank of a forest stream, up to 1.5 m in length ending in a widened egg-chamber c. 12 cm in diameter. *Eggs,* normally 5 to 7, sometimes 8, glossy white rather spherical, similar to those of *A. a. bengalensis*. Average size of 50 eggs 20.3 × 17.6 mm (Baker). Breeding biology unrecorded.

MUSEUM DIAGNOSIS. Distinguished from *Alcedo a. bengalensis* (723) by its deeper blue upperparts, blue ear-coverts and lack of white neck-patches. For details of plumage see Baker, loc. cit., but as pointed out by Teechurst (JBNS 34: 472), anterior crown tinged with cerulean blue, not greenish.

Young (immature) has the cheeks and ear-coverts rufous, sometimes with a blue line under them. Bill reddish, with whitish tip.

MEASUREMENTS			
	Wing	Bill (from skull)	Tail
♂♀	62-74	43-45	c. 9
			28-30 mm (Baker, SA)

COLOURS OF BARE PARTS. Iris brown. Bill: upper mandible blackish or horny brown, lower brownish orange; gape and mouth orange-coral. Legs, feet and claws orange-coral.

726. *Alcedo meninting phillipsi* Baker

Alcedo meninting phillipsi Baker, 1927, Bull. Brit. Orn. Cl. 47: 72 (Cocoaawatte Estate, Ceylon) Baker, FBI No. 1537, Vol. 4: 255

LOCAL NAMES. Same as for 724; evidently not differentiated from it.
SIZE. Sparrow; length c. 15 cm (6 in.).

FIELD CHARACTERS. As of 725, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident (?); very scarce. Ceylon; possibly also the humid Western Ghats strip of the Indian peninsula (cf. 725). In Ceylon affects 'a few secluded waters in the Dry zone and occasionally ascends streams into the lower foothills to nearly 2000 ft' (c. 600 m) — Phillips.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 725.

BREEDING. Not recorded in Ceylon.

MUSEUM DIAGNOSIS. Distinguished from *coltarti* (725) by deeper royal blue upperparts, with the spots on the wing-coverts large and conspicuous. Ferruginous underparts also darker.

MEASUREMENTS

Alcedo Asiatica Swainson, 1821, Zool. Ill. 1, pl. 50 ('Some part of India' = Bengal) Not *Alcedo asiatica* Menschen, 1787, Mus. Geversianum: 54, no. 262
Alcedo meninting coltarti Baker, 1919, Bull. Brit. Orn. Cl. 39: 39 (Saddya, Assam)
Alcedo laubmanni Mathews, 1925, Bull. Brit. Orn. Cl. 46: 21. New name for *Alcedo asiatica* Swainson, preoccupied
Baker, FBI No. 1540, Vol. 4: 256
Plate 58, fig. 5

LOCAL NAMES. Unrecorded; evidently not differentiated from 723 and 724.
SIZE. Sparrow; length c. 16 cm (6 in.).

FIELD CHARACTERS. A forest representative of the Small Blue Kingfisher (723), very similar to it but slightly smaller and much darker coloured above — deep purplish blue — with blue ear-coverts instead of ferruginous. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Resident. Nepal, Sikkim, Bhutan, NEFA (?), Assam, Nagaland, Manipur, East Pakistan, West Bengal, Orissa. Also the humid Western Ghats strip in Goa, Mysore, Tamil Nadu (Nilgiri Hills) and Kerala, but the subspecific identity of this population needs confirmation; may be closer to *phillipsi* of Ceylon. In general less common than Small Blue Kingfisher; affects small hill-streams in evergreen or heavy bamboo forest to c. 1000 m, occasionally to c. 1500 m. Prefers densely shaded spots.

Extralimital. Burma, Thailand, and the Indochinese countries.

GENERAL HABITS. Very like those of the Small Blue Kingfisher (723) but almost exclusively confined to forest. Keeps singly, perched quietly on low herbage overhanging a shaded rocky streamlet, bobbing its head and jerking up the tail from time to time. Drops vertically on its prey with a splash, often going completely under. Presently reappears with a small fish, and usually flies off with it to a nearby perch.

COLOURS OF BARE PARTS. As in 725.

726a. *Alcedo meninting rufigaster* Walden

Alcedo rufigaster Walden, 1873, Ann. & Mag. Nat. Hist. 12 (4): 487 (South Andaman Island) Baker, FBI No. 1541, Vol. 4: 257

LOCAL NAMES. None recorded.
SIZE. Sparrow; length c. 15 cm (6 in.).

FIELD CHARACTERS. As of 725, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident. South and Middle Andaman Is. More abundant here than *A. a. bengalensis*, keeping to small forest streams and narrow mangrove-fringed tidal creeks 'occasionally venturing out to the fishing stakes at their mouths' (W. Davison).

GENERAL HABITS, FOOD, VOICE and CALLS. As in 725.

BREEDING. *Season,* all nests found by Osmaston between June 25 and July 15, thus apparently a late breeder (JBNS 17: 162); tunnels in banks of forest streams as in 725. *Eggs,* 5, also similar — glossy, white, broad ovals. Average size of 40 eggs 20.3 × 17.6 mm (Baker).

MUSEUM DIAGNOSIS. Differs from the other races in being distinctly paler. Blue of back and rump paler, with less of a purple tint. Bars on the head not only less deep and less purple but with a distinct greenish tinge (Baker, 1918, BBOC 39: 39-40). According to him the easiest race to distinguish, but later workers have found it doubtfully separable from *coltarti*!

MEASUREMENTS		
	Wing	Bill (from skull)
♂♀	63-71	43-47
		27-30 mm (HW, Baker)

COLOURS OF BARE PARTS. As in 725.

Genus *CERYX* Lacépède

Ceryx Lacépède, 1799, Tabl. Ois.: 10. Type, by monotypy, *Alcedo tridactyla* Pallas = *Alcedo erithaca* Linnaeus (species added, Daudin, in Buffon, 1802, Hist. Nat. (ed. Didot) 14: 287)

Bill intermediate in form between *Alcedo* and *Halcyon*, less compressed than in the former, not grooved; culmen straight and slightly flattened. Foot with only 3 toes, the inner or second wanting. Tail very short and rounded. First primary (an.) very long, reaching almost to tip of wing.

KINGFISHERS

85

STATUS, DISTRIBUTION and HABITAT. Resident; locally common. All India east and south of a line from the Gulf of Cambay to Dehra Dun. The lower Himalayas in the terai, bhabar and dun of Uttar Pradesh, Nepal and Sikkim, duars of Bengal and foothills of Bhutan; Assam, Nagaland, Manipur; East Pakistan; Ceylon. Lowland and foothills, occasionally following the streams up to c. 1200 m. Affects large, placid, heavily shaded forest streams; also irrigation channels in well-wooded country, and *Pandanus*-lined coastal backwaters (e.g. in Kerala).

× c.

GENERAL HABITS. Keeps singly or in separated pairs, sitting hidden and motionless for long periods up in a leafy branch of a tree overhanging a forest stream, uttering its loud cackling call; occasionally darting down to seize some prey. Does not normally hover over water and plunge like Pied Kingfisher. Except when coursing down a nullah, much oftener heard than seen. In Bengal and Assam frequently perches on telegraph wires overlooking *bheels* and ditches.

FOOD. Fish, frogs, lizards, mice and young birds — sometimes marauded out of tree-holes. Also crabs, water beetles and other manageable animals.

VOICE and CALLS. Very noisy. Has a loud raucous shrieking 'laugh' *Ké-ke-ke-ke*, etc. with explosive accent on the initial *ké*; this uttered with a bobbing up and down of the head and flicking of the tail till it almost touches the back. Also a pleasant contented-sounding song or soliloquy *peer, peer*, *pūr* frequently repeated, delivered from a shady perch.

BREEDING. *Season*, overall January to August/September varying locally and also much staggered; chiefly April and May in the northern parts and Assam, February–March in Kerala, January to May and again August–September in Ceylon. *Nest*, the usual unlined chamber at the end of a horizontal tunnel drilled into the steep earth bank of a stream; up to a metre or more in length and c. 10 cm in diameter. An unusual nest c. 5 m up in a rotten tree stem has been recorded. *Eggs*, 4 or 5, white, glossy, rounded ovals as typical of the kingfishers. Average size of 30 eggs 36.6 × 31.2 mm (Baker). Presumably both sexes share in excavating the tunnel, incubation, and feeding the young, but this not specifically recorded. Period of incubation unknown. Curious behaviour has been observed in the breeding season of a pair charging full tilt repeatedly from a perch some distance opposite into a crack in a brick wall with the point of the bill, accompanied by the loud raucous calls. This 5 or 6 hours each day for several weeks, ultimately achieving a number of small purposeless cavities c. 8 to 10 cm across and 10 to 12 cm deep! (For particulars see K. K. Neelakantan, JBNHS 49: 553–4.)

KINGFISHERS

87

FIELD CHARACTERS. As of 730, q.v. See Key to the Subspecies and Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident; fairly common. Nicobar Islands, but its occurrence on Car Nicobar or anywhere besides Little and Great Nicobar not yet authenticated. Affects swampy mangrove-forest, tidal creeks and the seashore.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 730.

BREEDING. No data.

MUSEUM DIAGNOSIS. Differs from *capensis* (730) in having the crown ochraceous like the nuchal collar, presenting no contrast with it.

MEASUREMENTS

732. *Pelargopsis capensis intermedia* Hume

Pelargopsis intermedia Hume, 1874, Stray Feathers 2: 166: Southern Nicobars; restricted to Galatea Bay, Great Nicobar Island, by Oberholser, 1909, Proc. U.S. Nat. Mus. 35: 666

Baker, FBI No. 1547, Vol. 4: 264

LOCAL NAMES. None recorded.

SIZE. Pigeon ±; overall length, including large bill, c. 38 cm (15 in.).

88

CORACIIFORMES

neck, mantle light rufous-chestnut or cinnamon, overlaid with a red-violet or opal bloom. Middle of lower back, and rump, white tinged with pale blue or violet. *Below*, rufous, varying in depth, paler on chin and throat. Bill and feet bright red. Sexes alike.

Young (immature). *Above*, darker browner chestnut than in adult and lacking the violet bloom; rump and upper tail-coverts deeper blue. *Below*, chin albescent; rest of underparts darker rufous, the feathers from throat to abdomen edged with black. Bill largely black with an orange-red tip; feet dull dirty reddish.

STATUS, DISTRIBUTION and HABITAT. Resident; perhaps commoner than is apparent. The sub-Himalayan terai and duars from Nepal through Sikkim and Bhutan; Assam north and south of Brahmaputra river, Nagaland and Manipur; W. Bengal and East Pakistan (Sunderbans and hill tracts). Apparently subject to sporadic (or regular?) wide-ranging movements. A specimen has been obtained in Tamil Nadu (Chingleput dist.) in November, and the species is regularly taken at lights on certain mountain ridges and passes (e.g. Jātinga, N. Cachar) on dark monsoon nights suggesting definite migration passage; but these movements as yet enigmatical. (For particulars see Sālim Ali, JBNHS 59: 129–30.) Similar nocturnal falls also recorded in lighted bungalows, and regularly at lighthouses and lightships in the Straits of Malacca in the autumn months, October to December (Robinson & Chasen, 1927, 1: 102). Affects mangrove swamps and the neighbourhood of heavily wooded rivulets and pools in evergreen jungle, up to c. 1800 m.

Extratropical. Extends south through Burma and Malay Peninsula to northern Johore; southeastern China, Thailand, the Indochinese countries, and NE. Sumatra.

GENERAL HABITS. Shy and retiring. Keeps singly or in pairs to dense secondary evergreen tangles and cane brakes, occasionally dashing past as a cinnamon flash through the jungle. Oftener heard than seen, and its habits little known specifically.

FOOD. Fish, crabs, beetles, grasshoppers and other insects; doubtless also other animal items.

VOICE and CALLS. Of the same pattern as the Whitebreasted Kingfisher's (735–8) but louder, more musical, and less tinny.

BREEDING. *Season*, mainly March–April. *Nest*, the usual kingfisher tunnel bored horizontally into an overgrown ravine bank in evergreen jungle; c. 45 to 100 cm long and c. 5 cm in diameter, ending in a comparatively small egg-chamber. Sometimes also nests in holes in tree-trunks quite high up. *Eggs*, normally 5 occasionally 6, white glossy, rounded ovals. Average size of 30 eggs 27.3 × 23.2 mm. Both sexes incubate (Baker). Incubation period and other facets of breeding biology unknown.

MUSEUM DIAGNOSIS. For further details of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	106–121	60–63	18–19	60–71 mm (Baker, BB, SA)

COLOURS OF BARE PARTS. Iris dark brown. Bill red, darker at base, pinker and paler at tip. Legs and feet pinkish red to coral-red.

734. *Halcyon coromanda mizorhina* (Oberholser)

Entomothera coromanda mizorhina Oberholser, 1915, Proc. U.S. Nat. Mus. 48: 645 (North Andaman Island)
Baker, FBI No. 1556, Vol. 4: 274

LOCAL NAMES. None recorded.

SIZE. Myna +; length c. 26 cm (10½ in.).

FIELD CHARACTERS. As of 733, q.v. See Museum Diagnosis.

In gloomy tidal forest 'the colour of the bird resembles that of the dry leaf of the mangrove *Rhizophora mucronata*' (Abdulali).

STATUS, DISTRIBUTION and HABITAT. Resident, Andaman Islands. Not uncommon on North Andaman, but scarce elsewhere. Also observed on Barren and Southern Jolly Boy islands (Hume, 1874, SF 2: 169-70). Not recorded in the Nicobars. Affects dense mangrove swamps.

GENERAL HABITS, FOOD, VOICE and CALLS. Nothing specifically described; presumably as in 733.

BREEDING. No data.

MUSEUM DIAGNOSIS. Differs from the Indian *coromanda* (733) in being much darker rufous above, entirely overlaid by a brilliant purple-violet sheen. Below also much darker, with a variable amount of violet bloom on foreneck and breast.

MEASUREMENTS

Alcedo smyrnensis Linnaeus, 1758, Syst. Nat., ed. 10, 1: 116 (Africa and Asia = *Smyrna*, ex Albin)
Baker, FBI No. 1550, Vol. 4: 268

LOCAL NAMES. *Kilkila*, *Kourilla* (Hindi); *Nela mächhrála* (Himachal Pradesh); *Dalāl* (Sind); *Kālkāliya* (Gujarati); *Aspi chidok* or *Aspanchidok* (Baluchi = 'he who chatters at horses').

variable seasonally and in different lights as well as individually, sometimes appearing quite green at other times bright blue.

STATUS, DISTRIBUTION and HABITAT. Resident; common; subject to local movements, some nocturnal and suggestive of regular migration. Frequently taken at lights at certain periods during the monsoon in places where absent at other seasons (cf. Ruddy Kingfisher, 733). Perhaps our most widely distributed kingfisher. All India east and south of the range of 735, from the sub-Himalayan tracts (including those of Nepal and Sikkim) south throughout the Peninsula, and Ceylon. Intergrades with the eastern *perpulchra* (737) in eastern Madhya Pradesh and northern Andhra, but boundaries of the races equivocal. Penetrates considerable distances into the Himalayas locally up to c. 2300 m; also to about the same altitude in the peninsular and Ceylon hills. Less dependent on water than other kingfishers, and found in a very wide range of habitats, often very far away from it in dry deciduous forest. Affects wet paddyfields, flooded borrow-pits and roadside ditches, village tanks, *kutchas* wells, canals, streams, and the sandy seashore. Gardens in towns and fish-curing yards are favourite haunts.

GENERAL HABITS. Keeps singly or in separated pairs, perched upright on a fence-post, telegraph wire or branch surveying its surroundings for crawling prey, often well away from water. While thus perched, swings the downhanging tail back and forth accompanied by a jerky bobbing or pumping up and down of the head from time to time. Normally stoops to the ground like a shrike to seize its quarry in the bill, flying up with it to another perch nearby where, if too large or lively, it is purposefully battered to pulp before being bolted down. Each bird usually has a staked-out feeding territory which is actively defended against interlopers. On approach of the breeding season the male sings obstreperously for considerable periods, chiefly in the early morning, from a favourite exposed tree-top, usually within earshot of other males similarly performing. The singing bird sits bolt upright with the tail turned in under the perch, stiffly flicking open his wings from time to time for a second or two, deliberately flaunting the conspicuous white wing-patches; this even when no other bird is present nearby. Pair-formation behaviour and courtship display not properly studied, but the distinctive wing pattern evidently plays an important part in the proceedings. 'When inviting copulation, the female uttered a prolonged *kil-kil-kil* etc. (like the agitated chattering of Redvented Bulbul) accompanied by a shivering of the partly open wings (as in food-begging) before the male perched a few centimetres away' (SA).

FOOD, small animals; fish only a secondary item. Largely insects — grasshoppers, crickets, mantises, scarab and other beetles including the aquatic Dysticidae; ants and winged termites emerging from the ground. Has been observed capturing locusts and dragonflies on the wing (Whitehead, JBNHS 20: 957). Crabs — *Oxygode* on the sandy seashore, *Paratelphusa* in flooded paddyfields inland; scorpions and centipedes; frogs and lizards (*Mabuia*, *Calotes*, etc.), mice and birds — fledgling sparrows, adult white-eye and munias, and once a downy Redwattled Lapwing chick recorded. Predominantly a terrestrial feeder but individuals occasionally become a nuisance at fish hatcheries and ornamental goldfish ponds.

Bill from above, x c. 4 (After Hartert)

SIZE. Myna +; length c. 28 cm (c. 11 in.).

FIELD CHARACTERS. As of 736, q.v. See Key to the Subspecies and Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident; common and widespread. West Pakistan (Baluchistan, Sind, Punjab) and NW. India (Kashmir, Rajasthan, N. Gujarat with Kutch and Saurashtra) roughly west of a line from the Gulf of Cambay to Dehra Dun; intergrades with *fusca* (736) around the eastern parts of its range. Habitat as in the Indian subspecies.

Extralimital. Extends westward through Iran and Iraq to Asia Minor, south to Arabia.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 736.

BREEDING. Season, in W. Pakistan, Kashmir and NW. Gujarat, overall March to July, varying with local conditions. Nest and eggs (c/5 or 6) as in the Indian race (736). Average size of 30 eggs 29.4 × 26.2 mm (Baker).

MUSEUM DIAGNOSIS. For description of plumage see Baker, loc. cit. Differs from *fusca* in having the scapulars, mantle and tail greener, not so blue; rump usually paler blue; head and underparts often, but not always, paler. There is, however, no constant difference in colour between the two races, and the slightly larger size of northwestern birds as compared with Ceylonese and southern peninsular examples is clinal and in keeping with Bergmann's Rule.

MEASUREMENTS

SIZE. Myna +; length c. 28 cm (c. 11 in.).

FIELD CHARACTERS. A brilliant turquoise-blue kingfisher with deep chocolate-brown head, neck and underparts. Chin, throat, and centre of breast glistening white forming a conspicuous 'shirt-front'. A large white wing-patch, prominent in flight, and long, heavy, pointed coral-red bill and red legs are further clues to its identity. Sexes alike. Upperparts highly

VOICE and CALLS. Normal call well described as 'a loud defiant rattling [or cackling] laugh' (Nichols), uttered chiefly when taking wing. Song, a long-drawn tremulous musical whistle *Kiltili* repeated again and again from a tree-top for long periods, each phrase ending in a detached harsh undertone like the *pench* of a snipe, audible only at close range.

BREEDING. Season, overall January to August, varying locally; mainly April to July, somewhat earlier in Ceylon and S. India. Nest, a tunnel bored in the steep bank of a (usually) dry nullah or roadside cutting, or in the side of a dry ditch, *kutchas* well or borrow-pit; usually sloping slightly upwards, c. 7 cm in diameter and from c. 50 cm to a metre or more long. It ends in a widened egg-chamber, unlined but usually becoming littered with bones and foul-smelling cast-up remains of prey brought for the young. Fresh, occupied tunnels recognizable by the double tracks of loose earth left by the birds' feet as they shuffle in and out. Digging of tunnel in a vertical bank initiated by both birds tilting with the bill into the earth in full flight, one after the other in quick succession until a circular indentation is made to afford foothold for the bird to cling, supported by open wings pressed against the wall, and continue the digging (cf. *Pelargopsis capensis*, 730). Eggs, 4 to 7, normally 5 or 6, pure white spherical ovals, c. 29 × 26 mm. Both sexes share in excavating the nest-tunnel, incubation, and feeding the young. Incubation period undetermined.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit. The Indian *fusca* differs from nominate *smyrnensis* (735) in being usually more blue less green on the upperparts, but this variable seasonally and individually; centre of back generally a deeper blue; chocolate-brown parts slightly deeper in shade.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	113-124	56-63	15-16	72-83 mm (SA, HW, BB)

Weight 3 ♂♂ 78-83 g (GD, SDR); 1 ♂ 79 g (SA).

COLOURS OF BARE PARTS. Adult. Iris brown. Bill brownish orange-red to deep coral-red; mouth orange-brick colour or coral-red. Legs and feet dusky orange to coral-red (brighter on hind tarsus and sole); claws blackish brown. Nestlings. Bill dull yellow and blackish.

LOCAL NAMES. *Sandabuk mächhrānga* (Bengal); *Lāli mächh sorāi* (Assam); *Dan natu gophu* (Cachari).

SIZE. Myna +; length c. 28 cm (c. 11 in.).

FIELD CHARACTERS. As of 736, q.v. See Key to the Subspecies and Museum Diagnosis.

KINGFISHERS

93

STATUS, DISTRIBUTION and HABITAT. Resident; common; subject to local movements. From eastern Madhya Pradesh and northern Andhra [where it intergrades with *fusca* (736)], Orissa and eastern Bihar, eastward through W. Bengal, Bhutan foothills, Assam, Nagaland, Manipur and East Pakistan. *Extralimital.* Burma, Thailand, Malay Peninsula, Indochinese countries, S. and E. China; Hainan and Formosa.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 736.

BREEDING. Season, in Assam chiefly March to June. *Nest and eggs* as in 736.

MUSEUM DIAGNOSIS. Underparts slightly paler than in *fusca* but subspecies doubtfully distinct from it, and separable chiefly with 'the eye of faith'!

MEASUREMENTS, within the range of *fusca* but somewhat on the smaller side.

COLOURS OF BARE PARTS. As in 736.

738. *Halcyon smyrnensis saturation* Hume

Halcyon saturation Hume, 1874, *Stray Feathers* 2: 168, in text: 531 (Andaman Islands) Baker, FBI No. 1553, Vol. 4: 270

LOCAL NAMES. None recorded.

SIZE. Myna +; length c. 28 cm (11 in.).

FIELD CHARACTERS. As of 736, q.v. See Key to the Subspecies and Museum Diagnosis.

'In flight the white wing-patches more conspicuous than in Indian birds' (Abdulali, JBNHS 61: 542).

STATUS, DISTRIBUTION and HABITAT. Resident. Very common and abundant in the Andaman Islands, especially on South and Middle Andamans. Not recorded in the Nicobars. Affects sea coast, mangrove swamps, and forest clearings, frequently far into the interior.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 736.

BREEDING. Season, mainly April and May. *Nest and eggs* (normally 3, sometimes 4) as in the Indian bird. Average size of 60 eggs 30.2 × 26.4 mm (Baker).

MUSEUM DIAGNOSIS. Chocolate-brown of head, neck and underparts distinctly darker than in 736.

MEASUREMENTS

	Wing	Bill (from skull)	Tail
1 ♂	133	72	86 mm
2 ♀♀	128, 129	64, 70	82, 83 mm (Grubb)

♂♀ Wing 123-134; bill (from feathers) 54-63 mm (Baker).

COLOURS OF BARE PARTS. As in 736.

KINGFISHERS

95

seacoast though not an exclusively salt-water species like the Brownwinged Storkbill (729). Dives obliquely from a perch for fish or stoops to the ground like a shrike to take crawling prey.

FOOD. Chiefly fish, frogs and crabs, but also insects—crickets, grasshoppers, beetles, etc.—and presumably lizards and other small animals.

VOICE and CALLS. A cackling laugh like the Whitebreasted Kingfisher's, but shriller and quite distinctive. Song undescribed.

BREEDING. Very few nests taken within Indian limits—in Lakhimpur dist. of Assam, Kerala (*Nidif* 3: 423) and Mysore (Shamoon Abdulali, JBNHS 45: 607), the last containing 2 hatchlings and 2 eggs on 5 May. *Nest*, the usual horizontal kingfisher tunnel, a metre or so deep, drilled into the bank of a stream in wooded country. *Extralimital* season given as May to July, and normal clutch as 4 or 5 eggs—white, spherical ovals. Average size of 46 eggs 29.6 × 26.3 mm (Baker).

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂♀	127-133	57-65	c. 15	83-88 mm (Baker)

COLOURS OF BARE PARTS. Iris dark brown. Bill deep coral-red. Legs and feet dark red.

Halcyon ridali Sharpe, 1892, *Cat. Bds. Brit. Mus.* 17: 217 (in key): 278 (Ratnagiri and Keshi Creek, South Konkan, India) Baker, FBI No. 1558, Vol. 4: 276 Plate 58, fig. 10

LOCAL NAME. *Kāyāl pōmān* (Malayalam).

SIZE. Myna ±; length c. 24 cm (9½ in.).

FIELD CHARACTERS. As for 741, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident; rare and little known. Authenticated only from a small area on the west coast in Ratnagiri dist. (Maharashtra) c. 120 km south of Bombay whence the subspecies originally described. Reported occurrence in coastal Kerala quite probable but not yet confirmed by specimens. Frequents thick mangrove swamps fringing the estuaries of the tidal creeks.

739. Blackcapped Kingfisher. *Halcyon pileata* (Boddaert)

Alcedo pileata Boddaert, 1783, *Table Pl. enlum.*: 41 (China, ex Daubenton, Pl. enlum., no. 673)

Baker, FBI No. 1554, Vol. 4: 271

Plate 58, fig. 8

LOCAL NAMES. *Abāk tānki* (Mirshikars, Bihar); *Kourilla* (Hindi; generally for all kingfishers).

SIZE. Myna +; length c. 30 cm (12 in.).

FIELD CHARACTERS. A medium-sized kingfisher with bright coral-red bill and a large whitish wing-patch (as in Whitebreasted), conspicuous in flight. Readily identified also by its pale rusty underparts including underside of wings. Upper plumage looks black until sunshine transforms it to brilliant purple-blue.

× c. ½

Adult. *Above*, crown velvety black, separated from dark mantle by a prominent white collar on hindneck. Upperparts deep cobalt blue. *Below*, pale rusty buff. Sexes alike.

Young (immature) has numerous black striations running from lower mandible to neck; feathers across breast edged with black.

STATUS, DISTRIBUTION and HABITAT. Resident and locally migratory. Primarily a maritime kingfisher, not common but frequent on the western seaboard from about Bombay southward, Ceylon (rare), and up the eastern coast of the Peninsula through the Godavari delta, Sunderbans and East Pakistan (Chittagong, common), and beyond. Also the Andaman and Nicobar Islands. Affects the seashore and mangrove swamps, often ascending the creeks and estuaries for considerable distances above tidal limits. Sporadically penetrates much deeper inland along the larger rivers and their feeders (up to c. 1000 m); as such, collected and/or observed in Gonda dist. (Uttar Pradesh), Monghyr, Madhubani, Tirhut (Bihar), Dumagudim (Andhra), Bharatpur (Rajasthan), N. Lakhimpur (Assam), Naga Hills north of Manipur (SF 11: 45), and elsewhere.

Extralimital. Extends through Burma, Thailand, Malay Peninsula and islands, the Indochinese countries, China (north to Kansu, Shansi and Chihili), Korea, Hainan, Philippine and Indonesian islands (Borneo, Sumatra, etc.).

GENERAL HABITS. Similar to the Whitebreasted Kingfisher (736) but much less terrestrial in its hunting and less noisy, usually flying off silently. Keeps singly and has a number of alternative fixed hunting posts in a feeding territory, occupying them day after day. Seldom wanders far from the

CORACIIFORMES

96

GENERAL HABITS, FOOD, VOICE and CALLS. As in 741. Feeds at low tide on the exposed mudflats, on crabs, mud-skippers (*Periophthalmus*) and orthopterous insects.

BREEDING. Not recorded.

MUSEUM DIAGNOSIS. Differs from *humii* (741) in being generally brighter and paler blue on the wings and more consistently green on the back; ear-coverts green with no trace of black; black nuchal band generally absent; white collar broader.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂♀	110-116	42-49	c. 16	70-73 mm (Baker)

COLOURS OF BARE PARTS. As in 741.

741. *Halcyon chloris humii* Sharpe

Halcyon humii Sharpe, 1892, *Cat. Bds. Brit. Mus.* 17: 217 (in key): 281, pl. 8 (Siam to the Malay Peninsula and Sumatra; type from Jaam, Selangor, Malay Peninsula, *vide* Oberholser, 1919, *Proc. U.S. Nat. Mus.* 55: 373) Baker, FBI No. 1557 (part), Vol. 4: 275

LOCAL NAMES. None recorded.

SIZE. Myna ±; length c. 24 cm (9½ in.).

FIELD CHARACTERS. A medium-sized maritime kingfisher with a black bill.

Adult. *Above*, crown and upperparts greenish blue; a prominent white nuchal collar running into the pure white underparts. A black band (generally present) from eye to eye encircling the crown behind; a short white supercilium and a white patch under the eye. *Below*, from throat to vent white. Sexes alike.

Young (immature) has the breast feathers edged with dusky producing a barred effect; white collar and underparts sometimes tinged with fulvous, more prominently on flanks and vent.

STATUS, DISTRIBUTION and HABITAT. Resident; common. The Sunderbans and coastal areas of West Bengal, Orissa and Bangladesh. Affects mangrove swamps; also *char* lands in the neighbourhood of villages in 24-Parganas.

Extralimital. Coasts of Burma, Malay Peninsula, Tioman Archipelago; NE. Sumatra.

GENERAL HABITS. Generally similar to Whitebreasted Kingfisher (736); like it also often found far from water since not entirely dependent on aquatic food. A bold and noisy species frequently hanging round fishermen dragging their nets for the fleeing or rejected sprats. 'The flight is curiously hesitant and weak; they look more like a cuckoo-shrike than a kingfisher in flight' (J. K. Stanford).

× c. ½

KINGFISHERS

97

FOOD. Fiddler and other crabs, mudskippers (*Periophthalmus*) taken on tidal mudflats at ebb; grasshoppers, crickets and other orthopterous insects; lizards, centipedes. Once observed flying up to mud nest of termites 6 metres up in tree and pecking at it (feeding?) while hovering momentarily (SA).

VOICE and CALLS. Particularly vocal in the morning. Harsh, unmusical cries of the timbre of the Black Bulbul's (*Hypsipetes*), described as *krerk-krerk-krerk*, in the breeding season. Excessively noisy during courtship, the birds of a pair chasing each other from tree to tree with 'loud raucous laughter'.

BREEDING. Season, March to August, chiefly April and May. *Nest*, a hole up in a tree-trunk or one excavated in a carton or mud nest of tree ants, often a live one; sometimes in a termite mound. Frequently in kampongs and orchards adjoining villagers' huts. *Eggs* 3 or 4, white, roundish ovals. Average size $c. 29 \times 24$ mm. Evidently both sexes dig the nest-hole, incubate, and feed the young. Incubation period undetermined.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit. This subspecies (*humii*) has the upperparts very blue, in some examples practically without any green tinge; ear-coverts all blue; black nuchal band usually absent.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	96-107	40-47	c. 15	62-65 mm (Baker)

COLOURS OF BARE PARTS. Iris deep brown. Bill: upper mandible and terminal third of lower black or deep greenish black; basal two-thirds of lower mandible pinkish or yellowish white. Legs and feet slaty black or plumbeous.

Halcyon davisoni Sharpe, 1892, Cat. Bds. Brit. Mus. 17: 217 (in key): 282 (Aberdeen, South Andaman)
Baker, FBI No. 1560, Vol. 4: 278

LOCAL NAMES. None recorded.

SIZE. Myna \pm ; length $c. 24$ cm (9½ in.).

FIELD CHARACTERS. As for 741, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident; common. Andaman and Coco islands. Recorded on Great and Little Cocos, Little Button, Strait Is., Stewart Sound, Port Cornwallis and elsewhere in the groups. Affects the sea coast, mangrove swamps, tidal creeks, and some distance inland, there keeping to gardens and edges of forest.

GENERAL HABITS, VOICE and CALLS. As in 741.

FOOD. Mainly crabs, fish, grasshoppers and other insects.

BREEDING. Season, principally April-May. *Nest*, a hole excavated in an earth-bank, 30 cm or so deep; occasionally in a termite mound or in the upturned roots of a fallen tree, or a hollow in a tree-trunk (Osmaston, JBNHS 17: 163). *Eggs*, 3 or 4 as in 741. Average size of 30 eggs 29.3×24.5 mm (Baker).

CORACIIFORMES

bhabar, and dun) from about Dehra Dun eastward through Kumaon, Nepal, Sikkim, W. Bengal and Bhutan, Assam, Nagaland, Manipur, East Pakistan, Orissa. Also the Western Ghats complex from about Goa southward (including western Mysore, western Tamil Nadu, and Kerala), and Ceylon; normally up to $c. 1500$ m. Less frequent, or locally absent, in the central, eastern and southeastern parts of the Peninsula, but likely to turn up on passage in almost any forested area. Affects the neighbourhood of streams in mixed deciduous forest country.

Extralimital. Burma, Malay Peninsula, Yunnan, Thailand, the Indo-chinese countries.

GENERAL HABITS. Keeps in parties of 8 to 30 birds or so, perching on bare branches near the top of forest trees or on telegraph wires where available, one bird or several together launching out in the air from time to time to hawk insects, circling back to the base. Flight fast—a few rapid wing-beats followed by a graceful glide. In common with many other insectivorous birds, and other bee-eaters, drinks and bathes on the wing, splashing on the surface while flying low over water or dipping down to it from an overhanging perch, thereafter settling nearby to shuffle the feathers and preen. Has communal roosts in favourite trees in open forest where the birds converge at sundown. Much noise and flying around in a rabble takes place, and settling and resettling as individuals try to supplant others from coveted position in the huddle along a leafy branch. Observed actually taking small fish by dropping from overhanging perch (P. L. Samy, in *epist.*).

FOOD. Winged insects—bees, dragonflies, ants, termites, etc. Occasionally butterflies snapped up in the air with a little click of the bill, the discarded wings floating to the ground as the bird flies on after the capture.

VOICE and CALLS. Almost indistinguishable from those of the large green bee-eaters (747, 748), qq.v.

BREEDING. Season, overall February to June, most generally March and April. *Nest*, a horizontal tunnel drilled into the shelving sandy bank of a stream or in sandy level ground at a gently downward-sloping angle; up to $c. 2$ metres long ending in a widened egg-chamber. Though not colonial, e.g. like Sand Martins, often several nests scattered in a restricted area like rat-holes, a metre or two from one another. *Eggs*, 5 or 6, pure white, roundish ovals. Average size of 200 eggs 21.7×19.0 mm (Baker). Both sexes share in digging the tunnel, incubation, and feeding the young. Incubation period undetermined.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit. Post-nuptial moult complete; apparently no spring moult. Freshly moulted birds have the back dark green (v. pale blue) and the crown and nape rich chestnut-brown. Although the central feathers hardly project beyond the tail, they are quite different in shape from the lateral rectrices, approximating to the condition that obtains in juveniles of Bluetailed and Small Green Bee-eaters (748, 750).

(including islands in the Mediterranean Sea) Morocco, Tunisia, Palestine. Winters in Africa as far south as Cape Province; also in S. Arabia. Occurs on the eastern Atlantic islands during migration; casual in C. and N. Europe (Peters).

Merops apiaster

■ Breeding range

MIGRATION. No ringing data. Recorded as passing through Kohat (33°37'N., 71°30'E.), northern West Pakistan, in April and early May, re-passing in August-September (Whitehead, 1909, *Ibis*: 250). Arrives in Chitral end May, most birds passing on northward (Perreau, JBNHS 19: 917); in coastal Makran early April, in N. Baluchistan throughout April, re-passing southward in August (Ticehurst, JBNHS 31: 878).
GENERAL HABITS. In Kashmir (summer, breeding) keeps in pairs or small communities. Perches on telegraph wires or bushes in exposed situations, darting out now and again to seize a dragonfly or wasp often from as much as twenty metres away, swooping upwards at the end to snap up the quarry with a little click of the mandibles, the bird circling round with the capture back to its perch. Here the victim is vigorously battered to pulp before being swallowed or carried to the nest. Flight graceful, undulating, a few rapid wing-beats alternated with fast glides — very swift when in pursuit.
FOOD. Dragonflies (Odonata), bees, hornets, and other Hymenoptera including the fierce yellow wasp *Polistes hebraeus*; occasionally butterflies (Lepidoptera), all taken on the wing. Sometimes becomes a serious nuisance to bee-keepers by preying on their hive bees.
VOICE AND CALLS. A pleasant, rather liquid trill *tre, tre*, etc., uttered on the wing and from a perch.

102

FIELD CHARACTERS. A typical bee-eater, multicoloured, with long, slender, curving pointed black bill and projecting pin-feathers in tail.

Tail of *M. apiaster*, × c. ½ (After Hartert) Tail of *M. s. persicus*, × c. ½

Adult. Above, mantle chestnut and yellow; tail blue-green, the narrow tips black. Below, checks and throat bright clear yellow separated from blue-green breast and abdomen by a narrow black gorget. Sexes alike.
Young (immature) has very little chestnut on head or neck; scapulars pale green- or blue-grey, the tips almost white; chestnut of wings replaced by chestnut-grey; underparts paler and duller.
STATUS, DISTRIBUTION AND HABITAT. Breeding visitor to Kashmir, chiefly in the Vale, arriving in April or early May, departing in September. Breeds also in Baluchistan (Quetta area) to c. 1800 m, and in the Kurram Valley between c. 900 and 2100 m. Elsewhere in NW. India and Pakistan mainly a passage migrant, recorded in Gilgit, Chitral, Himachal Pradesh, Garhwal, Punjab, Sind, and eastern Rajasthan. Once in Tamil Nadu (Salem dist.), specimens, February 1952 (Basu Roy, JBNHS 65: 776), once in the Maldives Is. — a party of three birds staying on between January and March 1959; status unknown (W. W. A. Phillips, JBNHS 60: 580). Affects open country, low foothills and cultivation, and environs of lakes.
EXTRALIMITAL. Breeds from the Iberian Peninsula, S. France, N. Italy, Yugoslavia, Romania, S. Russia, the Aral Sea and W. Siberia, south to

104

CORACIIFORMES

BREEDING. Season, principally June and July. Nests singly or in communities of a few pairs, widely spaced. Nest, a horizontal tunnel c. 6-9 cm in diameter and up to 2 m deep, ending in a widened egg-chamber c. 23 cm across; usually littered with remains of beetles and winged insects. Excavated in steep banks or cliffs of soft alluvial clay at a slightly upward angle; the holes noted as usually facing east. Eggs, 5 or 6 (c/7-9 reported), pure white spherical ovals, glossy. Average size of 23 Kashmir eggs 25.8 × 21.9 mm (Osmaston). Both sexes share in digging the nest-tunnel and feeding the young; evidently also in incubation. Incubation period undetermined.
MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.; for description of plumages and structure (also bionomics), Witherby, 1938, 2: 263-5; for remarks on moult, Marion, JBNHS 49: 156.
MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail central outer
♂♂	144-156	37-44	12-14	108-120 87-96 mm
♀♀	136-148	—	—	—

(Witherby)

Weight 7 ♂♂ 45-56 (av. 49.7) g (Paludan).
COLOURS OF BARE PARTS. Iris crimson or red. Bill horny black. Legs and feet brown.

747. Bluecheeked Bee-eater. *Merops superciliosus persicus* Pallas

Merops persica Pallas, 1773, Reise Russ. Reich 2: 708 (Shores of the Caspian Sea)
Baker, FBI No. 1527, Vol. 4: 239
Plate 57, fig. 6

LOCAL NAMES. *Wādo trāklo* (Sind); *Bādā pātrings* (Hindi); *Haz rāgh* (= rain bird, Brahui); *Kerru* (Baluchi); *Bādā hājār-dā* (Kutch); *Mās pātrāngiyo* (Gujarati).
SIZE. Bulbul ±; length from tip of bill to tip of tail-pins c. 31 cm (12 in.).
FIELD CHARACTERS. A bright green bird with slender, slightly curved black bill and projecting pin-feathers in the tail. Readily distinguished from the commoner, more familiar Little Green Bee-eater (750) by larger size; a pale chestnut patch on throat; a broad black streak from base of bill backward through eye to ear-coverts; and a conspicuous white and blue-green cheek-patch below it. Rump and tail green (v. blue in 748). Sexes alike.
More 'stately' flight and sailing, rufous underwing, and call, further distinguish it from Little Green in the air.
STATUS, DISTRIBUTION AND HABITAT. Resident in small numbers locally in the more arid northwestern parts of the subcontinent, but numbers vastly augmented in summer by extralimital breeding visitors in West Pakistan (Baluchistan, Sind, northwestern Punjab) and NW. India (western Rajasthan, Saurashtra, Delhi). In some areas (e.g. NW. Punjab, Delhi and Dehra Dun (?)) breeding range overlaps with Bluetailed Bee-eater (748). Affects the neighbourhood of jheels and tanks and sandy seashores.
EXTRALIMITAL. Breeds elsewhere in Palestine, Iran, Transcaspia and W. Turkestan, south to Egypt and Iraq. Migrates over Arabia and the Nile Valley, wintering in tropical and southern Africa.

BEE-EATERS

105

Merops superciliosus persicus

Breeding range

MIGRATION. No ringing data. Observed as follows:

Gilgit. Passes through southward late in autumn — November (Scully, SF 10: 101).

Baluchistan. Arrives early April from a western direction, bulk follows later during the month or in early May; many remain to breed in coastal and central Makran and the Quetta area, others pass on eastward. Repasses through during the second half of August (Ticehurst, JBNHS 31: 878).

Sind. Arrives middle to late April or early May, apparently from a western direction. Some remain to breed others pass on, the passage sometimes continuing into early June. Return passage commences in late August or early September with many young birds in evidence; continues through October and early November (K. R. Eates, JBNHS 40: 756-9).

Kutch. Outward passage in September; inward not observed (SA).

Saurashtra. Arrives on the coast in May (Dharmakumarsinhji, JBNHS 46: 723-4).

Maharashtra (Bombay area). Passes through in April-May; repasses September-October, the flocks often mixed with the Bluetailed *M. philippinus* (SA).

Migrates during the night chiefly between the hours of dusk and dawn ('dusk to midnight and c. 4.30 to 9.30 a.m.' — Eates) in loose sprawling flocks. Passage high overhead in the dark revealed by the trilling contact calls of the birds. Evidently feeds and rests during daytime.

GENERAL HABITS. As in 746 (q.v.) and other bee-eaters. Keeps in pairs or small flocks near water — dhands or jheels, irrigation reservoirs and canals, etc. Invariably perches on telegraph wires where available. Launches out in the air every now and again in pursuit of winged insects, circling back

BEE-EATERS

107

Breeds in W. Pakistan in NW. Punjab (where breeding in some areas overlaps with 747) and northern India through Uttar Pradesh, Bihar, Bengal and Assam; patchily throughout the Peninsula south to Mysore. Also in Nepal (lowlands) and East Pakistan. Winters in the southern parts of its breeding range southward to Ceylon,¹ and in the Coco, Andaman and Nicobar Islands. Affects more wooded, less arid country than 747 and like it keeps to the neighbourhood of water — jheels, tanks, streams, coastal backwaters, etc.

x c. 1

Extralimital. Breeds elsewhere in Burma, Yunnan, Thailand, northern Malay Peninsula and the Indochinese countries. Winter visitor to the Indonesian islands and the Philippines.

GENERAL HABITS. Very similar to Bluecheeked Bee-eater (747). Loose flocks sometimes fly around over forest clearings hawking insects like swallows, or perch on the tips of tall trees and bamboos at the edge of forest whence to launch their aerial forays. On the West Coast the birds often hunt far out over estuaries and backwaters, considerable distances from land.

FOOD. Winged insects, mainly dragonflies, wasps and bees. Of the latter the following have been specifically identified in stomachs: *Apis indica* and *A. florea*, *Rhynchium bengalense*, *Sphex lobatus*, *Vespa orientalis*, *Polistes hebraeus*, the leaf-cutting bee *Megachile carbonaria* and the carpenter bee *Xylocopa discimilis* (Mason & Leisroy, 1912). On occasion also takes moths, beetles, bugs and bluebottle flies, *Musca vomitoria* (?). Predation on hive bees sometimes makes it a serious nuisance to bee-keepers.

VOICE AND CALLS. Close to the Little Green Bee-eater's (750) but louder and lower in key and unmistakable with it; more akin to the notes of the Chestnut-headed species.

BREEDING. Season, March to June, principally April and May. Nest, the usual tunnel in a vertical river bank or sandy cliff, usually up to 2 metres long. Nests colonially, often a hundred pairs or more together. Eggs, 5 to 7 normally 6, white, roundish ovals. Average size of 100 eggs 23.2 x 20.1 mm (Baker).

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.; for comments on moult, Marien, JBNHS 49: 150-1.

Differs from Bluecheeked Bee-eater (747) chiefly in its rump and tail being bright cerulean blue instead of bronze-green; whitish blue-green cheek-patch much smaller and less conspicuous; chestnut patch on throat and breast much larger and darker.

¹ Breeding recorded for the first time at Kumana, Eastern Province, April 1962 (C. E. Norris, JBNHS 60: 259).

106

CORACIIFORMES

gracefully to the base after each capture. Flight, as in other bee-eater, swift — a few rapid wing-beats followed by a glide.

FOOD. Dragonflies, bees, wasps (see under 748).

VOICE AND CALLS. Resembling those of the European Bee-eater (746), a musical interrogative *teew?* (repeated); in the distance sounding very much like the *pettigrew* of Redvented Bulbul (SA). These also used as contact calls during migration flight.

BREEDING. Season, April to August, principally May and June. Nest, the usual underground tunnel (1 to 2 metres long) burrowed in gently sloping sand dunes or mounds — sometimes almost flat ground — in semi-desert tracts, or in a shelving sandy seashore above tide mark; colonially, often up to a hundred pairs or more together, the holes scattered a metre or so apart. Eggs, 4 or 5, white, roundish ovals. Average size of 100 eggs 26.2 x 20.9 mm (Baker). Both sexes share in excavating nest-tunnel, incubation (?) and feeding the young. Incubation period undetermined.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.; for comments on moult, Marien, JBNHS 49: 150-1.

Differs from Bluetailed Bee-eater (748) chiefly in its rump and tail being more bronze-green less blue, and cheeks more conspicuously white and blue-green. Chestnut patch on throat and breast much smaller and paler.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail central outer
♂ ♀	146-160	35-44	11-12	135-148 86-90 mm (Baker)

6 ♂ ♀ ad. Wing 151-162 mm; weight 45-53 (av. 48.3) g (Paludan).

COLOURS OF BARE PARTS. Iris reddish brown to deep crimson. Bill horny black. Legs and feet fleshy plumbeous to dark brown.

748. Bluetailed Bee-eater. *Merops philippinus philippinus* Linnaeus

Merops philippinus Linnaeus, 1766, Syst. Nat., ed. 12, 1: 183, errata at end of volume; name for *Merops* 5th sp. (Philippine Islands)

Merops javanicus Horsfield, 1821, Trans. Linn. Soc. London 13 (1): 171 (Java)
Baker, FBI No. 1526, Vol. 4: 237
Plate 57, fig. 9

LOCAL NAMES. *Biddō pātrīnga* (Hindi); *Dorla* (Mirshikara, Bihar); *Jeta kasho* (Assamese); *Kompu pasteriki* (Telugu); *Viliññā* (Malayalam); *Shala* (Nicobares); *Kurumini kurullā*, *Nattūl kurullā*, *Ranillā*, *Ameyā* (Sinhala); *Kattālan kūrūn*, *Pā-chānkām* (Tamil).

SIZE. Same as Bluecheeked Bee-eater (747).

FIELD CHARACTERS. As of 747, q.v., but rump and tail bright blue, clearly seen in good light, especially in the flying bird. Sexes alike. See Museum Diagnosis.

Young (immature) paler and duller coloured than adult, especially on throat and breast.

STATUS, DISTRIBUTION AND HABITAT. Resident and locally migratory, frequently moving with Bluecheeked Bee-eater, but position very unclear.

749. *Merops orientalis beludschicus* Neumann

Merops viridis beludschicus Neumann, 1910, Orn. Monatsb. 18: 80
(Sarbae, Persian Baluchistan)
Baker, FBI No. 1525, Vol. 4: 236

LOCAL NAMES. *Nāndo trāklo*, *Atedan* (Sind).

SIZE. Sparrow ±; length bill-tip to tip of tail-pins c. 21 cm (8 in.).

FIELD CHARACTERS. As of 750, q.v. See Key to the Subspecies and Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident, subject to seasonal and altitudinal local movements. West Pakistan in Baluchistan (Makran, Sibi Plain, Quetta Valley (occasional; recorded November and January)), the Punjab districts, and Sind. Possibly extends into northern and western Rajasthan. Some Kutch and northern Gujarat examples are indistinguishable from this pale race (possibly migrants?). Affects open semi-desert country in the neighbourhood of cultivation, and grazing land.

Extralimital. Southeastern Iran.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in the Indian race (750).

BREEDING. Season, March to June, principally April and May. Nest and eggs (c/5 or 6) as in 750.

MUSEUM DIAGNOSIS. Much paler than the nominate subspecies of peninsular India (750); paler blue on throat and with merely a golden sheen on head and nape rather than rufous tint.

MEASUREMENTS

	Wing	Bill (from skull)	Tail
♂ ♀	91-95	29-32	{ 120-133 (♂) mm 100-114 (♀) mm

Central tail-feathers exceed outer by 51-63 mm in males, 33-43 mm in females (Ticehurst).

750. *Merops orientalis orientalis* Latham

Merops orientalis Latham, Index Orn., Suppl.: xxxiii (India = Pondichery side
Stresemann, 1952, Ibis 94: 515)
Baker, FBI No. 1523, Vol. 4: 234
Plate 57, fig. 10

LOCAL NAMES. *Pāringa*, *Hārīāl* (Hindi); *Bānpātī* (Bengal); *Tai lingi*, *Veda reghu*, *Pūtūr*, *Pūtēri* (Marathi); *Nāno pātāngiya* (Gujarati); *Chhēla hājāmdā* (Kutch); *Chinna passeriki* (Telugu); *Vēli tāttā* (Malayalam).

SIZE. Sparrow ±; length bill-tip to tip of tail-pins c. 21 cm (8 in.).

FIELD CHARACTERS. A slender grass-green bird tinged with reddish brown on head and hindneck, with the central pair of tail-feathers projecting as blunt pins beyond tail. Chin and throat verditer blue bordered below by a black gorget. Slender, long slightly curved black bill. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Resident, with marked seasonal local movements — withdrawing from wet areas during the monsoon and from northern areas in winter. Throughout the Indian subregion excluding W. Pakistan (*beludschicus*), eastern Assam (*birmanus*) and Ceylon (*ceylonicus*). Also occurs in Nepal, Sikkim and Bhutan at the lower elevations. Plains and up to c. 1500 m in the Himalayas and peninsular hills (to c. 2000 m in the Nilgiris). Affects open country interspersed with light forest and cultivation. Less tied up with the presence of water — ponds, jheels, etc. — than Blue-checked and Bluetailed Bee-eaters. On the seacoast shows a marked preference for the sandy zone immediately above high tide mark.

GENERAL HABITS. Keeps in loose parties and flocks of 15 to 20 or more, usually perched along telegraph wires, or on fence-posts and dead branches; frequently on the bare ground, sometimes on the backs of grazing cattle. Launches aerial sallies after winged insects, flying with a few rapid flaps followed by graceful swallow-like glides on open motionless wings. Snaps up the quarry in mid-air with an agile upward swoop and circles back to the base where it is whacked against the perch before being swallowed. Has communal roosts in leafy trees (e.g. neem — *Melia*) or bamboo clumps, where large numbers congregate at sunset. Much noise and bustle prevail before the birds finally retire for the night. There is constant bickering and supplanting of occupants of coveted perches in the centre of the huddled rows, and every now and again for no apparent reason the entire concourse 'explodes' to fly around in a confused rabble, accompanied by much excited trilling, the birds gradually settling again. Is a late riser and frequently to be seen in the mornings clumped in little groups along the perch, all facing the same way, head tucked under the wing, fast asleep till well after sunrise. Is fonder of dust-bathing than its larger congeners (747-8), which bathe chiefly by dipping in water on the wing.

FOOD. Mainly Hymenoptera — ants, bees and wasps; also moths, butterflies, small beetles (e.g. *Myllocerus* spp.), dragonflies, termites, and other winged insects. In bee-keeping districts preys largely on the two common

BEE-EATERS

111

STATUS, DISTRIBUTION AND HABITAT. Eastern Assam east of Cachar; lowlands.

EXTRALIMITAL. Burma (including Shan States), Yunnan, Thailand, Indo-Chinese countries (excluding North Vietnam) — Peters.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 750.

BREEDING. Season, chiefly April and May. Nest and eggs, as in 750 but 'full clutch seems to be 5 more often than 6' (Baker).

MUSEUM DIAGNOSIS. Differs from the nominate Indian subspecies (750) in having the upper head, hindneck and upper back ferruginous; the upper plumage is generally darker and the flanks more ferruginous.

MEASUREMENTS

Wing ♂ ♀ 93-99 mm (Baker).
COLOURS OF BARE PARTS as in 750.

752. *Merops orientalis ceylonicus* Neumann

Merops orientalis ceylonicus Whistler, 1944, Spolia Zeylanica 23: 223
(Kallawewa, Ceylon)
Baker FBI No. 1523 (part), Vol. 4: 234

LOCAL NAMES. *Kurumim kirillā* (Sinhala); *Kattālen kiriri*, *Penchānkam* (Tamil).

SIZE. Sparrow ±; length bill-tip to tip of tail-pins c. 21 cm (8 in.).

FIELD CHARACTERS. As of 750, q.v. See Key to the Subspecies and Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Common resident. Widely distributed and abundant throughout the low-country Dry zone (under c. 300 m), especially in the sandy tracts round the coast in the northwest and south-east. Affects the same biotope as in the Peninsula.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 750.

BREEDING. Season, April to July, chiefly during June and July. Nest and eggs as in the Indian bird.

MUSEUM DIAGNOSIS. Not very distinct from peninsular birds (750) but in a comparable series shows a more pronounced golden tinge on nape and hindneck; throat and moustachial streak bluer; black gular band wider and heavier; bill stouter and longer.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail (central)
9 ♂ ♂	92-95	34-36	9-10	114-138 mm
2 ♀ ♀	91	33, 34	10	108 mm (HW)

Weight 1 ♂ 17 g (SDR).

COLOURS OF BARE PARTS. As in 750.

Genus NYCTYORNIS Jardine & Selby

Nyctyornis Swainson MS., Jardine & Selby, 1830, Ill. Orn. 2, Addenda, sign. D2
Type, by diagnosis, *Merops ericta* Temminck

Feathers of throat and centre of breast greatly lengthened and brightly coloured. Bill stronger and deeper than in *Merops*; ridge of culmen flattened, with a hollow on either side; nostrils covered by plumes. Wings long: first primary (as.) about two-thirds length of third which is the longest. Tail long, slightly graduated, with the central feathers not attenuated or projecting.

CORACIIFORMES

110

hive bees *Apis indica* and *A. florea*, thus sometimes becoming a serious nuisance.

VOICE AND CALLS. A pleasant jingling tree-tree-tree or teep-teep-teep etc. punctuated from time to time by a tit-tit-tit; uttered chiefly on the wing, but also while perched.

BREEDING. Season, overall February to June varying locally. Nest a tunnel c. 3-4 cm in diameter bored horizontally in an earth mound or sandy cutting, or in the sides of a borrow-pit and the like; often driven obliquely in almost flat sandy ground, singly or in a scattered colony. Tunnels usually from half a metre to two metres long ending in a widened egg-chamber; unlined but often littered with chitinous insect remains. Eggs, 4 to 7, commonly 6, pure white roundish ovals. Average size of 100 eggs 19.3 × 17.3 mm (Baker). From the marked disparity in growth of young in the same brood, eggs possibly laid at longer intervals than 24 hours, incubation commencing from the first egg. Apparently both sexes incubate as they also tend the young. Incubation period undetermined.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

Post-juvenal moult complete. No spring moult, and post-nuptial moult complete. Wear turns many green feathers blue, especially the tertiaries.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail (central)
♂ ♂	92-99	28-33	9-10	112-141 mm
♀ ♀	91-94	30-33	8-10	(84) 107-126 mm (SA, HW)
		(from feathers)		(outer)
♂ ♂	89-97 (av. of 20, 93.6)	20-25 (av. of 25, 23.2)	—	68-74 mm (av. of 19, 71.2)
♀ ♀	89-95 (av. of 22, 91.4)	19-26 (av. of 27, 22.6)	—	65-74 mm (av. of 24, 70.4) (Marien)

Weight 1 ♂ 18 g (Rensch); 1 ♀ 15 g (SA).

COLOURS OF BARE PARTS. Iris claret or crimson. Bill brownish black; mouth pink. Legs and feet yellowish brown; claws horny brown.

751. *Merops orientalis birmanus* Neumann

Merops viridis birmanus Neumann, 1910, Orn. Monatsb. 18: 80
(Myingyan [= Myingyan], Irawaddy River, Burma)
Baker, FBI No. 1524, Vol. 4: 236

LOCAL NAME. *Hārīāl sorāi* (Assam).

SIZE. Sparrow ±; length bill-tip to tip of tail-pins c. 21 cm (8 in.).

FIELD CHARACTERS. As of 750, q.v. See Key to the Subspecies and Museum Diagnosis.

CORACIIFORMES

112

753. Bluebearded Bee-eater. *Nyctyornis athertoni athertoni* (Jardine & Selby)

Merops athertoni Jardine & Selby, 1830, Ill. Orn. 2, pl. 58 and text (India = Bangalore)
Bucia nipalensis Hodgson, 1836, Jour. Asiat. Soc. Bengal 5: 361 (Nepal)
Nyctyornis athertoni barlettii Koelz, 1954, Contrib. Inst. Regional Exploration, No. 1: 25 (Keitum, Lushai Hills)
Baker, FBI No. 1529, Vol. 4: 242
Plate 57, fig. 5

LOCAL NAMES. *Bukay chera* (Nepal); *Sang rhyak* (Lepcha); *Deo hukuru* (Cachari); *Kāttu rēlittāttā* (Malayalam).

SIZE. Pigeon ±; slimmer. Length c. 36 cm (14 in.).

FIELD CHARACTERS. A large green bee-eater with long, slender, slightly curved black bill. Above, grass-green with pale greenish blue forehead. Below, middle of throat and of the deep verditer upper breast light blue, the feathers lengthened and forming the 'beard' which is conspicuous in profile especially when the bird is calling. Rest of underparts reddish buff streaked with broad green shaft-stripes. Tail square-cut with no projecting pin-feathers; looks triangular in flight like Large Green Barbet's. Sexes alike.

x.c.1

STATUS, DISTRIBUTION AND HABITAT. Resident; local and scattered. The Lower Himalayas (westernmost records, specimens, from 'Kalesar forest, SE. Punjab' and Kotgarh, H.P. [c. 31°18'N., 77°29'E.] — H. W. Waite, JBNHS 39: 861). Normally in the terai, bhabar, duns and duars and up to c. 1700 m, from about Dehra Dun eastward through U.P., Nepal, Sikkim, Bhutan; also Assam north and south of Brahmaputra river, Nagaland, Manipur, Mizo and East Pakistan. The Western Ghats complex (to c. 1700 m in the Nilgiris) from Khandesh southward through Surat Dangs (?), Maharashtra, western Mysore, western Tamil Nadu and Kerala. Andhra, Madhya Pradesh, Orissa, Bihar and W. Bengal. Affects secondary evergreen and moist-deciduous forest biotope, especially broken foothills country with overgrown ravines etc.; occasionally forest clearings with a few scattered trees.

EXTRALIMITAL. Burma, Thailand, and the Indochinese countries. Also Hainan Island (subspecies?).

GENERAL HABITS. Arboreal. Rather sluggish compared to the smaller bee-eaters. Usually keeps in pairs and is very shy, rarely returning to the same place whence disturbed. Launches aerial sallies after passing insects

ROLLERS OR BLUE JAYS 113

from a look-out post in a leafy tree-top, sailing back to its base after each capture and battering the victim against the perch before swallowing it. Flight steeply undulating, very like Large Green Barbet's — a few flaps followed by a downward dip with wings closed.

FOOD. Insects, chiefly bees, wasps, dragonflies and beetles. Has been occasionally observed at nectar-bearing flowers, e.g. *Erythrina* and *Salmalia* (for nectar or insects?).

VOICE AND CALLS. Hoarse guttural croaks or chortles *kor-r-r, kor-r-r*, etc. reminiscent of the notes that preface the *kutroo* calls of the Green Barbet (780-82), but deeper in tone. Not specially loud, but audible at a surprising distance. When calling the 'beard' stands away conspicuously from the throat and breast.

BREEDING. Season, overall February to August, varying locally; chiefly April and May. Nest, a horizontal tunnel c. 5 to 6 cm in diameter and 1.5 to 3 metres long bored into precipitous outcoursed alluvial banks of forest ravines and streams, or in landlips and roadside cuttings in hilly country; sometimes 6 to 8 metres up the face, at others fairly low down. Tunnel ends in a widened egg-chamber, unlined but usually littered with a quantity of chitinous insect remains which also get copiously scattered outside below the entrance-hole. Eggs, 4 to 6, pure white, roundish and with a fair gloss — closely resembling those of Whitebreasted Kingfisher (736). Average size of 50 eggs 30 × 28 mm (Baker).

Excavation often commences a month or more before actual laying of eggs. Both sexes take part, and later also in incubation (?) and feeding the young. Incubation period undetermined.

Snakes frequently take refuge in the nests, therefore caution is recommended when inserting the hand to examine the contents — *experto crede!*

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

Young (immature) exactly like adult in plumage only somewhat smaller in size and with usually a shorter bill.

Has a single complete moult (post-nuptial) between May and October. Post-juvenal moult occurs about the same time (Marien, JBNHS 49: 164).

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	133-143	50-56	18-19	127-137 mm
♀♀	132-140	47-57	18-19	127-137 mm (SA, HW, BB)

Weight 2 ♂♂ 85, 93 g; 1 ♀ 84 g (SA, Paynter).

COLOURS OF BARE PARTS. Iris bright golden orange. Bill horny brown, grey at chin and on basal half of lower mandible; mouth greyish pink. Legs and feet pale yellowish sage-green; claws horny brown.

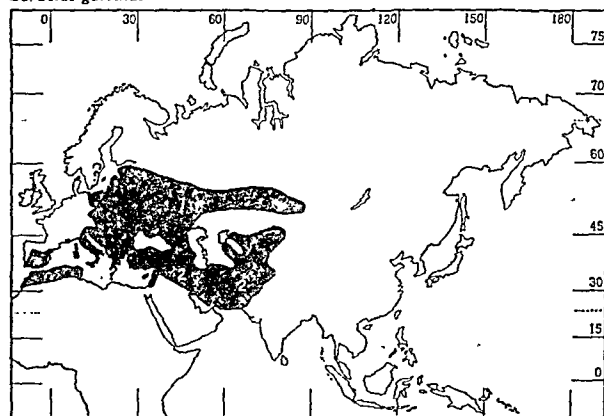

Family CORACIIDAE: Rollers or Blue Jays

For description see Van Tyne, J., and Berger, A. J., 1959: 474; Baker, E. C. S., 1927, FBI 4: 221; Thomson, A. L., 1964, Article 'Roller', *New Dict. Birds*, London & New York.

8

ROLLERS OR BLUE JAYS 115

Coracias garrulus

■ Breeding range x *C. g. garrulus* (RE). a *C. g. semenowi* (754).

MIGRATION. No ringing data. In spring arrives in N. Baluchistan, Peshawar district, Chitral, Gilgit and Kashmir between end March and May, the majority of birds passing through, some remaining to breed. Return (autumn) passage through these areas occurs in August-September. Plentiful on autumn passage in an ENE.-WSW. direction through Sind, Punjab (Lahore dist.), Rajasthan, Kutch and northern Gujarat between mid August and early October. Spring passage evidently follows a different route by-passing these areas. Not noted in Kutch at that season, nor in Sind 'except, only once, on 14 May' (Ticehurst).

Migrates during daytime, chiefly in the morning before noon, but also later throughout the day. The birds travel individually in a steady stream, strung out one behind another at about half-minute intervals over a very wide front, flying at a height of 100 to 150 metres with unhurried purposeful wing-beats.

GENERAL HABITS. Met with singly or in pairs perched on telegraph wires, posts or dead trees commanding an uninterrupted view of the surroundings. Pounces on quarry on the ground either disposing of it on the spot or flying back with it to the perch. Habits largely as of the Northern Roller (755, q.v.) including the extravagant noisy acrobatic nuptial display. Flight rather sluggish, with deliberate wing-strokes very like a crow's in silhouette.

FOOD. Beetles, mole crickets (*Gryllotalpa*), grasshoppers and other large insects taken on the ground; occasionally in the air. Also lizards and frogs, the latter forming a considerable proportion of the food brought to the young.

VOICE AND CALLS. Harsh grating screams uttered chiefly during the aerial display; occasionally from perch. Birds very noisy in breeding season:

Key to the Genera

	Page
Bill compressed; breadth at gape about half the length of culmen.....	114
Bill short, broad and swollen at base; breadth at gape about equal to culmen.....	120

Genus CORACIAS Linnaeus

Coracias Linnaeus, 1758, Syst. Nat., ed. 10, 1: 107. Type, by subsequent designation, *Coracias garrulus* Linnaeus

Bill rather long, compressed, and with the culmen slightly curved; nostrils elongate and exposed; gape with strong rictal bristles.

The genus extends throughout Europe and a great part of Asia and Africa.

Key to the Species

Lower plumage pale blue throughout.....	<i>C. garrulus</i>	114
Breast rufous, abdomen and lower tail-coverts blue....	<i>C. benghalensis</i>	116

754. Kashmir Roller. *Coracias garrulus semenowi* Loudon & Tschudi

Coracias garrulus semenowi Loudon & Tschudi, 1902, Orn. Jahrb. 13: 148 (Transcaspia)

Baker, FBI No. 1516, Vol. 4: 222

Plate 57, fig. 8

LOCAL NAMES. *Nilā krāsh* (Kashmir); *Sābkhārāk* (Brahui); *Kashmiri nilkāt* (Gujarat).

SIZE. Pigeon; length c. 31 cm (12 in.).

FIELD CHARACTERS. A brightly coloured bird, chiefly blue and brownish rufous, with biggish head and stout bill. Easily distinguished on the wing from the commoner 'Blue Jay' by its blue-black flight feathers (v. banded dark-and-light blue) and by its uniformly light blue breast and underparts (v. blue restricted to abdomen and vent). Sexes alike.

Young (immature) like adult but paler and duller. Wing-quills tipped browner; the blue of the coverts dull and pale.

STATUS, DISTRIBUTION AND HABITAT. Breeds in Baluchistan (?), NW F. districts of W. Pakistan, Gilgit, and Kashmir between c. 1700 and 2200 m altitude (straggler recorded at c. 3200 m). Migrates to Arabia and presumably Africa in autumn, commonly passing through Sind, Rajasthan and northern Gujarat (Kutch, Saurashtra). Occasionally straggling, then as far east as Seoni dist. in Madhya Pradesh (Lakhnad on 79°30'E.—SA) and south through Maharashtra (Dhulia, Khandala, Bombay) to Mysore (Karwar, 14°50'N.). In its Indian breeding range affects lightly wooded parkland and cultivated areas such as are characteristic of the Vale of Kashmir.

Extralimital. Breeds also in Transcaspia, Turkestan, and the western Tien Shan south to Iran (thence westward to Iraq and perhaps the Jordan Valley (Peters)). Winters in Arabia; possibly also in Africa though this subspecies not yet proven there *vide* Meinertzhagen (1954: 296).

8

116 CORACIIFORMES

BREEDING. Season, chiefly May to July. Nest, a natural hollow in an ancient poplar, willow or chenar tree, or in a clay or conglomerate cliff. Unlined, but often bestrewn with chitinous remains of beetles etc. Eggs, 5 or 6, pure white, glossy, rather elongate ovals; sometimes speckled with small brown spots of unknown origin easily removed by washing. Average size of 16 Kashmir eggs 36.3 × 29.0 mm (Osmaston). Both sexes incubate and feed the young; incubation period undetermined; in nominate race 18-19 days (Witherby). When one bird is brooding its mate keeps guard nearby, swooping with harsh grating squawks at intruders into the proximity.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.; for description of plumages and structure (also bionomics) of the nominate (European) race, Witherby, 1938, 2: 269-72. Differs from the latter in being paler coloured above and below. Frontal feathers almost white; underparts paler, blue rather than greenish blue. More easily distinguished in juvenile and adult winter plumage. 'The lateral pair of tail-feathers fall short of the middle pair by 17-24 mm. It migrates through in its juvenile dress' (Ticehurst).

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂♀	180-210	30-35 (from feathers)	25-26	122-135 mm (Baker)

Weight 1 ♂ 164, 1 ♀ 120 g (SA).

Kashmir birds, *vide* Baker, are very large compared with those from Iran, Afghanistan, Baluchistan and Punjab.

COLOURS OF BARE PARTS. Iris pale brown to hazel brown. Bill brownish black to black. Legs and feet dull yellow.

ROLLERS OR BLUE JAYS

117

SIZE. Pigeon; length c. 31 cm (12 in.).

FIELD CHARACTERS. A striking Oxford-and-Cambridge blue bird with biggish head, heavy rather crow-like bill, rufous-brown coloured breast, and pale blue abdomen and vent. An obsolete reddish brown collar on hind-neck. In flight the dark and pale blue portions of the wings flash as brilliant bands. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Resident, subject to little understood seasonal local movements; common. West Pakistan (Baluchistan, Sind, Punjab) and all continental India along the Himalayan submontane tract (up to c. 1500 m — Dharmasala; Garhwal). A specimen collected at c. 3700 m in NW. Nepal (Lowndes, JBNHS 53: 36), and one in Bhutan at c. 2500 m (Ludlow, 1937, *Ibis*: 487) eastward through Nepal, south through the plains to an arbitrary boundary at 20°N. latitude where it intergrades with *indica*. Intergrades with *affinis* in Nepal east of c. 85°E. longitude, NE. Bihar, Sikkim, northern and eastern Bengal, and W. Assam (Garo Hills). Affects open cultivation, gardens, groves of mango and other trees near villages; also light deciduous forest.

Extralimital. Eastern Arabia, southern Iran, Iraq.

GENERAL HABITS. Keeps singly or in pairs perched on telegraph wires, fence posts, earth clods in ploughed fields, and bare trees commanding a clear view of the surroundings and movements of creeping prey. On perch, swings tail slowly up and down as in Blackwinged Kite, Forest Wagtail and Little Green Bee-eater. Pounces lazily — almost parachutes — down to the ground from time to time to seize its quarry, disposing of it on the spot or flying leisurely with it back to the same perch or across to another nearby where the victim is battered before swallowing. Has been observed to pick up small fish neatly from near surface of water (SA) and occasionally to plunge for it like a kingfisher, completely submerging for a moment (Delme-Radcliff, JBNHS 20: 225; Dalglish, *ibid.* 20: 853; Tiwary, *ibid.* 34: 578). This evidently an individual idiosyncrasy. Has a very noisy and spectacular display during the breeding season, sometimes both birds of a pair participating. The bird rockets up in the air vertically, flaps about erratically in steep wave-crests and performs a series of fantastic evolutions — tumbling, somersaulting, nose-diving, looping the loop and rolling from side to side to the accompaniment of loud raucous screams, its brilliant plumage flashing in the sun. These extravagant antics and playful dives sometimes directed at quietly perched female, at other times apparently in self-exhilaration.

FOOD. Largely insects — beetles, locusts, crickets — sometimes (e.g. moths, winged ants and termites) taken in the air. Also frogs, lizards, occasionally small snakes and field mice, and rarely even young birds. Scorpions also recorded. Among stomach contents analysed at Pusa (Bihar) the following insects were frequently recorded: *Gryllotalpa africana*, *Gryllodes melanoccephalus*, *Myrmecocystus selipes*, *Chrologonus* spp., ants (*Camponotus compressus*), and beetles and grubs of various kinds (*Trox*, *Opatrum*, etc.). Is, on balance, a highly beneficial species to agriculture by virtue of the vast

Left foot, x c. 1

ROLLERS OR BLUE JAYS

119

STATUS, DISTRIBUTION and HABITAT. Resident, with some local movement. Common. Indian peninsula south of 20°N. lat. (around which it intergrades with *benghalensis* [755]), and Ceylon; low country and locally up to c. 1000 m. Laccadive Is. (Burton, JBNHS 41: 597). Maldives Is. (Gan, Addu Atoll, November 1968 — Flt Lt J. L. Gregory, *in epist.*). Affects open cultivation, groves of trees in the neighbourhood of habitations, and light forest — in deciduous biotope.

GENERAL HABITS, FOOD, VOICE and CALLS. As in the Northern Roller (755).

BREEDING. Season, in South India (e.g. Kerala) January to March/April; in Ceylon March to June, chiefly March and April. Nest and eggs as in 755. Average size of 24 eggs from Kerala and Ceylon given by Baker as 35.2 × 27.7 mm.

MUSEUM DIAGNOSIS. Differs from *benghalensis* in being slightly smaller, darker and more greenish above, with a deeper-coloured more pronounced nuchal collar.

MEASUREMENTS	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	170-190	41-49	24-26	109-132 mm (SA, HW)

COLOURS OF BARE PARTS. As in 755.

757. *Coracias benghalensis affinis* Horsfield

Coracias affinis Horsfield, 1839 (1840), Proc. Zool. Soc. London pt. 7: 164 (Assam) Baker, FBI No. 1519, Vol. 4: 226

LOCAL NAMES. *Kabrar*, *Konsa* (Assam); *Das galang* (Cachari); *Takral* (Lepcha).

SIZE. Pigeon; length c. 31 cm (12 in.).

FIELD CHARACTERS. As of 755, q.v. See Key to the Subspecies and Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident, subject to seasonal local movements; common. Nepal, Sikkim, Bhutan, Assam, Nagaland, Manipur, Mizo (?), East Pakistan. Plains, duars and foothills to c. 600 m.

Intergrades with *benghalensis* in Nepal (around c. 85°E. long.), NE. Bihar, Sikkim, northern and eastern Bengal and western Assam (Garo Hills).

Affects cultivation, light forest and clearings.

Extralimital. Burma south to Tenasserim, Yunnan, Thailand, Indo Chinese countries.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 755.

BREEDING. Season, principally April and May. Nest and eggs as in 755. Average size of 30 eggs 34.7 × 27.9 mm (Baker).

MUSEUM DIAGNOSIS. Much darker and deeper coloured than *benghalensis* or *indica*. Under wing-coverts deep purple-blue; rufous-brown underparts with a strong purplish blue flush; streaks on throat brilliant small-blue instead of whitish; pale blue on underparts confined to vent and under tail-coverts.

MEASUREMENTS	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	184-204	30-36	26-28	118-137 mm (Baker)

118

CORACIIFORMES

quantities of insect pests it destroys. (For details of food items see Mason & Lefroy, 1912: 155-7.)

VOICE and CALLS. A loud, raucous *kāl* (or *chāk*)-*kāk-kāk-kāk* etc. uttered from a perch; varied and drawn out into excited discordant screeches and shrieks during aerial display, and by way of 'war cries' when chasing off intruders in its territory. 'Independently-hunting young birds mew like cats' (Mrs M. D. Wright).

BREEDING. Season overall March to June/July, principally March and April. Nest, an untidy collection of grass, straw, rags and rubbish in a natural hollow in a rotten tree-trunk or bough at moderate heights, or in the trunk of a palmyra palm; sometimes in a hole in the outer wall or under the roof of a dilapidated building. Eggs, 3, sometimes 4, rarely 5; pure white, glossy, roundish ovals. Average size of 50 eggs 34.3 × 28.1 mm (Baker). Both sexes incubate and feed the young; incubation period 17-19 days, mostly 18. (B. S. Lamba).

MUSEUM DIAGNOSIS. See Key to the Subspecies; for details of plumage, Baker, loc. cit.

MEASUREMENTS	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	178-201	39-49	25-29	117-140 mm (HW, SA, BB)

Weight 1 ♂ 166 g; 2 ♀ 166, 176 g (Paynter).

There is no consistent difference in the size of the sexes, but in keeping with the normal trend (Bergmann's Rule) a gradual increase in size from south to north.

COLOURS OF BARE PARTS. Iris brown; rim round eye dull orange. Bill brownish black; mouth sulphur-yellow and pink. Legs and feet dirty brownish yellow; claws black.

756. *Coracias benghalensis indica* Linnaeus

Coracias indica Linnaeus, 1766, Syst. Nat., ed. 12, 1: 159

(East Indies = Ceylon, ex Edwards)

Baker, FBI No. 1518, Vol. 4: 226

LOCAL NAMES. *Tās*, *Chāsh* (Marathi); *Pālā pītā* (Telugu); *Kāttu kadri*, *Pāl kūrūri* (Tamil); *Panamkākkā* (Malayalam); *Dunkāwa*, *Dunkāwulwā*, *Dumbonā* (Sinhala); *Panamkādai*, *Kōttai-kili* (Tamil — Ceylon).

SIZE. Pigeon; length c. 31 cm (12 in.).

x c. 1

FIELD CHARACTERS. As of 755, q.v. See Key to the Subspecies and Museum Diagnosis.

120

CORACIIFORMES

COLOURS OF BARE PARTS. Iris brown; edge of eyelids and bare skin in front and behind eye orange-yellow. Bill almost black. Legs and feet dull yellowish brown (Baker).

Genus EURYSTOMUS Vieillot

Eurystomus Vieillot, 1816, Analyse: 37. Type, by monotypy, *Rolle des Indes*, Buffon = *Coracias orientalis* Linnaeus.

Cf. Ripley, S. D., 1942, Proc. Biol. Soc. Washington 55: 169-76

Meise, W., 1950, Jour. Bombay nat. Hist. Soc. 49: 305-6

Deraniyagala, P. E. P., 1951, Spolia Zeylanica 26: 155-7

Bill short, broad, and very stout; width at gape about equal to length of culmen; terminal quarter compressed; upper mandible strongly hooked. Nostrils exposed; no rictal bristles. Wing long and pointed: 2nd primary (as.) longest. Tail almost square.

EURYSTOMUS ORIENTALIS (Linnaeus): BROADBILLED ROLLER

Key to the Subspecies

Eurystomus orientalis aburdu Ripley, 1942, Proc. Biol. Soc. Washington 55: 170 (Nanking, China). New name for *colonyx* Sharpe

Baker, FBI No. 1520 (part), Vol. 4: 228

Plate 57, fig. 12

LOCAL NAMES. *Tek rel song* (Lepcha); 'Dollar Bird' (English, substantive).

SIZE. Pigeon; length c. 31 cm (12 in.).

FIELD CHARACTERS. A dark greenish brown and purple blue-black Roller with blackish head and very broad orange-red bill and legs. A large pale blue roundish patch on wing (the 'dollar') particularly conspicuous in flight. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Resident; not common. The Himalayan submontane tract normally from Garhwal (westernmost record Ambala dist. [Waite, JBNHS 39: 861]) eastward through Nepal, Sikkim, Bhutan and NEFA; Assam, Nagaland, Manipur, East Pakistan. From plains level (terai, duars and duns) to c. 1000 m. Affects heavy secondary tropical

Bill from above, x c. 1 (After Hartley)

121

evergreen jungle, and forest clearings for cultivation with scattered standing trees.

Eurystomus orientalis

E. o. cyanicollis (758).
 E. o. laetior (759).
E. o. irisi (760).
 E. o. gigas (762).

Distributional range

Extralimital. Northern Burma northward to the lower Amur (Siberia) and Manchuria. South in winter to Malay Peninsula, Thailand, Indochinese countries, S. China, Japan, and many Indo-Malaysian islands.

GENERAL HABITS. Keeps singly or in pairs — occasionally small loose parties — to heavy forest or its immediate environs (clearings etc.) perched on the topmost branches of tall dead trees for long periods. Makes short sorties now and again after passing insects, performing curious evolutions in mid-air in their pursuit and usually returning to its base after each capture.

× c. 1

Less sluggish than Blue Jay, and markedly crepuscular. Active in the morning and evening, commonly hunting till late into the dusk. Takes insects on the wing; occasionally pounces on creeping prey on the ground. Flapping flight more rapid and direct than Blue Jay's. Follows insects, e.g. winged termites, to considerable heights, hawking in wide circles — a few deliberate wing-flaps followed by long stretches of gliding. Has a spectacular aerial nuptial display similar to the Blue Jay's (755) q.v.,

ROLLERS OR BLUE JAYS

123

MEASUREMENTS	Wing	Bill (from skull)	Tarsus	Tail
6 ♂♂	194-205	33-36	19-21	99-106 mm (HW, SA)

COLOURS OF BARE PARTS. Iris brown. Bill orange-red, blackish brown at tip; palat and gape pale sulphur-yellow, gullet greyish pink. Legs and feet orange-red or coral-red; claws blackish brown (SA).

760. *Eurystomus orientalis irisi* Deraniyagala

Eurystomus orientalis irisi Deraniyagala, 1951, Admin. Rept. of the Dir. Nat. Museums, Ceylon, for 1950, Pt. iv, Educ., Sci. and Art (E): E14 (Maha-oya, Ceylon) Baker, FBI No. 1520 (part), Vol. 4: 228

LOCAL NAMES. *Pūlappōrūkki* (Tamil); *Kes kaunda* (Sinhala).

SIZE. Pigeon; length c. 31 cm (12 in.).

FIELD CHARACTERS. As in 758. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Very rare resident; nearly extinct. In all only about twelve records known from the Island in a century or more, the latest after a lapse of 60 years. This, a breeding pair, possibly two of the very last birds in existence, was shot by an unspeakable museum collector in February 1950, since when no more have been reported!

GENERAL HABITS, FOOD, VOICE AND CALLS. Not recorded; presumably as in 758 and the Kerala subspecies.

BREEDING. *Sedon*, 'February and March' (Phillips).

MUSEUM DIAGNOSIS. Differs from the Kerala population only in having a shorter wing; no difference in coloration.

MEASUREMENTS	Wing	Tarsus	Tail
4 o? Wing 178-188 mm; Bill (from skull) 29-30 mm (Meise, SA).			
1 ♂	182*	18	98 mm
1 ♀	180	17	97 mm (Deraniyagala)

COLOURS OF BARE PARTS. As in 759.

762. *Eurystomus orientalis gigas* Stresemann

Eurystomus orientalis gigas Stresemann, 1913, Novit. Zool. 20: 297 (in key), 299 (Rutland Island, Andaman Islands) Baker, FBI No. 1521, Vol. 4: 231

LOCAL NAMES. None recorded.

SIZE. Pigeon; length c. 31 cm (12 in.).

FIELD CHARACTERS. As in 758. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident; fairly common and widely distributed: Andaman Islands including Narcondam. Affects clearings in high evergreen forest.

122

CORACIIFORMES

consisting of shooting vertically skyward and nose-diving in steep wave-crests, rolling from side to side, and other fantastic acrobatics kept up for several minutes at a time.

FOOD. Chiefly insects: crickets, beetles, flying termites, etc. Also lizards, and doubtless other small animals.

VOICE AND CALLS. On the whole very silent. Occasionally utters a raucous *chack-chack* repeated every second or two, alternated from time to time by a quicker-repeated chattering croak *chack-chack-chack*.

BREEDING. *Season*, March to May. *Nest*, an unlined natural hollow, or a barbet- or woodpecker hole in a lofty tree-trunk (such as *Salmaia* or *Tetra-*meles**) standing near the edge or in the midst of a forest clearing, frequently 15 or 20 m up. The same hole is often occupied in successive years, but whether by the same or a different pair is unproven. *Eggs*, 3 or 4, white spherical ovals measuring c. 36 × 28 mm. Both sexes incubate and feed the young; period of incubation undetermined.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.; for subspecies Key.

MEASUREMENTS	Wing	Bill (from skull)	Tarsus	Tail
8 ♂♂	178-198	27-33	20 (1)	93-102 mm
6 ♀♀	184-196	30-35	—	90-100 mm (BB, SA)

Weight 1 ♀ (March) 172 g; 1 ♂ (August) 120 g — Paynter.

COLOURS OF BARE PARTS. Iris dark brown; edges of upper eyelid and orbital skin dusky vermilion. Bill, legs and feet deep vermilion with black on tip of bill; claws black; soles vermilion (Biswas).

759. *Eurystomus orientalis laetior* Sharpe

Eurystomus laetior Sharpe, 1890, Proc. Zool. Soc. London: 551 (Forests of Malabar, the Nilgiris and Ceylon, restricted to Eridge, Travancore) Baker, FBI No. 1520 (part), Vol. 4: 228

LOCAL NAMES. *Pūlappōrūkki* (Tamil); *Kattu pānamkalka* (Malayalam).

SIZE. Pigeon; length c. 31 cm (12 in.).

FIELD CHARACTERS. As in 758. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident; rather rare and patchily distributed: Kerala north to Wynad (Malabar dist.); W. Mysore (Coorg dist.) and western Tamil Nadu (Nilgiri dist.). Affects cultivation clearings in heavy evergreen and semi-evergreen forest, neglected overgrown rubber and coffee plantations, etc.; low country and foothills up to c. 500 m.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in the Himalayan subspecies (758), q.v.

BREEDING. *Season*, September to May, chiefly March and April. *Nest*, eggs, and breeding biology as in 758.

MUSEUM DIAGNOSIS. Differs from the disjunct Himalayan population *cyanicollis* (758) in being a brighter, more intense blue on the underparts, with a markedly blacker head (crown and face).

CORACIIFORMES

124

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 758 and other races, qq.v. **BREEDING.** Unrecorded.

MUSEUM DIAGNOSIS. Differs from Himalayan *cyanicollis* (758) only in having a much larger bill; also slightly larger measurements. No difference in coloration.

MEASUREMENTS	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	184-205	27-30	c. 21	106-112 mm (Baker)
		(from skull)

1 ♀	199	35	19	103 mm (Grubb)

Weight 1 ♂ 165 g; 1 ♀ 145 g (Grubb).

COLOURS OF BARE PARTS. As in 758 and other races.

Family UPUPIDAE: Hoopoes

For description see Van Tine, J., and Berger, A. J., 1959: 476; Stresemann, E., 1927-34, *Aves*: 831-2; Baker, E. C. S., 1927, FBI 4: 307; Thomson, A. L., 1964, Article 'Hoopoe', *New Dict. Birds*, London & New York.

Genus UPUPA Linnaeus

Upupa Linnaeus, 1758, Syst. Nat., ed. 10, 1: 117. Type, by monotypy, *Upupa epops* Linnaeus

An ample erectile fan-shaped crest with the posterior feathers longest. Bill long, slender and decurved from the base; tongue very short. Wing rounded, of 10 primaries. Tail moderately long; 10 rectrices only. Tarsus short, scutellated behind; foot imperfectly syndactyle, 3rd and 4th toes joined at the base.

UPUPA EPOPS Linnaeus: HOPOOE

Key to the Subspecies

Upupa Epops Linnaeus, 1758, Syst. Nat., ed. 10, 1: 117 (*Europae tyritus* = Sweden) Baker, FBI No. 1579, Vol. 4: 308 Plate 58, fig. 14

LOCAL NAMES. *Hāhād* (Hindi); *Satut* (Kashmir); *Sikāḍū* (Himachal Pradesh); *Māgh-i-Sulimān* (Baluch); *Kāḍḍo* (Sind); *Lacher ghak* (Punjab); *Khetile*, *Nēz* (Madhya Pradesh); *Seem kōrka* (Halbi, Bastar Dist.).

SIZE. Myna; length c. 31 cm (12 in.) to tip of long slender bill.

HOOPES

125

FIELD CHARACTERS. A fawn coloured bird with prominent black-and-white zebra markings on back, wings and tail. A prominent black-and-white-tipped crest, full and fan-shaped when erected, falling to a point behind the head when folded. Long, slender, gently decurved bill. Sexes alike.

Young (immature) duller and paler above, browner below.

STATUS, DISTRIBUTION and HABITAT. Resident or breeding summer visitor in West Pakistan (Baluchistan, Punjab and N.W.F. districts, Chitral) and in Kashmir, Ladakh, Baltistan, Himachal Pradesh, Garhwal and Kumaon; foothills and up to c. 4600 m. Winters south (c. September to March)—numbers greatly augmented by extralimital immigrants—through Sind, Rajasthan, Gujarat, Madhya Pradesh, Uttar Pradesh and Bihar; plains and hills. Possibly farther south in the Peninsula where there is a confusing intermingling of the races in winter. Affects open country, cultivation, light forest, and the neighbourhood of villages and habitations, in deciduous biotope.

Extralimital. Breeds also in Europe and Asia from S. Sweden to SW. Siberia and Kirghiz Steppe, south to NW. Africa, Palestine, Iraq, Iran, and the Altai; Mediterranean islands; occasionally England. Winters also in N. Africa and Arabia.

Tail $\times c. \frac{1}{2}$ (After Hartert)

$\times c. \frac{1}{2}$

MIGRATION. No ringing data. Continuing observations of mountaineers indicate that at least some extralimital migration occurs directly across the Himalayas. Reported frequently (subspecies?) at high altitudes, notably at c. 6400 m by the first Mount Everest Expedition in September (Wollaston, *Ibis*, 1922: 504) and on Pomori Glacier, c. 5790 m in Nepal in May (Biswas, *JBNHS* 58: 116).

Arrives in its breeding areas between early March and early April; departs August-September, a few birds wintering in the warmer lower valleys (e.g. in Kashmir and northern Baluchistan).

HOOPES

127

eggs 26.2 \times 17.6 mm (Osmaston). Incubation by female alone who is a very close sitter and fed by the male within the nest throughout the period—15 to 17 days, mostly 16 (B. S. Lamba). Both sexes feed the young. The nestlings deliberately squirt their foul-smelling liquid faeces against an intruder as a means of defence.

MUSEUM DIAGNOSIS. See Key to the Subspecies; for details of plumage, Baker, loc. cit.; for plumage phases and structure (also bionomics), Witherby, 1938, 2: 266-9.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
$\sigma\sigma$	140-153	53-63	22-24	98-109 mm
♀♀	136-148	50-58	—	—

(Witherby)

Weight 9 $\sigma\sigma$ 60-73 g (SA).

COLOURS OF BARE PARTS. Iris brown. Bill horny brown or horny black, paler (flesh colour) at gape and base of lower mandible; mouth pale flesh. Legs and feet greyish- or slaty brown.

764. *Upupa epops saturata* Lönnerberg

Upupa epops saturata Lönnerberg, 1909, *Ark. Zool.* 5, no. 9: 29
(Kjacha, southern Transbaicalia)
Baker, *FBI* Nos. 1580, Vol. 4: 310

LOCAL NAME. *Das hu dyp* (Cachari).

SIZE. Myna; length c. 31 cm (12 in.) to tip of long slender bill.

FIELD CHARACTERS. As in 763 q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident and/or breeding visitor in the Tibetan facies of the High Himalayas in Nepal, Sikkim, Bhutan and NEFA (?) above c. 1700 m; recorded up to c. 4400 m in summer and once at c. 5000 m in October. Migrates in winter to the plains in Nepal, Bihar, W. Bengal, Orissa and East Pakistan. Affects openly wooded country.

Extralimital. Eastern Siberia and Manchuria southward over Mongolia and northern China, to Yunnan, Kwangtung, and Fohkien (Peters).

GENERAL HABITS, FOOD, VOICE and CALLS. As in the European (nominate) subspecies (763).

BREEDING. Season, April to June. *Nest*, eggs and breeding biology as in 763.

MUSEUM DIAGNOSIS. Very similar to nominate *epops* (763), only a trifle darker on back and wings; also darker and more brown, less vinous, on breast. But race not very distinct and of questionable validity.

MEASUREMENTS

$\sigma\sigma$ Wing 123-164 (mostly over 140). Bill (from feathers) 59-55 mm (Baker).
15 $\sigma\sigma$ Wing 141-155 (av. 149) mm — Stresemann, *BR*.
Weight 4 $\sigma\sigma$ 59-72 g (SA, Paynter).
COLOURS OF BARE PARTS. As in 763.

126

CORACIIFORMES

GENERAL HABITS. Keeps singly or in pairs, often widely separated when feeding; in loose parties of 8 to 25 or more when freshly arrived on migration. Curious unexplained behaviour often observed at this time, of individual birds or 3s and 4s together, flying around as if demented, flitting crazily from branch to branch, crest erected and tail expanded from time to time, fluttering, twisting and turning in and out through branches and tree-trunks in slow erratic butterfly-like flight. Partial to lawns and meadows and dusty cart tracks for feeding and dust-bathing. Runs about actively with a quail-like, somewhat waddling gait, probing here and there in loose sandy soil or damp earth with bill partly open like forceps. When thus digging, crest furred to a point projecting behind, making the bird's head look like a miniature pickaxe; the crest is fanned out momentarily each time the bird settles after a short flight, and on the least excitement. Given to much territorial fighting in the breeding season: rival cocks advance at one another uneasily with crests erected and bill pointing downward, almost touching the ground. They suddenly seize each other's bill tips in a straight line as if to maintain a safe distance between themselves. Thus locked, the combatants flutter down from the branch and disengage to continue jabbing at each other on the ground until one of them retreats.

FOOD. Entirely insectivorous: largely underground grubs and pupae of beetles (Coleoptera); crickets (Gryllidae); earwigs (Forficulidae); locusts and grasshoppers (Acrididae); surface caterpillars of many species (*Agrotis*, *Opatrum*, etc.); ant-lions (*Myrmaleo*); ants and termites. Mole-crickets (*Gryllotalpa africana*) and 'bherwa' (*Schizodactylus monstrorum*) feature largely among the food items brought to the young. For details of some stomach analyses in an intensely cultivated area see Mason & Lefroy, 1912: 172-3. They point to the great usefulness of the species as a destroyer of agricultural pests.

VOICE and CALLS. Song, a deep mellow *hoo-po* or *hoo-po-po* (or *hüd-hüd-hüd*) with a peculiar ventriloquial quality; repeated again and again at about 3-second intervals—in the breeding season often for 10 or 15 minutes at a stretch. This call is very similar to that of Himalayan Cuckoo, *Cuculus saturatus* (580) and rather confusing in localities where both species occur together. However the cuckoo's is usually distinguishable by its four notes *hüd-hüd-hüd-hüd* against the hoopoe's two or three. When calling, the bird lowers and bobs its head, bill pointing downward almost flush with breast, tail depressed and turned in under the perch as if the bird were trying to make both its ends meet! At other times head jerked forward with each successive *hüd* as in a dog barking, the crest raised and lowered from time to time. A subdued harsh *ca-aw* when fighting; rasping croaks and hisses when agitated; a wheezy note by female while being fed by her mate and as a preliminary to inviting copulation by tilting forward and raising her posterior.

BREEDING. Season, late March to early June, principally April and May. *Nest*, a hollow or split in a tree-trunk, or hole in a mud or stone wall of a village house; occasionally lined scantily with grass, leaves, wool, feathers and rubbish which become fouled and matted into an evil-smelling mess with the birds' droppings as incubation proceeds. *Eggs*, 5 to 7, pale skim-milk blue when fresh soon turning to a pale dirty greenish grey and further discoloured by contact with the filthy nest lining. Average size of 26 Kashmir

(Bengal, Nepal, Nilghiris and Tenasserim). Not *Upupa indica* Latham

Upupa epops orientalis Baker, 1921, *Bull. Brit. Orn. Cl.* 42: 29. New name for *U. indica* Reichenbach, not *Upupa indica* Latham. (Ambala [Punjab] fixed as type locality by Baker, 1927, *Fauna* 4: 311, in error = Nilgiri Hills, hereby restricted)
Baker, *FBI* Nos. 1581, 1582, Vol. 4: 311, 312

LOCAL NAMES. *Hüd-hüd* (Hindi, Marathi); *Hüd-hüd* or *Ghenti tãnkô* (Gujarati); *Konda pitta*, *Kurelam pitta*, *Kukudu guwa* (Telugu); *Peruwa kurullâ* (Sinhala); *Châcal kûrûci* (Tamil); *Uppoooppân* (Malayalam).

SIZE. Myna; length c. 31 cm (12 in.) to tip of long slender bill.

FIELD CHARACTERS. As in 763. See Key to the Subspecies and Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Breeds in the Himalayas in a lower altitudinal zone than 764 (normally below c. 1500 m), in Nepal, Bihar, northern West Bengal, Sikkim and Bhutan; south through western Uttar Pradesh, central India, western Madhya Pradesh, Gujarat, Maharashtra, Andhra, Tamil Nadu, Mysore, Kerala and Ceylon. Affects open country, light deciduous forest, cultivated areas, and the neighbourhood of habitations: plains and hills to c. 1700 m.

GENERAL HABITS, FOOD, VOICE and CALLS. As in the nominate race (763), q.v.

BREEDING. Season, locally variable: chiefly April to June in northern India, January to March/April in the south, March to May and occasionally August in Ceylon. *Nest*, eggs, and breeding biology as in 763. Size of eggs (c/4-7) c. 25 \times 17 mm.

MUSEUM DIAGNOSIS. See Key to the Subspecies. Smaller, darker and more rufous than the other races. Breast with hardly any tint of vinous; rufous of head and crest deep and rich; subterminal white patches on crest feathers absent or obsolete.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
$\sigma\sigma$	120-143	51-63	20-22	83-99 mm

Upupa longirostris Jerdon, 1862, *Bds. India* 1: 393 (Burma)
Baker, *FBI* No. 1583, Vol. 4: 312

LOCAL NAME. *Songârâh*, *Songârâh* (Manipur).

SIZE. Myna; length c. 31 cm (12 in.) to tip of long slender bill.

FIELD CHARACTERS. As in 763. See Museum Diagnosis.

HORN BILLS

129

STATUS, DISTRIBUTION and HABITAT. Resident and locally migratory: Assam, Nagaland (?), Manipur and East Pakistan; plains and up to c. 1600 m. Affects grassland, open deciduous forest glades, bamboo and light scrub jungle; cultivated areas and waste land.

Extralimital. Burma, Thailand, Indochinese countries, Malay Peninsula, Sumatra (Peters).

GENERAL HABITS, FOOD, VOICE and CALLS. As in 763, q.v.

BREEDING. Season, February to May, chiefly March and April. Nest, eggs (c/5 or 6) and breeding biology as in the nominate race (763). Average size of 50 eggs 24.9 × 17.9 mm (Baker).

MUSEUM DIAGNOSIS. Paler in colour than *ceylonensis* (765) and with a proportionately longer bill on average.

MEASUREMENTS

	Wing	Bill	
♂ ♀	136-158	(from feathers) 42-66 (mostly over 50)	mm (Baker)

COLOURS OF BARE PARTS. As in 763.

Family BUCEROTIDAE: Hornbills

For description see Van Tyne, J., and Berger, A. J., 1959: 478; Stresemann, E., 1927-34, *Aves*: 832-3; Baker, E. C. S., 1927, FBI 4: 282; Bannerman, D. A., 1964, Article 'Hornbill' in Thomson, A. L. (ed.), *New Dict. Birds*, London & New York. Moults: Females renew all remiges and rectrices synchronously in the nest-hole, while the body moult is inactive. Males have a different moult pattern.

Key to the Indian Genera

	Page
A Casque large in adults, as high as, or higher than the upper mandible	
1 Casque broad, concave on top, ending anteriorly in two points	143
2 Casque compressed, ridge-like, ending in a single point	139
B Casque moderate, small or absent	
3 Casque low, broad and rounded above, composed of transverse ridges	137
4 No casque but a few oblique ridges on sides of base of upper mandible	135
5 Casque small and compressed, the upper ridges curving down in front	133
6 Casque small, compressed and pointed or wanting; no ridges on sides of bill	129

Genus *Tockus* Lesson

Tockus Lesson, 1830, *Traité d'Orn.*, livr. 4: 252. Type, by subsequent designation, *Buceros erythrorhynchus* Brisson, i.e. Temminck

Casque either absent or when present small and compressed, terminating anteriorly in a point. Bill considerably curved and carinate above. Eyelids furnished with long bristly eyelashes, as in the family. Tail long and graduated in the Indian forms.

Key to the Species

Bill with small, keel-shaped casque	<i>T. birostris</i>	130
Bill with no casque	<i>T. griseus</i>	131

HORN BILLS

131

FOOD. Largely fruit, especially wild figs (*Ficus* spp.), berries and flower petals (e.g. *Bauhinia*); also insects (beetles, mantids, grasshoppers, wasps, etc.) and lizards, mice and other small animals. Recorded eating the poisonous fruits of the Yellow Oleander (*Thevetia nerifolia*), extracting and devouring parakeet nestlings from a tree-hole, and taking fish avidly in captivity.

VOICE and CALLS. Normal note a shrill monotonous kite-like squeal *whewee*, frequently uttered. Also has a variety of loud cackling and squealing conversational notes *k-k-k-ka-ē*; while uttering these tail depressed or doubled under perch and swung slowly back and forth.

BREEDING. Season, overall March to June, the principal periods varying locally. Nest, a natural hollow in an old tree-trunk or bough c. 3 to 8 m up, sometimes enlarged to suit. After the female enters, the hollow is walled up with a mixture of wet mud collected by the male outside, and her own excreta and 'casts' by the female within, she (mostly) using her bill as trowel for the plastering. A narrow slit is left in the wall through which the male feeds his mate throughout the incubation period. After the eggs hatch and the young are about a week (?) old, the wall is broken down to release the female and then rebuilt with a narrow opening as before. Through this both parents feed the squabs till they are fully fledged. The wall is then broken down to let them out (whether by the parents, or chicks, or both?). Female evidently moults her wing-quills during her incarceration, but this needs further study. Excreta of imprisoned female and chicks ejected directly through the narrow slit with considerable force. Eggs, normally 2 or 3, rarely 4, dull glossless white, becoming stained and dirty during incubation. Average size of 30 eggs 41.9 × 30.0 mm (Baker). Incubation period undetermined.

For more detailed accounts of the nesting habits see E. F. Hall, 1918, JBNHS 25: 503-5; E. H. N. Lowther, 1942, *ibid.* 43: 389-401.

MUSEUM DIAGNOSIS. See Key to the Species; for details of plumage Baker, *loc. cit.*

MEASUREMENTS

	Wing	Bill (from posterior base of casque)	Tarsus	Tail
♂ ♀	196-228	81-105	42-46 (Baker, HW, BB, SA)	237-297 mm

COLOURS OF BARE PARTS. Iris brownish orange to red (♂), brown (♀). Bill slaty black on basal portion including casque, waxy yellow or creamy white on culmen, tips, and most of lower mandible; palate pale yellowish flesh, gullet dark slate. Legs and feet plumbeous to slaty black; claws black.

MISCELLANEOUS. Both adults and squabs widely persecuted and slaughtered for food and alleged medicinal properties. Popularly believed to cure after-childbirth pains in women. A broth prepared of the entire bird, feathers and all, is administered internally, in addition to bathing the patient with a decoction of it.

Tockus griseus (Latham): MALABAR GREY HORNBILL

Key to the Subspecies

Underparts grey; central pair of tail-feathers all or nearly all black	<i>T. g. griseus</i>
Underparts paler grey; central pair of tail-feathers with broad white tips	<i>T. g. gulgulensis</i>

130

CORACIIFORMES

767. Grey Hornbill. *Tockus birostris* (Scopoli)

Buceros birostris Scopoli, 1786, *Del. Flor. et Faun. Insulr.*, fasc. 2: 87 (Coromandel, India)

Tockus birostris pergriseus Koelz, 1939, *Proc. Biol. Soc. Wash.* 52: 79 (Lahore, Baker, FBI No. 1575, Vol. 4: 301)

Plate 59, fig. 2

LOCAL NAMES. Dhāmār, Dhānī, Dhānī, Lāmdār, Chālābrā, Dhānēh (Hindi); Selagilli (Hindi, Saugar, M.P.); Puttial dhānēh (Bengali); Rundu mukkūla guwa, Sijpānī, Kommu kasiri (Telugu); Mūmu mukkūla kākā, Irawakkē (Tamil); Chīlībrō (Gujarati); Bhīndīs (Marathi).

SIZE. Kite ±; length c. 61 cm (24 in.).

FIELD CHARACTERS. A clumsy brownish grey bird with a heavy curved blackish bill surmounted by a peculiar pointed protuberance or casque; long black-and-white-tipped graduated tail, the pattern particularly conspicuous when tail spread in alighting. Sexes alike, but casque in female smaller. Young (immature) like adult but has no casque, thus could be mistaken for *T. griseus* (768) in passing. Bill almost wholly yellow; white tips to primaries lacking.

STATUS, DISTRIBUTION and HABITAT. Resident, moving locally subject to fruiting seasons. Throughout the better wooded parts along the base of the Himalayas up to c. 1000 m (recorded at 1400 m in Kumaon [Bhim Tal]) from West Pakistan Punjab (Lahore, Sialkot) eastward through Nepal to northern W. Bengal; southward throughout the Peninsula, plains and hills, excepting the more arid parts of Rajasthan and Gujarat (Kutch), and the heavy-rainfall areas of Kerala. Absent in Assam, East Pakistan, and Ceylon. Confined to deciduous biotope. Affects open but fairly well-wooded country with a scattering of *Ficus* trees; roadside avenues, groves and rambling gardens, in the neighbourhood of cultivation and habitations.

GENERAL HABITS. Largely arboreal, but will occasionally descend to the ground and hop about with vertically cocked tail to pick fallen fruit. Similarly also for winged termites emerging from rain-sodden ground, the birds taking each insect in the bill-tip and jerking the upraised bill to transfer the morsel to the gullet; they may also spring up a few centimetres now and again to snatch the quarry in the air. Keeps in pairs or small parties of 5 or 6, feeding on fruiting trees such as banyan and peepul (*Ficus* spp.) in company with mynas, green pigeons, bulbuls and other frugivorous birds; larger assemblages — 30 or more — where food is abundant. On alarm the gathering breaks up into small parties which scatter in different directions flying in follow-my-leader style, uttering weird squeals. Flight undulating and noisy — a few rapid flaps followed by a dipping glide and sailing with the wing-tips strongly upturned. Recorded dust-bathing regularly (Hoffmann, CBCN Aug. 1980: 12).

* Biswas (JBNHS 58: 117) supports the distinctness of *T. b. pergriseus* Koelz (here synonymized). He confirms that northern Indian birds are consistently less brown and more grey than from the southern Peninsula.

CORACIIFORMES

768. *Tockus griseus griseus* (Latham)

Buceros griseus Latham, 1790, *Index Orn.* 1: 147 (New Holland = Malabar) Baker, FBI No. 1576, Vol. 4: 303

Plate 59, fig. 5

LOCAL NAMES. Kaldal hākki (Kannada); Kōchi vechāmbāl (Malayalam).

SIZE. Kite ±; length c. 59 cm (23 in.).

FIELD CHARACTERS. A plain brownish slaty grey hornbill without any casque on bill. Head, crest, throat and breast streaked with whitish. Nasal plumes and broad supercilia extending far backwards, whitish. Wing-quills black, with broad white tips to some of the primaries. Tail glossy black with broad white tips to all rectrices except the two central pairs. Sexes alike but for bill colour, q.v.

STATUS, DISTRIBUTION and HABITAT. Resident. Confined to the heavy-rainfall Western Ghats or Sahyadri strip from about Bombay and Khandala south through southern Maharashtra, Goa, western Mysore (Malnad), western Tamil Nadu (Nilgiri, Palni, and associated hills), and Kerala; from plains level to c. 1600 m. Affects rather open evergreen and moist-deciduous forest especially where abounding in *Ficus* trees; apparently the ecological counterpart here of the Grey Hornbill of deciduous country, the two species overlapping in some intermediate zones.

GENERAL HABITS. Very similar to 767, q.v. Keeps in pairs or small flocks of 6 to 20 or more, feeding in *Ficus* trees in company with other frugivorous birds and keeping up an almost incessant clamour of harsh croaks, chuckles and inane 'laughter', the flocks flying from tree to tree in follow-my-leader fashion. For a good note on behaviour of young being hand-reared see H. Abdulali, JBNHS 50: 403-4. Dipping flight in silhouette very reminiscent of Bluebearded Bee-eater or Himalayan Barbet (SA, JBNHS 72: 46).

FOOD. *Ficus* figs, drupes and berries; also insects, lizards and other small animals.

VOICE and CALLS. Shrill squeals and raucous cackling 'reminiscent the loud protestations of a domestic chicken held up by its legs' (S) 'Kyah, kyah, kyah ad lib.' (Davison).

BREEDING. Season, January to early April, chiefly February-March. Nest, eggs (c/3 or 4) and breeding biology as in 767. Average size of 50 eggs 41.8 × 30.3 mm (Baker). Foraging male on return with supply taps on side next 'window'. Offers berries regurgitated one by one and shifted to his bill-tip.

MUSEUM DIAGNOSIS. See Keys to the Species and Subspecies.

In first-year bird primaries more narrowly pointed, rectrices narrower than adult. Distinguished from adult also by paler coloration with a fulvous tinge above the vent; all wing-coverts conspicuously edged with fulvous; wing-quills edged with pale grey except the outer primaries which are conspicuously marked white.

MISCELLANEOUS. Parasitized by the ticks *Haemaphysalis spinigera* and *H. tortu* (Rajagopalan, JBNHS 69: 62).

HORN BILLS

133

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	205-220	100-110 (depth c. 40)	44-45	219-235 mm (Baker)

Wing 3 ♂ 205-218; 9 ♀ 185-195 mm (Koele, SA).

COLOURS OF BARE PARTS. Adult male: Iris red-brown; orbital skin black. Bill horny yellow with a brownish red tinge on all but tip. Legs and feet greenish slate to greyish sage-green; claws black. Adult female: Bill waxy yellow with irregular brownish slate patches along culmen and at base of lower mandible. Rest as in ♂. Immature: Iris grey to brown. Bill pale yellow; commissure, gape, a patch on either side of lower mandible, and a triangular patch on culmen (near forehead) brownish slate colour.

769. *Tockus griseus gingalensis* (Shaw)

Buceros gingalensis Shaw, 1811, Gen. Zool. 8(1): 37 (Ceylon)
Baker, FBI No. 1577, Vol. 4: 304

LOCAL NAMES. *Kanditā* (Sinhala); *Irattai chondu kūrūri* (Tamil).

SIZE. Kite —; length c. 59 cm (23 in.).

FIELD CHARACTERS. As in 768. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident; Ceylon. Fairly common throughout the forests of the low country; seasonally (September–October) in the hills to c. 1200 m.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 768, q.v. 'A loud *kāā* . . . *kāā* . . . *kāā* *kāā* . . . or sometimes *kuk* . . . *kuk-kuk-kuk ko ko kokoko* which is answered by its mate in similar tones' (Henry).

BREEDING. Season, April–May, occasionally in July. Nest, eggs, and breeding biology as in 768.

MUSEUM DIAGNOSIS. Differs from the Malabar population (768) in being much paler grey below and with much more white on the outer tail-feathers, the three outer pairs becoming pure white in old birds.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂ ♂	192-215	101-110	38-41	210-226 mm
♀ ♀	191-202	82-89	37-41	186-213 mm (HW, SDR)

Weight 1 ♂ 238 g (SDR).

COLOURS OF BARE PARTS. Iris: ♂ red; ♀ brown. Bill: ♂ horny white with a black patch at base of upper mandible, and another indistinct patch beneath lower mandible; ♀ horny black with a long sharply defined white patch on lower portion of upper mandible. Legs and feet greenish plumbeous.

Genus *PTILOLAEMUS* Ogilvie-Grant

Ptilolaemus Ogilvie-Grant, 1892, Cat. Bds. Brit. Mus. 17: 349 (in key), 392. Type, by subsequent designation, *Buceros tickelli* Blyth. (Richmond, 1902, Proc. U.S. Nat. Mus. 24: 711)

Throat well feathered. Casque small, compressed and sharp-edged. Feathers of head normal, lengthened posteriorly and forming a full crest. Sexually dimorphic.

HORN BILLS

135

during incubation. Average size of 24 eggs 48.8 × 34.2 mm (Baker). Period of incubation undetermined; reported by local Nagas as 24 days.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	312-337	121-135	c. 50	281-297 mm (Baker)

COLOURS OF BARE PARTS. Iris dull brown. Bill and casque dull wax-yellow, reddish yellow on sides near base; orbital skin bluish white or bright blue ('pale yellow' [?] — Baker). Legs dull horny green, dirty yellow at sides; claws dusky black.

Genus *ACEROS* J. E. Gray

Aceros J. E. Gray, 1844, Zool. Misc.: 85. Type, by monotypy, *Aceros nipalensis* = *Buceros nipalensis* Hodgson

Distinguished by absence of a true casque though basal portion of culmen thickened and sometimes showing an incipient protuberance. Sides of upper mandible near base grooved or ridged in adult. Cheeks, chin and throat naked. Tail long and graduated. Feathers of head long, loose and hair-like forming a bushy crest. Sexually dimorphic

771. *Rufousnecked Hornbill. Aceros nipalensis* (Hodgson)

Buceros nipalensis Hodgson, 1829, Asiat. Res. 18 (1): 178, 2 pls. (Nepal)
Baker, FBI No. 1570, Vol. 4: 294
Plate 59, fig. 9

LOCAL NAMES. *Deo yung gajao* (Cachari); *Kolep* (Lepcha).

SIZE. Vulture; length c. 122 cm (48 in.).

FIELD CHARACTERS. Male. Head (with bushy mop-like crest), neck, and breast rufous, changing to maroon on abdomen and blackish maroon farther down. Rest of upper plumage black, glossed with dark green. Outer primaries tipped white. Terminal half of long graduated tail white. Heavy horn-shaped yellow bill without casque; vertically ridged with blackish on sides of upper mandible. Cheeks, chin, and throat naked, bright scarlet; naked patch round eye blue.

Female all black, but with outer primaries white-tipped as in male, and terminal half of tail also white.

Young (immature) like adult, sex for sex, but with much smaller bill, and without the lateral ridges.

STATUS, DISTRIBUTION AND HABITAT. Himalayan foothills to c. 1800 m elevation, Nepal eastward through Sikkim, Bhutan and NEFA. North-eastern Assam (Cachar), Nagaland, Manipur, Mizo Hills, East Pakistan

× c. 1/2

CORACIIFORMES

134

770. *Whitethroated Brown Hornbill. Ptilolaemus tickelli austeni* (Jerdon)

Anorhinus [sic] *austeni* Jerdon, 1872, Ibis: 6 (Asalu, Cachar Hills)
Baker, FBI No. 1573, Vol. 4: 298
Plate 59, fig. 3

LOCAL NAME. *Deo yung lai* (Cachari).

SIZE. Kite +; length ♂ c. 76 cm (30 in.), ♀ smaller.

FIELD CHARACTERS. A medium-sized hornbill chiefly dark brown above, bright rufous below, with a small sharp-edged yellowish casque on the culmen. Cheeks, throat and sides of neck white; foreneck pale rufous. Tail long, graduated, black and broadly tipped with white excepting the middle pair of rectrices which are all brown and without white tips.

Female has sides of neck concolorous with crown. Below more grey-brown, less rufous, with no rufous on foreneck or upper breast. Colour of bill as in male.

× c. 1/2

STATUS, DISTRIBUTION AND HABITAT. Not uncommon where occurring, but distribution imperfectly known. Assam hills south of the Brahmaputra and Luhit rivers, Nagaland (?), Manipur (?); plains, foothills and to c. 1000 m alt. Affects evergreen forest.

GENERAL HABITS. Keeps in noisy cackling flocks of 8 to 10 birds — often up to 20 or more — to the tops of lofty forest trees, feeding in company with Pied Hornbills and other frugivorous birds. Very restless, constantly moving about in the branches or flying from tree to tree in follow-my-leader style, the birds launching one by one and maintaining their individual distance in the air. Flight, as of the family — a few rapid wing-beats followed by sailing with the wing-tips upcurved, again a few flaps, and so on — but comparatively noiseless.

FOOD. Wild figs, drupes, and berries; also insects, and doubtless lizards and other small animals.

VOICE AND CALLS. Loud croaks, chuckles and squeals similar to those of the Pied Hornbills (774, 775), but somewhat less harsh.

BREEDING. Season, chiefly April to June. Nest, a hollow in a tree at comparatively low heights (4 to 8 or 9 m), sometimes higher. Partially walled up with the bird's excrement and pulp of fruits etc. as usual, with the incubating female within who is fed by the male through the narrow opening throughout her incarceration. Eggs, 3 or 4, white, but becoming stained and dirty

¹ The illustration is of a male of the closely similar nominate race (with all tail-feathers white-tipped) only known from Tenasserim, Lower Burma.

CORACIIFORMES

136

(Chittagong Hill Tracts). Affects tall evergreen forest; not uncommon patchily, but reportedly disappearing from many areas consequent on steady felling of primeval forest.

EXTRALIMITAL. Hills of Burma south to Tenasserim, northern Thailand and Indochinese countries.

GENERAL HABITS. Chiefly arboreal and frugivorous. Occasionally descends to the ground to pick fallen fruit, moving in ungainly shuffling hops. Keeps in pairs or small parties of four or five to tall forest on hillsides, sailing majestically across deep wooded valleys — 3 or 4 rapid, noisy 'full' wing-flaps followed by a glide on flat outstretched pinions for 3 or 4 seconds, and so on. Has a curious habit of diving with closed wings for some distance from time to time to make long swooping dips in its flight like a woodpecker. The male has a bizarre nuptial display accompanied by loud discordant roars and cackles. Perched on a bough 'head thrown back, red hair on end, his gular skin inflated and his bill held erect and wide open. His wings hang loosely and slightly quivering, whilst every now and then his long tail is jerked up until it almost touches the head' he shows off thus to his mate (Baker).

FOOD. Large drupes and berries swallowed entire; the fruits of *Dysoxylon* sp. and nutmegs (*Myristica*) are especially favoured; in one case 18 large nutmegs in stomach, complete with mace, weighing 98 g (SA).

VOICE AND CALLS. A variety of loud roars, croaks and cackles. Male has a short 'bark' reminiscent of the distant stroke of an axe upon a sapling; female's bark slightly different in tone. Frequently uttered by a pair in irregular duets, then easily mistakable in the distance for two woodcutters chopping alternately and sometimes striking almost together.

BREEDING. Season, chiefly April and May. Nest, a natural hollow in a lofty tree-trunk in forest, between 10 and 30 m up; walled up by the female from within with her own excreta and viscid pulp of figs and other fruit remains; possibly supplemented with mud by the male from outside (as in 767). She leaves a narrow slit or window through which she is fed by her mate throughout the incubation period. The same hollow is used year after year. Eggs, 1 or 2, white, with a coarse texture. Average size of 12 eggs 59.2 × 43.1 mm (Baker). Incubation period undetermined.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail

(SA)

HORNBILLS

137

COLOURS OF BARE PARTS. Iris deep reddish orange (♂), claret (♀); orbital skin brilliant sky blue. Bill yellowish ivory; lateral ridges on upper mandible (up to 8) black. Gular skin (pouch) brilliant orange-scarlet criss-crossed with fine brown creasing; fleshy pads at sides of base of lower mandible deep purplish violet connected by a narrow band across the orange gular skin. These colours differ slightly in details in the sexes and/or ages. Legs, feet and claws black.

Genus RHYTICEROS Reichenbach

Rhyticeros Reichenbach (1849), Av. Syst. Nat. pl. L. No species; generic details only. Species added, Bonaparte, 1854, Ateneo Italiano 2: 312. Type, by subsequent designation, *Buceros plicatus* Latham, i.e. Forster

Casque small, rounded and corrugated in appearance, composed of plates the upper edges of which form alternate ridges and furrows. Chin and throat naked forming a pouch capable of great inflation. Feathers of crown long and loose forming a shaggy crest. Sexually dimorphic.

772. Assam Wreathed Hornbill. *Rhyticeros undulatus ticehursti* Deignan

Rhyticeros undulatus ticehursti Deignan, 1941, Auk 58: 397 (Hua Oi, 14 km north of the Ban Pak Li, Nan Province, Thailand)
Baker, FBI No. 1567 (part), Vol. 4: 291

Plate 59, fig. 7

LOCAL NAMES. *Mah do la* (Assamese); *Dao rai* (Cachari).

SIZE. Vulture ±. Overall length ♂ c. 114 cm (45 in.); female, with shorter bill, c. 98 cm (38 in.).

× c. 1

FIELD CHARACTERS. A large black hornbill with entirely white tail.

Male. Forehead, crown, and nape deep chestnut passing into black on hindneck. Sides of head and neck, and foreneck, buffy white. Tail all white; rest of plumage glossy black. Bill pale yellow; naked throat-patch bright yellow.

Female. All black except tail which is wholly white.

In high overhead flight jet black body and underwing, white neck, dark crown, and all-white tail are diagnostic of the male. On a nearer view the very bright yellow throat-pouch, puffed and sticking out like a goitre, is

773. Narcondam Hornbill. *Rhyticeros (plicatus) narcondami* (Hume)

Rhyticeros narcondami Hume, 1873, Stray Feathers 1: 411 (Narcondam Island)
Baker, FBI No. 1569, Vol. 4: 293

Plate 59, fig. 1

LOCAL NAMES. Unrecorded.

SIZE. Kite +; length ♂ c. 66 cm (26 in.), ♀ somewhat smaller.

FIELD CHARACTERS. A medium-sized black hornbill with white tail.

Male. Head and neck rufous; throat a little paler. Tail white; rest of plumage black, glossed with dark green.

Female. All black excepting tail which is white as in male.

STATUS, DISTRIBUTION AND HABITAT. Endemic; resident. Narcondam Island (Andamans). Was common and fairly plentiful 50 years ago. In 1905 total 'world' population estimated by B. B. Osmaston at about 200 individuals, all confined to an area of less than 3 square miles (JBNHS 16: 620-1). Reported in April 1969 to be still plentiful on the island (B. R. Grubb). Estimated population 400 birds (Hussain). Affects high forest covering the lower slopes of the central peak (c. 700 m) down to the coast.

GENERAL HABITS AND FOOD. Osmaston and Grubb both found them noisy and fearless, feeding exclusively on wild figs. Among other fruit items identified, *Anamirta cocculus* and *Bassia latifolia*. Flight heavy and slow (Hume).

VOICE AND CALLS. 'Loud ka-ka-ka-ka with tone quality of domestic fowl's cackle. Often 3 or 4 birds sitting in a single tree calling' (Grubb).

BREEDING. Season commences February; in full swing March/April. Nest-holes chiefly high up in tree-trunks of *Tetrameles nudiflora*, *Salmalia insignis*, *Parishia insignis* etc.; many as low as 2 metres and exposed. Eggs 2, earthy brown in colour. Size c. 33 × 45 mm weighing c. 28 g (S. A. Hussain).

MUSEUM DIAGNOSIS. Bill apparently varies considerably with age in regard to the furrows as well as its total length; proportionately to the depth it is shorter in female than in male.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂♂	303-305	121-126	46-50	195-198 mm
♀♀	285-287	—	—	180-182
		(from feathers)		(Baker)
		(from skull)		
4 ♂♂	305-322	119-123	41-44	187-205 mm
3 ♀♀	295 (3)	100-109	39-42	c. 180-189 mm
Weight 4 ♂♂ 700-750 g; 3 ♀♀ 600-750 g.				
			(Grubb)	

COLOURS OF BARE PARTS. Iris: ♂ brilliant orange-red with a fine circle of pale yellow next the pupil; ♀ dark olive-brown with the same thin circle of pale yellow. Orbital skin rich smalt blue; gular skin same colour, in places lighter almost white. Bill waxy yellow: furrows of casque light brown, of a pinkish shade near base. Legs and feet black; soles yellow (C. P. Cory, JBNHS 14: 372, and coloured plate).

Genus ANTHRACOCEROS Reichenbach

Anthraceros Reichenbach (1849), Av. Syst. Nat., pl. xlix. No species; generic details only. Type, by subsequent designation, *Buceros malabaricus* Gmelin

138

CORACIIFORMES

distinctive. All-black body contrasting with all-white tail makes the female unmistakable.

STATUS, DISTRIBUTION AND HABITAT. Bengal duars, Bhutan foothills, NEFA, Assam, Nagaland, Manipur, Mizo, and East Pakistan. From plains level to c. 2400 m. Affects forest and edges of clearings in tropical evergreen biotope. Not uncommon, but usually very shy due to persecution by locals almost everywhere for its flesh and feathers.

Extralimital. Burma, Thailand, Indochinese countries and Malay Peninsula north of the Isthmus of Kra; Mergui Archipelago.

GENERAL HABITS. Mainly arboreal and frugivorous. Keeps in pairs and small parties, gathering in some numbers where food is plentiful. Has a particularly noisy flight, 'a rhythmic beat sounding like the puffing pant of a steam locomotive' (SDR) audible at great distances. Flight—a few full wing-flaps followed by sailing and punctuated with occasional 'whooshing' dives with closed wings to lose height, resulting in undulations as in a woodpecker. Flight noted as noiseless in damp rainy weather (Stevens). Like other large hornbills has a very punctual time schedule of daily feeding circuits and roosting flights. Large numbers congregate at sunset, flying high in irregular follow-my-leader style over fixed routes for roosting in selected patches of giant bamboo or tall thinly foliated trees.

FOOD. Large drupes, wild figs and berries; also lizards and other small animals. The morsel is jerked up in the air from the bill-tip, caught in the open gullet and swallowed entire.

VOICE AND CALLS. Perhaps less noisy than most other large hornbills. Male utters a short raucous grunt from a perch, his tail drooping, bill jerked skywards to the vertical at each call and then lowered again. This repeated from six to a dozen times in succession—a ludicrously mechanical performance.

BREEDING. Season, chiefly April and May. Nest, a natural hollow in a lofty tree-trunk usually at a great height—25 or 30 m. Breeding biology similar to that of other large hornbills, e.g. Great-Pied (776) q.v. Eggs, 2, white, coarse textured. Average size of 25 eggs 63 × 43.2 mm (Baker). Incubation period unknown.

MUSEUM DIAGNOSIS

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂♀	458-505	(from feathers) 202-219 (♂) 178-198 (♀)	60-70	300-330 mm

(Baker)

COLOURS OF BARE PARTS. Male. Iris orange-red to blood-red; orbital skin dull red to brick-red. Bill wax-yellow, tinged with dull orange at base; corrugations at base of both mandibles dark reddish in the furrows; casque dull yellow with dark reddish furrows. Gular skin bright yellow to orange-yellow with a broad transverse black band, generally interrupted in the middle. Legs and feet greenish- to blackish slate. Female. Iris brown or grey-brown. Bill yellow without reddish tinge. Gular skin bright dark blue with transverse black band as in male.

CORACIIFORMES

140

Hydrocissa Bonaparte, 1850, Consp. Av. 1: 90. Type, by subsequent designation, *Buceros monoceros* Shaw = *Buceros coronatus* Boddaert

Casque very high and large, sharp-edged and projecting in front, broader and carried back above crown behind, the upper outline curved parallel with commissure. Orbital skin and a patch on either side of throat bare; chin and middle of throat feathered. Tail long and graduated. Wings short and rounded. The sexes differ only in the coloration and size of bill, and shape of casque.

Key to the Species

(India = Chandernagor, *apud* Baker)

Baker, FBI No. 1565, Vol. 4: 288

Plate 59, fig. 6

LOCAL NAMES. *Hay tuk tek* etc, *Káo dhánéh* (Assam); *Dao yang kashiba* (Cachari).

SIZE. Vulture —; length ♂ c. 89 cm (35 in.), ♀ somewhat smaller.

FIELD CHARACTERS. A large black and white (or pied) hornbill with black neck, white underparts and ponderous wax-yellow and black bill surmounted by a high ridge-like casque ending in front in a single point. Outer tail-feathers black, only white at the ends. See Key to the Species.

Female similar but smaller, with a different colour pattern on bill.

STATUS, DISTRIBUTION AND HABITAT. Resident subject to local movements dependent chiefly on food supply (fruiting seasons). From about Kalesar, Punjab (Waite, JBNHS 39: 862), and Dehra Dun and the Siwalik range in Kumaon ('occasional winter visitor to New Delhi'—Frome, JBNHS 47: 288) eastwards through U.P., Nepal and Sikkim terai, Bengal duars, Bhutan and NEFA foothills; Assam north and south of the Brahmaputra, Nagaland, Manipur, Mizo Hills (?), East Pakistan; Bihar, Orissa, eastern Andhra and eastern Madhya Pradesh (Bastar dist.). Apparently overlapping with *coronatus* in eastern Chota Nagpur (South Bihar) and adjacent hilly forests of Orissa and W. Bengal, but no hybrids known. Affects open forest in moist-deciduous and evergreen biotope, also groves of large mango and suchlike trees around habitations; from plains level to c. 350 m.

Extralimital. Extreme northern Burma. The rest of Burma south to Tenasserim and northern Malay Peninsula together with Thailand, the

♂, × c. 1

HORNBILLS

141

Indochinese countries and SE. China are inhabited by the slightly smaller equivocal subspecies *leucogaster*.

GENERAL HABITS. Arboreal and mainly frugivorous. Keeps in noisy parties of 4 or 5 or small flocks of 8 to 10; larger congregations on fruit-laden trees (*Ficus* etc.) in company with Grey hornbills, green pigeons and other fruit-eaters. Flight less noisy than of the larger hornbills — a few quick flaps alternated with sailing, wing-tips upcurved and tail expanded, the birds moving from tree to tree in follow-my-leader style. Feeds a good deal on the ground, individuals and small parties not uncommonly seen hopping about to pick fallen fruit or seize creeping prey; food picked up in bill-tip, jerked into the air, caught in gullet and swallowed. Very fond of dust-bathing (Primrose, JBNHS 27: 950). Also takes termites from termite mounds, deftly picking up the tiny insects one by one in the point of the enormous bill; flying termites occasionally hawked in mid-air by ludicrously ungainly sorties. Becomes exceedingly tame and makes an amusing pet when hand-reared from nestling, flying about loose and coming to be fed; but is a tyrant in the aviary and will kill and devour any small bird.

FOOD. Wild figs, drupes and berries (*Ficus*, *Melanoxylon*, etc.). 'Passionately fond of live fishes which it catches in shallow pools. Fish bones found in stomachs of several shot' (Inglis in Hume, SF 5: 20-21). Also marauds nestling birds from tree-holes, and takes lizards, snakes, and any other small animal that can be come by.

VOICE AND CALLS. A variety of loud shrill squeals and raucous cackles. Described as 'inane screams between the protestations of a dak bungalow chicken seized by the cook and the squeals of a three-quarters grown pup receiving punishment' (SA). A 'rapid, piercing kak-kak, kak-kak' (R. L. Fleming).

BREEDING. Season, principally April and May. Nest and breeding biology as in 767 and 776, qq.v. Eggs, 2 or 3, white, smaller replicas of those of the Great Pied Hornbill (776), with a somewhat smoother texture. Average size of 18 eggs 49.9 × 34.9 mm (Baker). Period of incubation undetermined.

MUSEUM DIAGNOSIS. See Key to the Species.

Juvenile. 'A dull edition of the adult with but little gloss on the black parts of the plumage. Area round eyes and sides of chin bare as in adults. Casque smaller and of different shape. Tail-feathers narrower. Black marks on casque not so extensive' (Ticehurst, JBNHS 36: 935 — for *A. m. leucogaster*). No indication of casque when 2 months old; casque estimated to mature at 7 to 9 months of age (E. P. Gee, ibid. 36: 751), but the point needs elucidation.

MEASUREMENTS

	Wing	Bill (from forehead)	Tarsus	Tail
♂♂	294-315 (once 336)	159-170	60-68	259-318 mm
♀♀	280-301	136-146	c. 60	259-290 mm (Baker, SA, SDR)

COLOURS OF BARE PARTS. Male. Iris red-brown to blood-red; orbital skin bluish white to pale purplish blue; naked throat-patch duller, more fleshy blue. Bill and casque wax-yellow, a black patch running from the fore part of the casque to the centre of the join between the casque and the upper mandible; extreme bases

HORNBILLS

143

blue-brown; orbital skin, cheek-pads and gular skin pinkish creamy white. Bill creamy white: terminal two-thirds of casque, and patch at base of lower mandible, black (SA). Bill with the black less in extent, and absent on the back of the casque. Rest as in the male.

Genus *BUCEROS* Linnaeus

Buceros Linnaeus, 1758, Syst. Nat., ed. 10, 1: 104. Type, by subsequent designation, *Buceros rhinoceros* Linnaeus

Size large. Bill very large, stout, and much curved; casque large and broad, covering more than basal half of culmen, the sides flat and vertical behind, the top overhanging in front. Posterior edge of casque broad and rounded, projecting over the head behind; its upper surface flat or slightly convex posteriorly, concave in front terminating in two lateral points, blunted in old males. Feathers of neck and nape loose and long, but not forming a real crest. Chin feathered; small orbital patch naked. Tail long and rounded. Sexes alike in plumage.

776. Great Pied Hornbill. *Buceros bicornis homrai* Hodgson

Buceros homrai Hodgson, 1832, Jour. Asiat. Soc. Bengal 1: 251 (Nepal)

Baker, FBI No. 1563, Vol. 4: 284

Plate 59, fig. 44

LOCAL NAMES. *Homrai* (Nepal); *Bāmrao* (Hindi, Kumaon); *Kugrong*, *Kudong* (Lepcha); *Gāridā* (Kannada); *Gārid* (Marathi); *Malāmōrīkki* (= 'mountain-shaking'), *Vīzhāmbāl*, *Kōmban rēzhāmbāl* (Malayalam); *Rāj dhānzih* (Bengal); *Rāj dhānzih*, *Hivāng* (Assam); *Dao jung* (Cachari); *Inrai* go (Kacha Naga).

SIZE. Vulture; length ♂ to tip of bill c. 130 cm (52 in.), ♀ somewhat smaller.

FIELD CHARACTERS. A large black-and-white hornbill with enormous horn-shaped yellow-and-black bill surmounted by a ponderous concave-topped casque, broadly U-shaped when viewed from the front. Face, back,

♂, × c. 1/2,

underparts and wings black, the last with double white bars. Neck, lower abdomen, upper and under tail-coverts and tail white, the last with a broad black subterminal band.

The white neck and wing-bars, and black band in the white tail, are diagnostic in flight.

Female similar, but slightly smaller and with smaller bill and casque (see colours of bare parts).

CORACIIFORMES

142

of casque and bill, and commissure, black. Legs and feet dull dark slate or greenish slate. Female. Iris brown or grey-brown. Whole fore part of casque, top and upper part of upper mandible, and commissure, black; bold black streaks on lower mandible, the amount of black variable but always more extensive than in male.

775. Lesser Pied Hornbill. *Anthracoceros coronatus coronatus* (Boddaert)

Buceros Coronatus Boddaert, Table Pl. enlum.: 53 (Malabar)

Baker, FBI No. 1564, Vol. 4: 286

Plate 59, fig. 8

LOCAL NAMES. *Dhān chiri* (Hindi); *Sulimani mānghi* (Deccani); *Dhānzih* (U.P.); *Bagma dhānzih* (Bengal); *Kūchā khā* (Orissa); *Wagerā* (Marathi); *Kanari* (Konkan); *Peshā gonda* (Gond); *Poruvā kōndetta* (Sinhala); *Iretti chōnda kūrūri* (Tamil); *Vīzhāmbāl* (Malayalam).

SIZE. Vulture —; length ♂ c. 92 cm (36 in.), ♀ somewhat smaller.

FIELD CHARACTERS. A large black and white (or pied) hornbill with black neck, white underparts and ponderous wax-yellow and black bill surmounted by a high ridge-like casque ending in front in a single point. Very similar to 774 but with the outer tail-feathers all white. See Key to the Species.

Female similar but smaller, and with the bare parts somewhat differently coloured.

STATUS, DISTRIBUTION AND HABITAT. Resident; subject to local movements governed by food supply (fruiting seasons). Extreme western part of W. Bengal bordering Chota Nagpur and Orissa (where it partly overlaps the range of *A. malabaricus*), Andhra and Madhya Pradesh. The western side of the Peninsula, chiefly the wooded country inland along the foot of the Ghats, from about Ratnagiri (south of Bombay) through Goa, W. Mysore (Malnaad) and W. Tamil Nadu (Nilgiri dist.) and Kerala. Ceylon ('very local but fairly plentifully distributed in the more secluded forest areas of the Dry zone' — Phillips). Affects open forest in evergreen and moist-deciduous biotope; plains and foothills to c. 300 m. Also groves of large mango, *Ficus* and suchlike trees around forest villages.

GENERAL HABITS, FOOD, VOICE AND CALLS. Almost identical with 774, q.v.

BREEDING. Season, in the Peninsula chiefly March and April; in Ceylon April to July. Nest, breeding biology, and eggs as in 774. Clutch size and incubation period undetermined. Size of eggs c. 55 × 38 mm.

MUSEUM DIAGNOSIS. See Key to the Species.

MEASUREMENTS

	Wing	Bill (from forehead)	Tarsus	Tail
♂♂	315-342	216-227 (from gape)	c. 65	295-335 mm
♀♀	295-328	126-166	c. 61	— (Baker, SA)

Weight 1 ♀ 1000 g (SA).

COLOURS OF BARE PARTS. Male. Iris orange-red to red; orbital skin black or blue-black. Bill wax-yellow, black at base of true bill and of casque; also on terminal half or two-thirds of the latter. Bare throat-patch flesh coloured (yellowish pink). Legs and feet slaty grey, greenish grey or dark grey. Female. Iris brown or

CORACIIFORMES

144

Young in early stage without casque, but rudiments of it appear when about six months old.

STATUS, DISTRIBUTION AND HABITAT. Resident; subject to local movements governed by food supply (fruiting seasons). The Sahyadri or Western Ghats complex from about Khandala (18°N, 74°E.) in Maharashtra south through Goa, western Mysore (Malnaad), western Tamil Nadu (Nilgiri and associated hills), and Kerala; curiously enough absent in Ceylon. A disjunct population in the lower Himalayas from Kumaon eastward through Nepal, Sikkim, Bhutan, NEFA, Assam, Nagaland, Manipur, Mizo and East Pakistan (Chittagong Hill Tracts). Affects evergreen and moist-deciduous forest, from plains level to c. 1500 m in the Ghats and Assam hills; to c. 2000 m in the Himalayas.

Buceros bicornis

■ Distributional range

Extralimital. Burma, Thailand, Malay Peninsula, Indochinese countries and Sumatra.

GENERAL HABITS. Largely arboreal and frugivorous; occasionally descending to the ground and hopping about to pick up fallen fruits. Keeps in pairs or small parties of 3 to 5; gatherings of 30 or more at lavishly fruiting banyan or peepul (*Ficus*) and suchlike trees, and also at roosting sites. Once a congregation of '150 to 200 birds' in SE. Bhutan lowlands (G. F. Hamilton, personal communication). Moves along boughs by quick ungainly but buoyant sideways hops, bouncing lightly to a higher or lower perch from one branch to another. Covers enormous feeding circuits in the course of the day and is remarkably punctual in its visits to the various trees; also in its roosting habits, the birds usually following the same routes day after day as to a fixed time-table. Flight laboured and very noisy — 3 or 4 deliberate flaps punctuated by spells of sailing on outspread wings with upcurved tips, and

London (1): 121 ('On the Gangas between Calcutta and Benares, and the Vindhyan Hills between the latter place and Gurrah Mundela on the Nerbudda') **Therapsid zeylanica kungia** Whistler & Kinnear, 1934, Jour. Bombay nat. Hist. Soc. 37: 516 (Ranial, 2000 ft., Kangra)

LOCAL NAMES. *Bada baidia* (Hindi and Bengali); *Jokar pahit* (Bengal); *Kishna* (Deccan); *Kishna*, *Gumma* (M.P.); *Kolar* (U.P.); *Sunier* (Bihar); *Kishna* (Madras). **SIZE.** Mylna +; length c. 27 cm (10½ in.).

FIELD CHARACTERS. A dumpy stout-billed grass-green arboreal bird. Head, neck, upper back and upper breast brown, streaked with whitish; lower breast and abdomen pale green. Under surface of tail bluish. A conspicuous naked orange-coloured patch around eye extending to base of bill. Sexes alike. **Persistent** *kithoo* calls and noisy dipping flight distinctive. Young (immature) similar to adult but obscurely streaked and overall much paler and duller.

STATUS, DISTRIBUTION AND HABITAT. Resident. The lower western Himalayas (up to c. 800 m) from Kangra in Himachal Pradesh to Kumaon Mr Abu and Gujarat, east through Madhya Pradesh and northern Maharashtra to Bihar, W. Bengal (straggling as far as Calcutta), and Orissa south to Godavari R. The races intergrade into one another and borderline cases are difficult to place. Affords well-wooded moist and dry deciduous country, often frequenting roadside avenues and entering gardens within city limits.

152

and on culmen (non-breeding), reddish orange (breeding); mouth pale pink. Legs and feet lemon-yellow; claws dusky.

781. *Megalaima zeylanica inornata* Walden **LOCAL NAMES.** *Kitha* (Mahrishi); *Kitha kathi* (Kannada); *Caru kama* (Telugu). **SIZE.** Mylna +; length c. 27 cm (10½ in.). **FIELD CHARACTERS.** As of 780. See Key to the Subspecies and Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident. Western India from about the Godavari river in Maharashtra south through Goa and Mysore to Coorg district. Habitat as in 780. **GENERAL HABITS, FOOD, VOICE AND CALLS.** As in *cantilepis* (780), q.v. A minor pest of coffee plantations in Mysore, avidly devouring the ripe 'cherries', often involving appreciable loss to the growers. **BREEDING.** Season, chiefly March, April and May. Nest and eggs (c. 2-4) as in the other races. Average size of 18 eggs 30.5 x 21.8 mm (Baker). **MUSEUM DIAGNOSIS.** Differs from the Kerala and Ceylon populations (782) in having the brown extending further on to the breast and back. General plumage paler and duller with the streaks on the breast narrower and confined to the pale bar. Pale specks on wing-coverts wanting; streaks on head and upper back less conspicuous. **MEASUREMENTS** and **COLOURS OF BARE PARTS.** As in *M. z. cantilepis* (780). **Weight:** ♂ 123 g (S.A.).

782. *Megalaima zeylanica zeylanica* (Cmelin) **Bucco zeylanica** Cmelin, 1788, Syst. Nat. 1 (1): 408 (Ceylon) **LOCAL NAMES.** *Kitha kathi* (Kannada); *Caru kama* (Telugu); *Kishna* (Malayalam); *Pollu kishna*, *Chibbi kishna* (Sinhala); *Kitha*, *Kishna* (Tamil). **SIZE.** Mylna +; length c. 27 cm (10½ in.). **FIELD CHARACTERS.** As of 780, q.v. See Museum Diagnosis. **STATUS, DISTRIBUTION AND HABITAT.** Resident. Kerala and southern Tamil Nadu, mostly in the moist-deciduous low country and foothills, sometimes up to c. 1200 m. Ceylon — widely distributed and plentiful throughout the lowlands and lower hills to c. 1500 m. Habitat as in the other races.

149

BARBETS

COLOURS OF BARE PARTS. Its dark brown or reddish brown. Bill yellow on proximal half, black on distal half of culmen and distal quarter of sides of upper mandible (tip white in many examples), yellowish grey on middle part of culmen, pale greenish yellow elsewhere. Legs and feet greenish slaty; claws horny black with greenish slaty bases; pads white (Biswas).

778. *Megalaima virens magnifica* Baker

LOCAL NAME. *Dakunt lama* (Cachar). **SIZE.** Mylna +; length c. 33 cm (13 in.). **FIELD CHARACTERS.** As of 777. See Museum Diagnosis. **STATUS, DISTRIBUTION AND HABITAT.** The Himalayas east of western Nepal — Sikkim, Bhutan, NEFA. Also Cachar, Nagaland, Manipur, and East Pakistan in the Chittagong Hill Tracts; from c. 1000 to 3000 m. Affords subtropical evergreen and moist temperate forest.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 777, q.v. **BREEDING.** Season, chiefly April and May. Nest and eggs as in 777. Full clutch said by Baker to be of 2 or 3 eggs, never 4. Average size of 30 eggs 34.9 x 24.3 mm (Baker). **MUSEUM DIAGNOSIS.** Similar to *M. v. marshallorum* (777) but much more deeply and richly coloured both above and below.

MEASUREMENTS		Wing		Bill		Tarsus		Tail	
♂	♀	♂	♀	♂	♀	♂	♀	♂	♀

WEIGHTS 3 ♂ 250-295 g; 3 ♀ 192-206 g (S.A.). **COLOURS OF BARE PARTS.** As in 777. Noted also as: Its brownish crimson. Bill yellow at base, slightly greenish anteriorly; a broad horny black band, c. 5 mm wide, along ridge on terminal three-fourths of culmen. Legs and feet olive-plumbeous; claws horny black (S.A.).

779. *Megalaima virens mayi* Ripley

LOCAL NAMES. None recorded. **SIZE.** Mylna +; length c. 33 cm (13 in.). **FIELD CHARACTERS.** As of 777. See Museum Diagnosis.

151

BARBETS

Has become conspicuously common and abundant in New Delhi during the last forty years due to increases in wooded gardens and roadside avenues with large *Ficus* and other fruit-bearing trees in the process of the city's development as India's metropolis. But is not a new arrival in the area as often believed, being described as 'common' in the (Old) Delhi environs even in 1893 (J. Moray Brown in *Singapore Sport*).

GENERAL HABITS. Arboreal and eminently frugivorous. Usually keeps singly or in small loose feeding parties, but gatherings of 20 and more frequently collect on a large fruit-laden banyan or peepul tree in company with mynas, bulbuls, green pigeons and other frugivorous species. Rather silent in winter, but waxes extremely noisy with the hot weather, the jungle then resounding with its monotonous but characteristic calls throughout the day. As soon as one bird begins calling it is promptly and unfailingly joined by a second, followed maybe by a third and a fourth and more within a ceshor, to sustain the uneven chorus *ad nauseum*. The sudden report of a gun will often start off several birds calling at once. The typical barbet flight is noisy and dipping, a few rapid wing-beats followed by a short downward glide.

FOOD. *Ficus* figs, and a large variety of drupes and berries; flower petals, e.g. *Bauhinia*, and flower nectar (*Erythrina*, *Salmalia*, etc.). Occasionally does damage to tomatoes in kitchen gardens. Also takes insects — beetles, flying ants, etc. in awkward aerial sorties from tree-tops, and has been recorded devouring a lizard. **VOICE AND CALLS.** Monotonous, almost incessant throughout the hotter parts of the day especially in the summer months. Calling begins with a harsh *kr-r-r-r* and settles down to a steady unvarying *kithoo*, *kithoo*, *kithoo* or *kithuk*, *kithuk*, *kithuk* (or *poock*, *poock*, etc.); it is promptly joined by other birds within a ceshor and continued as an uneven chorus. **BREEDING.** Season, February to June, chiefly March to May. Nest, a hole in a rotten vertical branch or tree-stem usually excavated by the birds themselves, at heights between c. 3 and 15 meters. Eggs, normally 3 — occasionally 2 or 4 — pure white longish ovals. Average size of 30 eggs 29.3 x 22.3 mm (Baker). Laid on bare wood at bottom of shaft or on a scanty bed of chips fortuitously accumulated within during excavation. Both sexes work at drilling the hole; share in incubation, incubation period, and other facets of breeding biology uninteresting. **MUSEUM DIAGNOSIS.** Nostrils exposed; rictal and chin bristles well developed. Wings short and rounded; tail graduated. For details of plumage see Baker, loc. cit.; for subspecies Key.

COLOURS OF BARE PARTS. Its brown to Indian red; orbital skin bright orange (paler and more yellow in non-breeding season). Bill orange-brown, darker at tip (S.A.) **SIZE.** Mylna +; length c. 27 cm (10½ in.). **FIELD CHARACTERS.** As of 780, q.v. See Museum Diagnosis. **STATUS, DISTRIBUTION AND HABITAT.** Resident. Kerala and southern Tamil Nadu, mostly in the moist-deciduous low country and foothills, sometimes up to c. 1200 m. Ceylon — widely distributed and plentiful throughout the lowlands and lower hills to c. 1500 m. Habitat as in the other races.

HORNBILLS

145

expanded tail. Flight silhouette differs from that of *Aceros* (771) which has fuller and quicker wing-strokes, more like the smaller Grey hornbills (767, 768). Loud scraping noise produced by the pinions, both in flapping and gliding, audible at considerable distances. Is usually very wary and difficult to approach due to persecution by local tribals for its flesh (adults, and squabs taken from nest), considered by Hume 'far superior to any fowl or pheasant'. This, added to the increasing destruction of its native rain-forest habitats, especially in its peninsular range, is producing a marked decline in its numbers. Occasionally flies at great heights and for considerable distances across forest-clad valleys. Arrives at roost punctually about sunset by the same route day after day, the birds following one another strung out irregularly 20 to 100 metres apart. Roosts among the topmost branches of lofty thinly foliated trees, the individuals not clumped together but distributed over several neighbouring trees in a grove, 3 or 4 birds in each tree a few metres above or below one another, each constantly changing position till late in the dusk. They sleep with the neck pulled into the shoulders and bill pointing at an upward angle.

Food. Chiefly wild figs (*Ficus*), nutmegs (*Myristica*) and drupes of various species, some of very large size. Also miscellaneous animal items — lizards, snakes, rats, and nestling birds marauded from tree-holes. When too large to manage, the struggling victim is battered into submission, then flicked up in the air from the bill-tip, caught in the gullet and bolted down.

VOICE AND CALLS. Deep hoarse grunts and resounding 'barks' and roars. A very loud reverberating *tok* repeated at slow but regular intervals, with the neck stretched vertically up and bill pointing to the sky. Particularly noisy at the commencement of the breeding season.

BREEDING. Season, March–April in the Himalayas; February to April in SW. India. Nest, an unlined natural hollow in a giant forest tree such as *Calophyllum tomentosum* or *Cullenia excelsa*, and other lofty species, between 18 and 25 m up. Entrance walled up chiefly by the female herself from within, with an amalgam of her dung and remains of figs, bits of leaves and sticks possibly supplemented with wet mud brought by the male, as in Grey Hornbill, the plaster drying to the consistency of sun-baked clay. A narrow slit is left in the wall through which the male feeds the female throughout the period of her self-incarceration, and through which she, and later the squabs, shoot out their excreta with some force. Location of nest often betrayed by these excreta and remains of food littered on the ground below. When chicks about a fortnight (?) old, the wall is broken down (by ?), the female makes her exit and thereafter both parents forage for the young. Usually the wall is rebuilt as before. Female moults her rectrices and remiges while imprisoned within, but details of the process need further study and elucidation. Eggs, usually 2 sometimes only 1, (rarely 3, *vide* Baker); coarse-textured, white or creamy white, becoming stained and dirty during incubation. Average size of 44 eggs 65.1 × 45.3 mm (Baker). Period of incubation undetermined; said to be c. 31 days. If unmolested the same site is used year after year, tending to become almost traditional.

MUSEUM DIAGNOSIS. The white feathers of the foreneck and wing-bands are often tinged with bright yellow due to the bird's habit of smearing them with an oily lipid exudation from the uropygial gland while preening.

BARBETS

147

MEGALAIMA VIRENS (Boddaert): GREAT BARBET

Key to the Subspecies

Colour of head blue without any green tinge	Page
1 General coloration palest; yellow-streaked hindneck collar well developed	147
2 Darker, more richly coloured; pale streaks on hindneck few	149
3 Darkest, most richly coloured; with a greater amount of black on culmen	149

777. *Megalaima virens marshallorum* Swinhoe

Megalaima marshallorum Swinhoe, 1870, Ann. Mag. Nat. Hist. 6 (4): 348 (Himalayas) Baker, FBI No. 1427, Vol. 4: 106

LOCAL NAMES. *Traiho* (Hindi, Himachal Pradesh); *Mweli* (Mussooree); *Nyahul*, *Néul* (Nepal); *Kun nyong* (Lepcha).

SIZE. Myna +; length c. 33 cm (13 in.).

FIELD CHARACTERS. A gaudily coloured rather clumsy arboreal bird with heavy ungainly yellow bill surrounded by prominent bristles at base. Above,

× c. 1

maroon-brown with violet blue-black head; below, olive-brown, blue, and yellow with a bright scarlet patch under the tail (coverts). Sexes alike. Dipping woodpecker-like flight and expanded triangular tail proclaim it as a barbet.

STATUS, DISTRIBUTION and HABITAT. Common resident, with seasonal altitudinal movements. From Murree and the Salt Range in Rawalpindi dist., W. Pakistan, eastward in the Himalayas through Kashmir, Himachal Pradesh, Garhwal and Kumaon to western Nepal where it intergrades with *magnifica* (778); between c. 1000 and 3000 m in summer, at lower elevations and in the foothills in winter. Affects moist temperate forest.

GENERAL HABITS. Keeps singly or in small feeding parties of 5 or 6 to tall trees, but will descend into lower bushes where fruits attract, and even venture into open hill orchards and cultivation environs. Gatherings of up to 30 or more frequently collect in large fruiting trees. In spite of its gaudy coloration becomes astonishingly camouflaged amongst the foliage and is difficult to see when silent, as mostly in winter, since it usually selects the topmost branches and sits quite motionless. Has a habit, when alarmed

146

PICIFORMES

MEASUREMENTS	Wing	Bill (from forehead)	Tarsus	Tail
♂ ♀	500–552	330–375	73–75	380–432 mm
Longest casque 192; widest 106; highest 56 mm.				
COLOURS OF BARE PARTS. Male. Iris blood-red. Bill and casque yellow, tinged with red at tip and with orange in middle; front and back of casque black, together with ridge of bill just in front of casque. Female. Iris pearly white. Back of casque red. In both sexes circumorbital skin fleshy pink; eyelids black. Legs and feet greenish plumbeous (Whistler).				

Order PICIFORMES

For morphological details etc. see Stresemann, E., 1927–34, *Acet*: 839–43; Baker E. C. Stuart, 1927, FBI 4: 2; Witherby *et al.*, 1938, 2: 276.

Family CAPITONIDAE: Barbets

For description see Van Tyne, J., and Berger, A. J., 1959: 481; Dorst, Jean, 1964, Article 'Barbet' in Thomson, A. L. (ed.), *New Diet. Birds*, London & New York. For some aspects of taxonomy and relationships, see Goodwin, Derek, 1964, *Ibis* 106: 198–220.

Genus MEGALAIMA G. R. Gray

Megalaima G. R. Gray, 1842, Appendix to List Gen. Bds.: 12. Type, by original designation and monotypy, *Bucco grandis* Gmelin = *Bucco virens* Boddaert (Baker)

Prevailing colour green. Bill stout; culmen rounded, somewhat arched but never keeled. Nostrils either covered with plumes and bristles or exposed; base of bill completely surrounded by rictal bristles of moderate length, in some species long and reaching almost or quite to tip of bill. A naked orbital patch usually present. Wings rounded. Tail square or graduated. Sexes alike.

Key to the Species

	Page
I Under tail-coverts red	147
II Under tail-coverts green

3 Throat yellow, cheeks blackish	163
4 Throat orange, cheeks blue	161

148

PICIFORMES

or suspicious, of dropping like a stone from a tree overhanging a hillside into the valley below before making across to the opposite side. In summer the forest-clad hillsides and valleys resound with its endless wailing choruses, yet even then the bird is seldom seen except in flight. Flight swift and strong — a few rapid flaps followed by a drop with wings closed producing sweeping undulations as in a woodpecker. The wings produce a whirring noise like a green pigeon's, as the birds slit from one fruiting tree to its neighbour.

Food. Chiefly fruit — drupes and berries; insects — beetles, cicadas, flying termites, hornets — captured in clumsy aerial sorties from tree-tops. Flower petals, e.g. rhododendron, avidly eaten, the whole flower being first revolved and crushed in the mandibles and compacted into boluses of crumpled petals.

VOICE AND CALLS. A mournful wailing *piho*, *piho* or *piāo*, *piāo* (*pihow*) of great volume and far-reaching quality, uttered monotonously and incessantly (about 30 times per minute) throughout the day in irregular choruses by several scattered birds. Calling commences with a husky, halting *piho* as if the performer was clearing his throat in preparation. A bird will call from the same perch for an hour or more at a stretch punctuated only by momentary pauses. While calling the beak is tightly closed, the throat swells gradually almost to the size of a golf ball and deflates and inflates in a very curious way. The mechanics of the process needs investigation. A rapidly repeated gull-like *gyok gyok gyok* and a harsh *karr-r* (Magrath); occasion and significance of these calls not suggested.

Duetting is common: one bird (?) repeats *tūk, tūk, tūk* (rather like a Copper-smith barbet but faster) at about two per second; its partner (♂?) accompanies this with a perfectly timed *pihow, pihow, ad nauseam*. Both these calls sometimes also given solo. Particularly noisy at sunset when the valleys resound with their wailing from all sides.

(For a good account of habits, food and nesting see Dodsworth, P. T. L., 1911, JBNHS 31: 681–4.)

BREEDING. Season, April to July; earlier at lower elevations, later higher up. Nest, an unlined hollow in the bole or upright bough of a forest tree 3 to 5 m up, occasionally much higher; usually excavated by the birds themselves — sometimes a disused woodpecker hole. Diameter of entrance c. 8 cm, of egg-chamber c. 18 cm; shaft normally quite deep — between 30 and 45 cm. Eggs, 3 or 4, white, longish ovals. Average size of 25 eggs 34.0 × 24.9 mm (Baker). Share of the sexes in incubation, and period, undetermined. Both parents feed the nest-young.

MUSEUM DIAGNOSIS. For details of plumage see Baker, FBI 4: 104 and loc. cit.

MEASUREMENTS	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	146–152	c. 46	c. 23	100–109 mm (Baker)
		(from skull)

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 780, q.v.
BREEDING. Season, in Kerala chiefly February to April; in Ceylon February to October, 'chiefly March-April and again during September and October' (Phillips). *Nest* and *eggs* (normally c/3) as in the other races. Average size of 18 eggs 30.9 × 23.7 mm (Baker).

MUSEUM DIAGNOSIS. Differs from the adjacent subspecies *inornata* (781) in having the chin, throat and breast rather darker brown and more conspicuously streaked with pale shaft-streaks. It is also slightly smaller.

MEASUREMENTS (of Ceylon birds)

	Wing	Bill (from skull)	Tarsus	Tail
7 ♂♂	106-113	30-33	27-29	61-69 mm
8 ♀♀	110-118	32-36	27-29	63-71 mm (HW)

Weight 1 ♂ 87 g (SDR):

COLOURS OF BARE PARTS. As in *M. z. caniceps* (780).

MEGALAIMA LINEATA (Vieillot): LINEATED BARBET

Key to the Subspecies

Darker *M. l. rana*
 Paler *M. l. hodgsoni*

Cf. Ripley, S. D., 1950, *tom. cit. infra*: 101-2 (ranges of forms in Nepal).

783. *Megalaima lineata rana* Ripley

Megalaima zeylanica rana Ripley, 1950, Proc. Biol. Soc. Washington 63: 101

(Bajora, Dailekh dist., west Nepal)

Baker, FBI No. 1432 (part), Vol. 4: 111

LOCAL NAMES. *Kūdürta*, *Khotoor* (Nepal); *Bādā bārāntā*, *Kolūr* (U.P.).

SIZE. Myna +; length c. 28 cm (11 in.).

FIELD CHARACTERS. As of 784. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident. The Himalayan submontane tract from the edge of the terai and through the foothills up to c. 1000 m; from Kumaon (Dehra Dun dist.) to west-central Nepal. Apparently replaces the subspecies *hodgsoni* in west-central Nepal at levels above the terai. Affects moist-deciduous biotope.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in *M. l. hodgsoni* (784), q.v.
BREEDING. Season, end March to middle June: most eggs in first half April. *Nest* and *eggs* (c/2-4) as in 784.

MUSEUM DIAGNOSIS. Very similar to *M. l. hodgsoni*; originally described as larger and darker.¹

MEASUREMENTS

	Wing	Bill (from skull)	Tail
8 ♂♂	128-135	34-36 (4 msd.)	78-82 mm (4 msd.)
8 ♀♀	128-142	34-37 (4 msd.)	77-85 mm (4 msd.) (DB, Fleming)

¹ But not readily distinguishable; validity of the subspecies considered equivocal by some authorities.

BARBETS

155

and 12 metres; diameter c. 8 cm, depth up to 50 cm ending in a widened egg chamber. *Eggs*, 2 to 4, white, elongated ovals averaging c. 32 × 23 mm. Laid on the bare wood or a scanty bed of fortuitously fallen-in chips. Both sexes share in excavating the hole, incubation, and feeding the young. Period of incubation undetermined: estimated to be 14 or 15 days.

MUSEUM DIAGNOSIS. Very similar to *M. z. caniceps* (780) but with much broader pale streaks above and below. Pale spots and striations on upperparts confined to extreme upper back. Bare patch round eye smaller and separated from base of bill by a broad line of feathers. Differs from *M. l. rana* (783) in being slightly smaller (?) and paler.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂♀	123-137	30-33	29-30	82-86 mm (Baker)

A large series from Nepal, Bhutan and Buxa duars ♂♀ Wing 119-139 mm (Ticehurst).

Weight 1 ♂ 139 g; 2 ♀♀ 149, 170 g (Paynter).

COLOURS OF BARE PARTS. Iris brown; eyelids and orbital skin deep yellow. Bill horny yellow, culmen and tip darker. Legs and feet fleshy yellow to orange-yellow.

785. *Small Green Barbet. Megalaima viridis* (Boddaert)

Bucco viridis Boddaert, 1783, Table Pl. enlum.: 53

(Mahe, India ex Daubenton, pl. 870)

Baker, FBI No. 1434, Vol. 4: 113

Plate 60, fig. 2

LOCAL NAME. *Chhōlā bāsānthā* (Hindi).

SIZE. Myna ±; length c. 23 cm (9 in.).

FIELD CHARACTERS. A dumpy grass-green bird very similar to and easily confused with Large Green Barbet (781) but white cheek-stripe diagnostic even at a distance.

Above, crown and nape dark brown with a blackish band running backward from eye, a short white supercilium, and a broad white stripe from the lores through the ear-coverts. Below, chin and throat whitish; breast whitish streaked with brown; abdomen and vent pale green. Naked orbital patch much smaller than in 781 and blackish brown (v. orange). Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Resident; common. The Sahyadri or Western Ghats complex (including Nilgiri and Palni hills) from Kerala northward to about the Narbada river; extends east in southern peninsular India to the Shevaroy and Chitteri hills (Tamil Nadu). Evergreen and moist-deciduous biotope, from plains level to c. 1500 m (the commonest barbet at Mahabaleshwar). Occurs up to c. 1800 m in the Nilgiris, occasionally to 2300 m. Affects wooded country; also gardens and groves in the neighbourhood of towns, villages and cultivation.

GENERAL HABITS. Very similar to the larger Green Barbets, *M. zeylanica* and *M. lineata*, qq.v. Usually keeps in pairs and small parties, but 20 to 30 birds or more will collect on a fruit-laden banyan or peepul tree to feast in company with bulbuls and other frugivorous birds. Is of a quarrelsome disposition and given to continual bickering and fighting with its fellow

(Chahala, Simlipal Hills, Orissa)

Baker, FBI No. 1432, Vol. 4: 111

Plate 60, fig. 1

LOCAL NAMES. *Kūdürta*, *Khotoor* (Nepal); *Dang kim nyong* (Lepcha); *Das tikra* (Cachari); *Inruikūru* (Kacha Naga).

SIZE. Myna +; length c. 28 cm (11 in.).

FIELD CHARACTERS. A dumpy stout-billed grass-green arboreal bird, very similar to Green-Barbet (780) but much more broadly pale-streaked above and below; naked yellow patch around eye much smaller and less conspicuous, not extending to the gape. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Resident. West-central Nepal (where it apparently occurs at lower levels than *rana*), east through northern Bihar, West Bengal, Sikkim, Bhutan, Assam, Manipur, and East Pakistan from c. 800 m down to the terai, duars and the lowlands, and south to the Orissa hills. Affects moist-deciduous biotope frequenting light secondary forest as well as well-wooded gardens, roadside avenues of *Ficus* trees, etc.

Extralimital. Burma, Thailand, the Indochinese countries and Malay Peninsula.

GENERAL HABITS. Very similar to Green Barbet (780 and races), from which it is seldom differentiated in the field by casual birdwatchers. Keeps singly or in loose feeding parties on fruiting *Ficus* and suchlike trees in company with other frugivorous birds. Extremely noisy in the hot weather, its resounding choruses, joined in by several birds within earshot of each other, continued practically without intermission throughout the day, with occasional bursts during moonlight nights as well. Flight, as typical of the barbets, noisy, rather heavy and dipping.

FOOD. Mainly fruits of all kinds [including *phalsa* (*Grewia*) in low bushes and strawberries on the ground]; flower nectar (e.g. *Salmalia* and *Erythrina*); insects — termites, larvae and grubs — and small animals such as lizards and tree-frogs on occasion.

VOICE AND CALLS. Very similar to the Green Barbet's and doubtfully recognizable as different when casually heard. On a critical listening-in perhaps rather mellow and softer, sounding more like *kōtūr*, *kōlūr*, *kōtūr* than *kūtrū* or its other renderings (see 780); also a variety of guttural chuckles expressive of anger, agitation and other emotions. Baker describes 'a loud musical whistle apparently only used to call together scattered members of a family flock', which we have not heard.

BREEDING. Season, end March to mid June, the peak periods varying locally. *Nest*, a hole cut into a rotten branch or snag at heights between 3

156

PICIFORMES

feasters. Frequently clings to trunks and boughs of trees, climbing up like a woodpecker.

FOOD. Mainly fruit, especially *Ficus* figs, but it is also largely insectivorous. Often makes serious raids on kitchen gardens and orchards. Alleged to cause considerable waste in S. Indian coffee estates by guzzling the ripe 'cherries' and scattering the valuable seeds or 'berries', but extent of damage unduly exaggerated. Regularly takes insects on tree-trunks, and flying termites in mid-air by clumsy aerial sorties from tree-tops. Is also fond of flower nectar — *Erythrina*, *Grevillea*, *Bombax*, etc., and may be incidental in their cross-pollination.

VOICE AND CALLS. Calling starts with a loud explosive *pitrr-rrr* (c. one second). Notes confusingly like the larger Green Barbets' (qq.v.), perhaps slightly higher in key but hardly distinguishable unless heard side by side. Also sounds more like *pūcock*, *pūcock*, *pūcock*, etc. (c. two per second) than the *kūtrōo*, *kūtrōo* of the former. Particularly obstreperous in the breeding season, calling incessantly from dawn till dusk, some individuals often continuing far into or throughout moonlit nights. As soon as one bird begins calling a second some distance away promptly chimes in, followed by a third and a fourth and so on till the forest resounds with an almost deafening uneven chorus. Occasionally utters a single note *tūk*, very like the Copper-smith's (792).

BREEDING. Season, overall December to June; principally between December and March in the southern part of its range. *Nest*, similar to that of the other Green Barbets — a hole in a rotten branch or snag excavated by the birds themselves, almost any height from the ground between 2 and 10 metres; occasionally higher. It is not unusual to find several holes in the same tree, in some cases leading to the same chamber and apparently drilled in different years. *Eggs*, usually 3, sometimes 2 or 4; pure white regular ovals as characteristic of the barbets. Average size of 30 eggs 26.2 × 20.3 mm (Baker). Frequently two broods are raised. Both sexes incubate and feed the young, at first by regurgitation and when older on entire berries. Incubation period 14-15 days; fledging period c. 36 days (S. A. Yahya).

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit. Has a complete post-nuptial moult and no spring moult. Worn birds are paler in colour especially on crown and breast, the latter becoming much whiter with the wearing off of the brown margins to the feathers.

Young (immature) like adult but the streaking on head and breast less well-defined and head rather paler.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♀	97-113	24-29	c. 27	65-70 mm (SA, HW, Koels)

Average of Wing 19 ♂♀ 103 mm. There is no significant difference in size between birds from the northern and southern parts of the range.

Weight 16 ♂♀ 71-90 (av. 80.5) g — Grubb.

COLOURS OF BARE PARTS. Iris chestnut-brown to dark brown; eyelids and circumorbital skin slaty brown or slaty black. Bill brownish flesh colour, browner on culmen, plumbeous at gape; mouth pinkish grey. Legs and feet greenish grey; claws horny brown.

MISCELLANEOUS. Parasitized by thick *Harmaphysalis spinigera* (Rajagopalan, JBNHS 69: 62).

BARBETS

157

786. Yellowfronted Barbet. *Megalaima flavifrons* (Cuvier)

Bucco flavifrons Cuvier, 1817 (1816), Règne Anim.: 423, note 2
(Ceylon. Based on Levaillant, Ois. de Paradis, pl. 55)

Baker, FBI No. 1440, Vol. 4: 120

Plate 60, fig. 7

LOCAL NAMES. *Mūkalāṅg kottāruwā* (Sinhala); *Kūṭūr*, *Kūkkuruvān* (Tamil).

SIZE. Myna —; length c. 21 cm (8½ in.).

FIELD CHARACTERS. Similar to Green Barbet (782) but slightly smaller: dark grass-green above with golden yellow forehead and verditer-blue face and throat. Below, pale green, the breast feathers boldly scalloped with emerald-green, producing a scaly pattern. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Endemic to Ceylon. Plentiful but locally distributed in the low-country Wet zone and in parts of the Dry zone (especially in the Eastern Province). Generally abundant in the hills to c. 2000 m. Affects forest.

GENERAL HABITS. Similar to Green Barbet (782), q.v.

FOOD. Mainly *Ficus* figs, and various drupes and berries. Does considerable damage to fruit in orchards, of which it is a minor pest. Occasionally also takes animal food — insects, lizards, etc.

VOICE and CALLS. The call which resounds in the forest 'commences with a rolling and ascending *houwouououou* and changes to *kuiār*, *kuiār*, *kuiār* . . . repeated many times; it is always answered by the performer's mate [?] from perhaps a hundred yards away' (Henry). Cf. 785.

BREEDING. Season, not well defined; breeds practically throughout the year but chiefly March to May and again during August and September (Phillips). Nest and eggs (cf 2 or 3) as in Green Barbet, the latter pure white and oval with a smooth texture. Average size of 38 eggs 26.6 × 20.7 mm (Baker); apparently laid at intervals of more than 24 hours judging from the disparity in the nestlings.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	87-93	21-25	22-25	52-58 mm (HW)

Weight 2 ♂♂ 57, 60 g (SDR).

COLOURS OF BARE PARTS. Iris light red. Bill greenish horn colour, darker about the nostrils. Legs and feet greenish or bluish.

787. Goldthroated Barbet. *Megalaima franklinii franklinii* (Blyth)

Bucco Franklinii Blyth, 1842, Jour. Asiat. Soc. Bengal 11 (1): 167 (Darjeeling)

Baker, FBI No. 1444, Vol. 4: 124

Plate 60, fig. 6

LOCAL NAMES. *Bānbāsi*, *Bāghbāsi* (Nepali); *Dao yāla* (Cachari).

SIZE. Myna; length c. 23 cm (9 in.).

FIELD CHARACTERS. A dumpy grass-green barbet with crimson and bright golden crown, grey ear-coverts, and a broad black supercilium from bill to

BARBETS

159

vertex. Crown behind this crimson, with a black streak on either side running back to nape. A short supercilium and feathers round eye, ear-coverts, chin and throat, verditer-blue. A crimson speck on either side at base of lower mandible; a crimson patch at base of throat on either side. Base of bill surrounded by conspicuous black bristles. Sexes alike.

The subspecies described and illustrated by Stuart Baker (Fauna 4: 119) as *Cyanops asiatica rubescens* from the Khasi and Cachar hills, Manipur etc. and sporadically met with also in Bhutan and elsewhere in the eastern Himalayas is merely a variant of the nominate form. It is 'Similar to *C. asiatica asiatica* but with the upper parts suffused with crimson; the under parts flecked and streaked with crimson, though in varying degree and generally less so in females than in males'.

STATUS, DISTRIBUTION and HABITAT. Resident; common. The lower Himalayas from W. Pakistan Punjab (Rawalpindi dist.) and Kashmir eastward through Himachal Pradesh, U.P., Nepal, Sikkim, Bhutan and NEFA. Also Bengal (common in Calcutta City), Assam, Nagaland, Manipur, Mizo Hills and East Pakistan; from plains level to c. 2000 m. In the Himalayas occupies a lower altitudinal zone in summer than Goldthroated Barbet (787). Affects well-wooded country — light deciduous and evergreen forest and groves of trees (especially *Ficus*) around villages and in urban gardens.

Extralimital. Extends south to Burma and the northern Shan States. Other races in Yunnan, Thailand, Indochinese countries and Borneo.

GENERAL HABITS. Not appreciably different from those of the Large and Small Green barbets, qq.v.

FOOD. Mainly fruits; occasionally mantises and other large insects which are whacked limp against the perch before swallowing.

VOICE and CALLS. Casually almost indistinguishable from those of Large Green Barbet (780); critically, softer and in a somewhat higher key, sounding more like *pūkūrik*, *pūkūrik* (3 syllables) more rapidly repeated than *pecock* or *kūrik* (2 syllables) of the former; often ends in a rippling *kū-rrr*. In the distance sometimes strangely reminiscent of the rattling call of Red Spurfowl (275), q.v., but less loud and more 'nutty'. Song also described as *kool' toodzedoo* . . . repeated *ad nauseam*, the first note lower, the three others rapidly uttered (Desfayes). Indulges in the same irregular duets and choruses, confused and made still noisier by both the species often calling together in the same locality.

BREEDING. Season, overall March to June/July, varying with altitude. Nest, the typical barbet hole excavated in a dead tree-trunk or decaying branch, between 2 and 8 metres up. When in a horizontal branch the

158

PICIFORMES

nape. Chin and throat golden yellow with an orange spot on each side of base of bill near gape. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Resident. The Himalayas from Central Nepal eastward through Sikkim, Bhutan and NEFA. Also Cachar, Nagaland, Manipur and Mizo hills; East Pakistan in the Chittagong Hill Tracts. Affects forested hillsides normally between c. 600 and 2400 m. Inhabits a higher altitudinal zone in summer than the Bluethroated Barbet.

Extralimital. Northern Burma, southern Yunnan, northern and central Vietnam and northern Laos (Peters). Other races in Thailand and Malay Peninsula.

GENERAL HABITS. Not appreciably different from the Green and Bluethroated barbets, qq.v. Arboreal, noisy, and gregarious when feeding on fruit-laden trees.

FOOD. Mainly fruit; occasionally insects.

VOICE and CALLS. Various rendered: a wailing *pegu, pegu*, etc. reminiscent of the calls of the Great Barbet (777) but somewhat higher pitched, reiterated monotonously for considerable periods. A single note *wook* (as in owl) preceded by an undertone *pk* or *pik* audible only at close quarters, thus actually *pik-wook*, repeated for many minutes at a stretch in intermittent runs. Calling begins with a rolling *krrr-krrr* and settles down to a monotonous *pūkūwok*, *pūkūwok*, *pūkūwok*—*ad nauseam*.

BREEDING. Season, April to June, mostly during May. Nest, the usual barbet hole in a dead tree-stump or rotten branch between 2 and 5 m up, excavated by the birds themselves. Eggs, 3 or 4, white, rather long to broad blunt ovals. Average size of 50 eggs 27.4 × 21.1 mm (Baker). Both sexes share in drilling the hole, incubation, and feeding the young. Period of incubation undetermined.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂ ♀	97-109	23-28 (from skull)	24-28 (SA, BB, Stresemann)	59-68 mm

Weight 6 ♂♂ 79-101 g; 5 ♀♀ 72-94 g (SA, Paynter).

COLOURS OF BARE PARTS. Iris brown. Bill black, greyish at base of both mandibles. Legs and feet greenish slate; pads dull yellow.

788. Bluethroated Barbet. *Megalaima asiatica asiatica* (Latham)

Bucco cyanotis Blyth, 1847, Jour. Asiat. Soc. Bengal 16 (1): 465 (Arakan)

Cyanops australis viridis Deignan, 1941, Auk 58: 398 (Pang Makhm Phong, foot of Doi Pha, Sakaeng, Siam)

Cyanops robustirostris Baker, 1896, Jour. Bombay nat. Hist. Soc. 10: 356, pl. F (North Cachar Hills)

Cf. Ripley, S. D., 1953, *Ibis* 95: 547-8

Baker, FBI No. 1443, Vol. 4: 123

Plate 60, fig. 11

LOCAL NAME. *Dao tikra kashiba* (Cachari).

SIZE. Sparrow +; length 17 cm (6½ in.).

FIELD CHARACTERS. A small bright grass-green barbet distinguished chiefly by its gaudy multicoloured head-pattern. 'Whiskers' (narial bristles) projecting beyond tip of bill. Lores, forehead and forecrown black, the feathers fringed with pale blue; hindcrown cobalt blue. Ear-coverts pale verditer-blue with a crimson patch above and another below. Chin and throat pale verditer-blue. An area below eye mixed yellow and bright red divided from chin by a black moustachial stripe. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Resident. E. Nepal, Sikkim, northern Bengal, Bhutan, Assam, Nagaland, Manipur, Mizo (?), East Pakistan (Chittagong Hill Tracts); terai, duars, and foothills up to c. 1200 m. Affects thick evergreen forest.

Extralimital. Burma south to northern Tenasserim, Thailand, and the Indochinese countries.

GENERAL HABITS. Similar to those of the Crimsonbreasted Barbet or Coppermith (792), q.v., though more restricted to heavy jungle. Usually seen singly, perched on the very summit of some tall tree whence it keeps calling for hours at a time (Davison).

BARBETS

161

FOOD. Mainly fruits; occasionally some insects.

VOICE AND CALLS. A peculiar, somewhat harsh metallic double note *koo-turr, koo-turr* or *loo-rook, loo-rook* unlike that of any other barbet, but closer in pattern to that of the Green, endlessly repeated.

BREEDING. Season, April, May and early June. Nest, the typical barbet excavation in a dead tree-trunk or branch, usually in dense forest. Eggs 2 to 4, white; probably laid at longer than 24-hour intervals. Average size of 40 eggs 24.5 × 18.3 mm (Baker). Both sexes share all the domestic chores. Period of incubation undetermined.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

Young (immature) has the whole head green, washed with blue on throat and sides of head.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	77-85	18-21	c. 21	45-50 mm (Baker)

Weight 5 ♂ ♀ 32-38 g (Paynter).

COLOURS OF BARE PARTS. Iris dark brown or reddish brown. Bill dark horny brown, yellowish green on base and gape, black on culmen and tip. Legs and feet dull green, or yellowish green to slaty green.

SIZE. Sparrow +; length c. 17 cm (6½ in.).

FIELD CHARACTERS. A small dumpy grass-green barbet with yellow throat, crimson breast and forehead, and green-streaked yellowish underparts. Short, truncated tail, distinctly triangular in flight-silhouette. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Resident; common and very widely distributed. Practically throughout the Indian Union (including Assam and Manipur), both Pakistans, Nepal, Sikkim, Bhutan (terai and lowlands),

and Ceylon; plains and foothills to c. 2000 m in dry- and moist-deciduous biotope. Rare in the arid portions of Sind, Punjab, Rajasthan and Kutch. Largely replaced in the heavy-rainfall areas of the southern Western Ghats by *M. r. malabarica* (790). Affects the lightly wooded countryside, roadside avenues and groves of trees (especially *Ficus* species) near villages and cultivation, and in urban gardens and compounds.

Extralimital. Southern Yunnan, northern Malaya, Thailand and the Indochinese countries. Other races in the Philippine and Indonesian islands.

x c. 1

162

PICIFORMES

GENERAL HABITS. Except for its adaptation to an evergreen biotope, not appreciably different from the better known Coppersmith (792), q.v. Its moister habitat coincides with that of Small Green Barbet in the same way as the Coppersmith's does with that of *M. zeylanica* (782). Gregarious in non-breeding season. Very numerous in south Indian coffee estates where *Ficus* trees are grown as shade, consorting with green pigeons, mynas and other frugivorous birds to feed on the figs. In flight from treetop to treetop mistakable for lorikeet, with similar rapid fluttering when alighting.

FOOD. Wild figs, drupes and berries; doubtless also insects on occasion but this not specifically recorded.

VOICE AND CALLS. Indistinguishable from Coppersmith's — a metallic *tūk . . . tūk* or *tūnk . . . tūnk* etc. repeated monotonously for many minutes; perhaps a trifle softer and also quicker in tempo.

BREEDING. Season, January to March. Nest and eggs (normally 2, sometimes 3) indistinguishable from those of Crimsonbreasted Barbet (792). Average size of 10 eggs 24.7 × 17.7 mm (Baker). Incubation by both sexes; period 14-15 days, fledging c. 36 days (S. A. Yahya).

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

Young (immature). Like adult but duller, with the whole head green or only with yellow traces of the crimson patches of adult. Young indistinguishable from that of the nominate subspecies of Ceylon (791).

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	78-88	15-18	17-20	35-39 mm (SA, Baker)

COLOURS OF BARE PARTS. Iris brown. Bill: upper mandible horny brown; lower pale flesh colour at chin, plumbeous at gape and sides except near terminal portion which is brownish; mouth greyish pink. Legs and feet coral pink; claws horny brown.

MISCELLANEOUS. Parasitized by tick *Haemaphysalis spinigera* (Rajagopalan, JBNHS 69: 62).

791. *Megalaima rubricapilla rubricapilla* (Gmelin)

Bucco rubricapillus Gmelin, 1788, Syst. Nat. 1 (1): 408 (Ceylon)
Baker, FBI No. 1449, Vol. 4: 130
Plate 60, fig. 10

LOCAL NAMES. *Māl kottūrūv* (Sinhala); *Sinna kutturūv* (Tamil).

SIZE. Sparrow +; length c. 17 cm (6½ in.).

FIELD CHARACTERS. Similar to Crimsonthroated Barbet (790) but with chin, throat, supercilium and patch below eye orange-yellow instead of crimson. Crimson patch on foreneck, and rest of underparts, as in 790. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Subspecies endemic to Ceylon. Plentiful throughout the Wet zone and in many areas in the Dry zone and lower hills to c. 1300 m (Phillips). Affects openly wooded country with a scattering of *Ficus* trees.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 790, q.v. The sustained, monotonous calling is described by Henry as 'sometimes a slow *wok, wok, wok* . . . , but more often a rapid, throbbing *pop op op op op op, pop op op op*

164

PICIFORMES

GENERAL HABITS. Like other barbets entirely arboreal and eminently frugivorous. Keeps solitary or in pairs and parties of a dozen or so — sometimes large gatherings of up to a hundred or more on abundantly fruiting *Ficus* trees — in company with bulbuls, mynas, green pigeons and other fruit-eaters. Fond of sunning themselves in the morning on bare top branches of tall trees in between spells of feeding, sitting inert or flitting about to perch near one another. Comparatively silent in winter, its calls becoming ubiquitous as the hot season waxes; particularly vocal during the hotter parts of the day. A spell of rain or cold immediately silences the birds. Flight straight, with rapid flaps, rather like a finch in distant silhouette particularly when several are flying off together from a tree-top as after sunning.

FOOD. Banyan, peepul and other wild figs; various drupes and berries. Occasionally moths and flying termites captured in clumsy aerial sorties.

VOICE AND CALLS. A loud rather metallic *tūk* (or *tūnk*) . . . *tūk . . . tūk* and so on, reminiscent of a distant coppersmith hammering on his metal. Repeated monotonously for long periods, the tempo varying with the prevailing emotion from about twice a second to three in two seconds. Has been timed as fast as 108 to 121 *tūks* per minute and repeated 204 times without a break. When the spacing is correct, sounds exceedingly like the time-signal pips of All-India Radio! The calls usually start with a very subdued *tūk* and steadily work up to an even pitch in volume and tone. The bird's beak remains shut: a patch of bare skin on either side of the throat inflates like a rubber bulb and collapses with each *tūk*, the feathers of the crimson breast-patch standing out like a short beard; the whole body, especially tail, is jerked and the head bobbed and turned from side to side producing a curious ventriloquistic effect.

BREEDING. Season, overall November to June, mainly February to April; in Ceylon, December to September, mainly from February; often two broods raised in quick succession. Nest, a shaft excavated in a dead or decaying softwood branch or snag (*Moringa*, *Erythrina*, *Pongamia*, *Salmalia*, etc.) c. 25-80 cm deep — usually c. 40 cm — ending in a slightly widened chamber. Eggs, 2 to 4, normally 3, glossless white, loughish ovals. Laid on bare wood at bottom of shaft. Average size of 100 eggs 25.2 × 17.5 mm (Baker). Both sexes share all the domestic chores. Period of incubation undetermined.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

Young (immature) similar to adult but the green is duller and rather greyish in tint. Forehead, crown, and nape uniform with rest of upperparts, i.e. lacking the red, black, and grey of the adult. Yellow above and below eye paler; black behind eye and ear-coverts, and on moustachial streak, duller and less extensive. Chin and throat greyish white tinged with yellow round the chin and sides. Breast greyish green merging into the streaking of the lower breast and flanks.

Moult. Post-nuptial complete; no spring moult. Post-juvénal moult presumably complete as first-year bird indistinguishable from adult. Wear (caused partly by the birds constantly scraping in and out of roosting and nesting holes) produces a great change in the plumage, the upperparts looking bluish green rather than yellowish green as in fresh plumage, thus offering tempting scope to enterprising creators of new subspecies!

HONEYGUIDES

165

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	78-84	16-20	17-21	33-38 mm
♀♀	75-83	17-20	18-21	30-37 mm (SA, HW)

Weight 10 ♂ 32-47 g (SA, SDR, Paynter).

COLOURS OF BARE PARTS. Iris brown; eyelids (rim) coral-red. Bill dark horny brown or black; mouth pale pinkish grey. Legs and feet coral-red; claws black; pads yellowish.

Family INDICATORIDAE: Honeyguides

For description see Van Tyne, J., and Berger, A. J., 1959: 482; Stresemann, E., 1927-34, *Aves*: 840-1; Baker, E. C. S., 1927, FBI 4: 131; Friedmann, Herbert, 1964, Article 'Honeyguide' in Thomson, A. L. (ed.), *New Dict. Birds*, London and New York.

Represented by three genera and eleven species in Africa; only a single species within Indian limits, and one in Malaysia.

(See 'The Honey-guides' by Herbert Friedmann, 1955, United States Nat. Mus. Bulletin 208, pp. vii + 292, Washington.)

Genus INDICATOR Stephens

Indicator Stephens, 1815, in Shaw's Gen. Zool. 9 (1): 131. Type, by tautonymy, *Indicator Sparrmannii* Stephens = *Cuculus indicator* Sparrman

Bill short, stout, and well curved. Tail-feathers twelve in our only species. Wing long and pointed, with nine primaries only. Ventral feather-tract forked on the throat but not on each side of the breast.

INDICATOR XANTHONOTUS Blyth: HONEYGUIDE

Key to the Subspecies*

- Paler; forehead orange-yellow.....*I. x. xanthonotus*
 Darker; yellow of forehead restricted posteriorly.....*I. x. fulvus*
 * Distinctness of *radcliffei* from nominate *xanthonotus* unconfirmed for want of additional specimens from the type locality.

793. *Indicator xanthonotus radcliffei* Hume

Indicator radcliffei Hume, 1870, Ibis: 528 (Kalabagh, Hazara dist., W. Punjab)
 Baker, FBI No. 1450 (part), Vol. 4: 131

LOCAL NAMES. None recorded.

SIZE. Sparrow; length c. 15 cm (6 in.).

FIELD CHARACTERS. As in 794, q.v.

STATUS, DISTRIBUTION and HABITAT. Presumably resident; very rare and sporadic. The Western Himalayas from the Afghan frontier (Hazara, Bannu, Murree), eastward to Garhwal, Kumaon and possibly western Nepal (but no specimens). From c. 1500 to 3000 m, possibly moving altitudinally with seasons. Affects coniferous and dry deciduous forest with cliffs and rock scarps. May possibly range above tree-line.

HONEYGUIDES

167

had laid (Diesselhorst, 1968). Presumably brood-parasitic on barbets like other honeyguide species in Africa, but breeding biology little known in India. However, a remarkable mating system, described as 'Resource-based non-harem polygyny', revealed by recent studies in E. Nepal. A male holds a bees' comb as his territory throughout the year. Copulates with females visiting comb to feed during the breeding season, April-May. Males without territory apparently seldom have a chance of mating (Cronin Jr., Edward, in *Living Bird* 1976).

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

Female. Similar to male but slightly smaller and duller: rump-patch sulphur yellow (v. bright orange-yellow); yellow areas on forehead, crown, and sides of throat paler and less extensive.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂♂	92-97	8-9	13-15	54-61
♀♀	82-92	c. 9	13-14	53-55

(from feathers)

(Friedmann, SA)

Bill from skull 3 ♂ 11.5-12 mm, 2 ♀ 11-12 mm.

Weight 4 ♂ 29-34, 3 ♀ 26-29, 3 o? 28-31 g (SA, SDR, Diesselhorst)

COLOURS OF BARE PARTS. Iris dark brown; bare circumocular area very pale green. Bill yellow, somewhat dusky terminally; at the base of both the maxilla and the mandible, as well as on the chin, black bristles are present, none present above the large, swollen, triangular nostrils. Tarsi and toes pale greenish horny (Friedmann).

795. *Indicator xanthonotus fulvus* Ripley

Indicator xanthonotus fulvus Ripley, 1951, Postilla, no. 6, Feb. 28: 2
 (Pflutero, eastern Naga Hills, Assam)
 Baker, FBI No. 1450 (part), Vol. 4: 131

LOCAL NAME. *Mephi tsu kelie para* (= the bird that eats bees, Naga) — SDR.

SIZE. Sparrow; length c. 15 cm (6 in.).

FIELD CHARACTERS. As in 794, q.v. Reminiscent of a flycatcher when perched on a tree-top. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Eastern NEFA, NE. Assam (Margherita area), Nagaland, Manipur; above c. 1500 m and at least to 2100 m, possibly higher and moving altitudinally with season. Affects denser and wetter forest than 793 and 794.

Extralimital. Northeastern Burma.

GENERAL HABITS. As in 793 and 794.

FOOD. As in 794.

VOICE and CALLS. An occasional single *weei* uttered on the wing during the aerial flycatching sallies (Smythies, *Ibis* 1949: 645).

BREEDING. Unknown.

MUSEUM DIAGNOSIS. Darker than nominate *xanthonotus*; more blackish both above and below, with the yellow of the forehead more restricted posteriorly.

MEASUREMENTS

	Wing	Bill	Tail
1 ♂	90	11	57 mm
1 ♀	86	10	56 mm

(SDR)

... brown. Bill yellowish horn, distal half of upper

166

PICIFORMES

The type of *radcliffei* was collected in June 1867 since when the bird has been observed perhaps not more than half a dozen times but no more specimens procured; the last seen was on 2.iv.1923 by Whistler at Truin, Dharmasala, c. 2900 m in oak forest (*Quercus semecarpifolia*).

GENERAL HABITS, FOOD, VOICE and CALLS. Very little known. Sits upright and motionless among top branches of trees in a dove-like attitude, head sunk on breast, plumage rather puffed out and wings drooping (Magrath, JBNHS 19: 153-4).

BREEDING. Unknown.

MUSEUM DIAGNOSIS. Distinctness of this population from nominate *xanthonotus* unconfirmed due to lack of specimens.

MEASUREMENTS and COLOURS OF BARE PARTS. As in *xanthonotus* (794).

794. *Indicator xanthonotus xanthonotus* Blyth

Indicator xanthonotus Blyth, 1842, Jour. Asiat. Soc. Bengal 11 (1): 116 (Darjeeling)
 Baker, FBI No. 1450, Vol. 4: 131

Plate 103, fig. 1

LOCAL NAMES. None recorded.

SIZE. Sparrow; length c. 15 cm (6 in.).

FIELD CHARACTERS. A sparrow-like olive-brown bird with a rather stout finch-like bill and glistening orange-yellow forehead and cheeks. Middle of back pure yellow; lower back and rump orange-yellow conspicuous when the bird sits, as is its habit, with the wings partly drooping at the sides; also contrasting strongly with dark upperparts in flight. Upper tail-coverts and tail blackish brown; under tail-coverts black, scalloped paler.

Female more or less similar.

STATUS, DISTRIBUTION and HABITAT. Resident. Evidently not uncommon, but easily overlooked. The Himalayas from east-central Nepal (Baglung dist.—Fleming) eastward through Sikkim, Bhutan and Arunachal (?), from c. 1500 to 3500 m. Also observed (ssp.?) in Garhwal (Valley of Flowers—Hussain, JBNHS 75: 487). Affects mixed broad-leaf and conifer forest in the neighbourhood of bee-nesting cliffs and rock-scarps. May possibly range above tree-line.

GENERAL HABITS. As in 793 and 795, but little known. Nothing known as to whether this species guides humans and other melliphagous animals to live bees' nests as its congeners and relations are reputed to do in Africa.

FOOD. Bees and probably other hymenoptera, taken in the air by clumsy flycatching sallies in the manner of a bulbul (Smythies). Also clings like a woodpecker to combs of rock bees when the bees are absent (e.g. in winter). Feeds predominantly on wax from abandoned combs, even on pieces fallen to ground below. Gizzards of specimens contained beeswax almost exclusively, but also some insect remains.

VOICE and CALLS. See under 795.

BREEDING. Season. The only positive indication is provided by a female collected in Nepal on May 7 (1962) with the largest of three developed ovarian follicles measuring 8 mm. Its dilated oviduct, moreover, showed that the bird

 Baker, FBI No. 1423, Vol. 4: 99

Plate 62, fig. 1

LOCAL NAMES. *Gārdān eyengtha* (Hindi); *Meda nulingadu* (Telugu).

SIZE. Bulbul —; length c. 19 cm (7½ in.).

FIELD CHARACTERS. A slim, silvery grey-brown bird, streaked, speckled and vermiculated with black and fulvous above. Below, whitish with arrow-head markings producing a finely cross-banded pattern. Tail with 3 or 4 conspicuous dark bands. Sexes alike.

Deceptively sparrow-like, particularly in flight. On a flashing glimpse also mistakable for Great Reed Warbler in the appropriate habitat.

STATUS, DISTRIBUTION and HABITAT. Winter visitor (c. September to March) to West Pakistan (Baluchistan, Sind, Punjab), Nepal terai, and

x c. 1

WOODPECKERS

169

through U.P., Rajasthan, Gujarat, Maharashtra and western central India south to Kerala (Jackson, 1967, JBNHS 64: 368). Precise subspecific determination of winter specimens often equivocal, and of sight records impossible. Recorded as passage migrant in many localities. Affects semi-desert, stunted thorn jungle, open deciduous scrub country and cultivation.

Extralimital. 'Breeds in Europe and W. Asia from S. England, N. Scandinavia, Finland, Russia and W. Siberia north to lat. 64°N. on the Yenisey and east to Lake Baikal, south to the Pyrenees, the Alps, Yugoslavia, Bulgaria, the Caucasus and Tien Shan. Winters in the Mediterranean region, Africa south to the Equator, and India' (Peters).

Jynx torquilla

1 *J. t. himalayana* (797a). 2 *J. t. torquilla* (796).
3 *J. t. chinensis* (797). 4 *J. t. japonica* (RE).

GENERAL HABITS, FOOD, VOICE and CALLS. As in 797a, q.v.

BREEDING. Extralimital.

MUSEUM DIAGNOSIS. For description of plumages and structure (also bionomics) see Witherby, 1938, 2: 292-6.

Differs from *J. t. chinensis* (797) in being paler, less brown above, with the dark markings on nape, back, and scapulars brownish rather than blackish. Below, paler on throat and upper breast, the spots and vermiculations on the underparts being finer, less coarse.

MEASUREMENTS

♂♂	83-91	14-17	19-20	61-71 mm
♀♀	83-91	—	—	— mm

Wing 30 ♂♂ (Sweden) 84-94 (av. 89) mm — Vaurie.

WOODPECKERS

171

habitats in winter, but apt to be overlooked due to its drab sparrow-like appearance and unobtrusive behaviour. A bird ringed in Saurashtra in October 1960 was recaptured in the same locality the following year almost to the date (Shivraj Kumar, JBNHS 58: 807). Though a member of the woodpecker family, feeds more on ground than on trees. Clings to upright stems and branches, where its coloration is remarkably obliterative, as well as perches crosswise like a true passerine. Picks ants etc. off branches and from crevices of bark, but does not 'drum' like woodpecker. Hops about on the ground with tail partially cocked, like Indian Robin, picking ants and crawling insects: frequently flushed in open scrubland while thus engaged. Flies up into a branch or bush when disturbed, soon descending again to resume feeding. Dipping flight, habit of twitching the wings upon alighting, and general behaviour very finch-like. When surprised within its nest-hole or handled, has a comical way of stretching neck and bill upwards, erecting forehead feathers, and screwing neck continuously from side to side like a clockwork toy, whence the name 'Wryneck'. This apparently an agonistic posture to deter would-be enemies: but the bird makes no sound nor any attempt to peck.

FOOD. Chiefly ants and their eggs and pupae. In an intensively cultivated area in Bihar, stomachs of 8 examples found crammed almost exclusively (up to 500 in a single stomach) with the ant *Phidole malini*, with a few examples of *Camponotus compressus* and the weevil *Myliocerus discolor*, picked up mostly in cotton fields (Mason & Lefroy, 1912).

VOICE and CALLS. Only occasionally heard in winter, more commonly in spring and summer: a shrill, quick-repeated and rather nasal *cheem, cheem, cheem* (4 or 5 times, at c. 3 per second) of a timbre between the notes of Common Myna and Goldenbacked Woodpecker. This usually the first indication of the bird's presence in a locality (SA). In summer (breeding?) 'a loud plaintive note of several syllables *ter-ter-ter-ter* repeated very quickly about 18 times, audible for a long distance — reminiscent of the distant call of an angry kestrel' (Whistler).

BREEDING. *Season.* (in Kashmir) chiefly May-June. *Nest.* a tiny natural hollow or slit in a willow, mulberry or chenar tree and the like at varying heights. The most favoured sites are evidently disused borings of the Brown-fronted Woodpecker with apertures small enough to exclude interloping mynas and starlings. Self-excavation of holes, as reported, needs confirmation. *Eggs.* 6 to 8, white, slightly glossed, oval, somewhat pointed at the small end. Average size of 13 Kashmir eggs 21.1 x 15.5 mm (BBO). Share of the sexes in incubation, and period, undetermined. Young fed largely on ants, ants' eggs and pupae dug out of the ground and conveyed in over-flowing beakfuls by both parents.

MUSEUM DIAGNOSIS. Differs from 796 and 797 in being more vermiculated on the lower breast, abdomen and flanks: the markings broader, less arrow-shaped, and tending to coalesce, giving the abdomen a barred rather than spotted appearance.

MEASUREMENTS

Wing 12 ♂♂ 81-90 (av. 86) mm — Vaurie.

Weight 20 ♂♀ (possibly mixed subspecies) 30-39 (av. 34) g — SA.

COLOURS OF BARE PARTS. Iris brown. Bill brownish flesh colour; gape yellowish cream; mouth pale pink. Legs and feet greyish leaf-green; claws dusky.

Plate 61, fig. 2

LOCAL NAMES. *Wiri* (Nepal); *Dangchim* (Lepcha); *Danja gadajis tirling* (Cachari).

SIZE. Sparrow —; length c. 10 cm (4 in.).

FIELD CHARACTERS. A diminutive woodpecker with short, soft, rounded black-and-white tail.

Male. Above, back and mantle bright yellow-olive; forecrown black-and-orange; a broad blackish olive band behind eye and down side of neck bordered above and below by conspicuous whitish bands; a dark moustachial stripe under the lower band. Below, yellowish white with bold black spots coalescing into bars on posterior flanks.

Female. Similar to male but with the whole crown yellow-olive, concolorous with back.

STATUS, DISTRIBUTION and HABITAT. Resident. The Himalayas from about Abbottabad and Murree in W. Pakistan (c. 73°E.) eastward through Kashmir, Himachal Pradesh, Garhwal, Kumaon, Nepal, Sikkim, northern Bengal

One of central pair of rectrices, x c. 1 (After Hartert)

173

(Darjeeling dist.) and Bhutan to Assam north and west of Brahmaputra R., and in the Khasi Hills: plains, foothills and up to c. 2000 m (recorded up to c. 3000 m in NW. Himalayas). Affects low jungle and tangled brushwood with bamboos, in moist-deciduous and semi-evergreen biotope. In the Himalayas and Assam habitat largely coincident with that of Rufous Piculet (800, 801).

GENERAL HABITS. Keeps singly or in pairs. Commoner than it appears to be, but liable to be overlooked amongst the restless itinerant hunting parties of tits, warblers, nuthatches and small tinelines, etc. with which it usually associates. May be picked out by its typical 'triangular' woodpecker shape and its habit of working as a detached outrider of the flock, chiefly on the end-twigs of trees and shrubs, frequently on stems of low bushes close to the ground. Creeps energetically along or in circles around thin branches like a nuthatch, clinging on the underside back to the ground, tapping persistently now and again in true woodpecker style — producing a surprisingly big noise for such a small bird. Also perches crosswise like a passerine, and has been observed to hover like a sunbird in front of a sprig to take a spider. In one phase of the courtship the male chases the female, scuttling forwards and 'in reverse' in little jerky spurts round and round a branch. Flight strong and direct with fewer of the typical woodpecker dips and undulations.

FOOD. Mainly ants and their eggs and pupae.

VOICE AND CALLS. A sharp *spit*, *spit* frequently repeated. A persistent mechanical drumming *br-r-r*, *br-r-r-r* with the bill on a bamboo stem or dead snag of a branch, repeated at regular intervals. Rather sonorous and remarkably loud and far-reaching for a bird of this size; given chiefly, but not only in the breeding season and serving to advertise the presence of individuals to one another.

BREEDING. Season, principally April and May. *Nest*, a hole drilled by the birds themselves in a hollow bamboo or rotten branch or stem of a small tree one to five metres up, often used for more than one year; entrance-hole barely 2.5 cm in diameter, chamber about 15 cm deep and 6 or 7 cm wide at the end. *Eggs*, 3 or 4, white, rather glossy, roundish ovals. Average size of 30 eggs 14.8 × 12 mm (Baker). Both sexes share in excavating the nest (?), incubation, and feeding the young. Period of incubation undetermined; presumed by Baker to be 11 days.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

Young (immature). A dull edition of the female. See Field Characters.

Differs from the eastern and S. Indian subspecies *malayorum* (799) in having the upper plumage bright golden yellow; underparts strongly washed with yellow and less heavily spotted with black.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	54-61	12-14	13-14	29-35 mm (BB, SDR, SA)

Weight 4 ♂ ♀ 10.5-12.5 g (Diesselhorst, SA).

COLOURS OF BARE PARTS. Iris brown or reddish brown. Bill dark slaty black or plumbeous, paler at tip. Legs and feet dull plumbeous.

WOODPECKERS

175

800. *Sasia ochracea ochracea* Hodgson

Sasia ochracea Hodgson, 1836, Jour. Asiat. Soc. Bengal 5: 778 (Nepal)

Baker, FBI No. 1419, Vol. 4: 95

Plate 61, fig. 5

LOCAL NAMES. *Sasya* (Nepal); *Chim*, *Chin pho* (Lepcha).

SIZE. Sparrow —; length c. 9 cm (3½ in.).

FIELD CHARACTERS. A diminutive, dumpy, stub-tailed bird, very unlike the conventional woodpecker.

Male. Deep rufous and olive overall, with rufescent golden forehead, a short broad white supercilium (above and behind eye), and stumpy black tail.

Female similar but lacking the yellow forehead, which is almost concolorous with the crown.

STATUS, DISTRIBUTION AND HABITAT. Resident; not uncommon, but unobtrusive and easily overlooked. The Himalayas from Garhwal eastward through Kumaon, Nepal, Sikkim, Bhutan, NEFA, and Assam in the Dibruigarh area: duns, foothills, and locally up to c. 2100 m. Affects mixed semi-evergreen and deciduous secondary scrub- and bamboo jungle.

GENERAL HABITS. Keeps singly or in pairs, frequently in marginal association with the quick-moving itinerant hunting parties of small insectivorous birds. Active and restless. Flits about in brushwood, clinging to and spiralling up bamboo culms and looping creeper stems etc. with quick jerky movements, busily tapping with its bill like a nuthatch or tit every now and again for minutes at a time, making an inordinately loud noise. Also perches crosswise on a twig like a passerine. Sometimes hops amongst the debris of decaying bamboo stems and mulch on the ground with its absurd little tail cocked up like a wren's. Has not been recorded 'drumming'.

FOOD. Insects: chiefly ants and their eggs and pupae.

VOICE AND CALLS. 'A querulous miniature of its larger brethren, uttered both in flight and while climbing' (Baker).

BREEDING. Season, not properly determined: eggs taken between May 25 and July 2. *Nest*, a tiny hole (c. 2.5 cm in diameter) drilled fairly low down in a decaying hollow bamboo, in mixed scrub- and bamboo jungle. *Eggs*, 3 or 4, white, rather glossy roundish ovals, indistinguishable from those of Speckled Piculet. Average size of 12 eggs 15.9 × 12.7 mm (Baker). Other facts of breeding biology unknown.

MUSEUM DIAGNOSIS. Differs from the Burmese population (801) in being much darker more olive above, with deep ferruginous underparts.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	52-55	12-15	14-15	22-24 mm (SA, SDR, BB)

Weight 1 ♂ 10 g (SA).

COLOURS OF BARE PARTS. Iris red; circumorbital skin crimson in ♂, pale magenta in ♀. Bill: upper mandible black, lower pale grey. Legs and feet yellowish brown.

(Kotagiri, Nilgiri Hills)

Baker, FBI No. 1417, 1418, Vol. 4: 94

LOCAL NAME. *Mārūmkotti* (Malayalam).

SIZE. Sparrow —; length c. 10 cm (4 in.).

FIELD CHARACTERS. As in 798. See Museum Diagnosis.

General effect and coloration reminiscent of Thickbilled Flowerpecker, *Dicaeum agile* (1892).

STATUS, DISTRIBUTION AND HABITAT. Resident. The Western Ghats complex (including Nilgiri, Palni and associated hills) from about Goa and Belgaum (c. 16°N.) south through western Mysore (Malnaad) and Kerala: Andhra (Eastern Ghats), eastern Madhya Pradesh (Bastar dist.), Orissa (hill tracts), southern Bengal (Khulna Sunderbans), East Pakistan (hill tracts), Mizo (?), Manipur, Nagaland, Assam east of Brahmaputra R., and eastern NEFA (Mishmi Hills): foothills and up to c. 2000 m. Affects moist-deciduous and semi-evergreen secondary jungle and mixed bamboo forest. In SW. India habitat coincident with that of Great Black (830) and Larger Goldenbacked (862) woodpeckers.

Extralimital. Eastern Burma, southern Shan States, Thailand, Malay Peninsula, Vietnam, Laos, Sumatra, Borneo (Peters).

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 798, q.v.

BREEDING. Season, in SW. India January to March; elsewhere evidently somewhat later — March–April. *Nest*, eggs and breeding biology as in the nominate subspecies.

MUSEUM DIAGNOSIS. Upperparts duller and paler than in *innominatus* (798); crown somewhat darker, with the dark centres to the feathers more pronounced. Underparts, excepting throat, rather more heavily spotted and with a paler yellow wash.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	57-62	11-12	12-14	30-35 mm (SA, HW, Koelz)

COLOURS OF BARE PARTS. As in 798.

Genus *SASIA* Hodgson

Sasia Hodgson, 1836, Jour. Asiat. Soc. Bengal 5: 778. Type, by original designation, *Sasia ochracea* Hodgson

Differs from *Picumnus* in having only three toes (first, or inner hind-toe wanting), and a naked circumorbital patch. Tail even shorter than in *Picumnus*; culmen slightly more rounded.

SASIA OCHRACEA Hodgson: RUFOUS PICULET

(Kohima, Naga Hills)

Baker, FBI Nos. 1420, 1421, Vol. 4: 96, 97

LOCAL NAME. *Dao jagadaiya kashiba gajao* (Cachari).

SIZE. Sparrow —; length c. 9 cm (3½ in.).

FIELD CHARACTERS. As in 800. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident; not uncommon, but unobtrusive and easily overlooked. Assam south of Brahmaputra R., Nagaland, Manipur, Mizo dist. and East Pakistan (hill tracts): plains level to c. 1700 m. Affects mixed semi-evergreen and deciduous secondary scrub- and bamboo jungle.

Extralimital. Burma, S. Shan States, N. Tenasserim, N. and E. Thailand, Laos and Vietnam.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 800, q.v. A sharp, high-pitched *trik* similar to the call of *Ceryx* or *Pnoepyga* (Heinrich).

BREEDING. Season, March to June. *Nest* and *eggs* (c/3 or 4) as in 800. Nest-holes usually drilled low down in decaying bamboos, occasionally in branches of small trees. Average size of 40 eggs 15.3 × 12.2 mm (Baker). Courtship display described as 'very pretty and quite typical of the family. The little female crouches against a bamboo or trunk of a tree and the little male then flutters on to the same a foot or two above her, at once running rapidly backward towards her; arrived where she is, he then drops a few feet and runs up to her, seems to skip over her and run up the bamboo, and then go through all the procedure again, perhaps once or twice, perhaps half a dozen times before anything further takes place. All the time the head and neck of both birds are twisted backwards and forwards, and volleys of little squeaks are uttered, growing louder and louder until the finale is reached' (Baker).

MUSEUM DIAGNOSIS. Differs from nominate *ochracea* (800) in being much paler and less olive above, with orange-rufous underparts (c. deep ferruginous).

MEASUREMENTS AND COLOURS OF BARE PARTS. As in 800.

LOCAL NAMES. *Chempān mārmākkōtti* (Malayalam); *Dūmbura kerellā* (Sinhala); *Mārmākkōtti*, *Thachchan kūrūvi* (Tamil).

SIZE. Myna ±; length c. 25 cm (10 in.).

FIELD CHARACTERS. A chestnut-rufous woodpecker, narrowly cross-barred with black on upperparts, wings and tail. Feathers of throat pale-edged producing a scaly or scalloped pattern. Male distinguished from female by a crescent-shaped crimson patch of feathers under the eye. See Museum Diagnosis.

Young (immature). More heavily barred than adult both above and below, the bars on the underparts crescentic in shape on breast and abdomen.

STATUS, DISTRIBUTION and HABITAT. Resident; locally common. From about the Tapi R. in Gujarat south through western Maharashtra, Mysore, western Tamil Nadu (also Shevaroy Hills), Kerala and Ceylon; wooded plains and foothills up to c. 1000 m. Affects secondary jungle mixed with bamboo, in moist-deciduous biotope.

GENERAL HABITS. Goes about in pairs and is usually met with in jungle abounding in carton nests of tree ants with which it is closely associated. Frequently seen hammering away and digging into such ants' nests, while

178

PICIFORMES

GENERAL HABITS, FOOD, VOICE and CALLS. As in 804, q.v.

BREEDING. Season, chiefly April to June. Nest, eggs and breeding biology as in the Southern subspecies (804).

MUSEUM DIAGNOSIS. The largest of the three Indian races. Upperparts paler, less bay than in the other two; head greyer. Sides of head, chin and throat much paler, the squamation on the last being in the nature of chestnut and buff streaks as in *phaeiceps* (803) v. dark chocolate and whitish scalloping in *jerdonii*.

x c. 1

STATUS, DISTRIBUTION and HABITAT. Resident; locally common. From Nepal (west-central ?) eastward through Sikkim, Bhutan, Assam, Nagaland, Manipur, and East Pakistan. West Bengal, Bihar, Orissa, eastern Madhya Pradesh (Balaghat and Bastar dists.) and south in northern Andhra to c. 18°N. (Anantgiri). Terai, duars, plains and foothills up to c. 1500 m; commoner below c. 700 m than above. Affects sal and secondary mixed forest with bamboo, in moist-deciduous biotope.

Extralimital. Extends through Burma (including the Shan States), and Thailand.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 804, q.v.

180

PICIFORMES

clinging to them or from an adjoining perch. Comes out after a bout of digging on to a neighbouring branch (sitting across it like a passerine) picking out the ants from its plumage and swallowing them. The head of the bird, abdomen and tail-tip are usually besmeared with a strong-smelling resin, often with numerous ants' heads sticking to the tail. The origin of this resin is not quite clear. Much given to drumming, but on the whole rather silent vocally.

FOOD. Mainly ants and their pupae, of which *Crematogaster* spp., *Phidola malinai* and *Oecophylla smaragdina* have been commonly identified. The first perhaps forms the staple food item; as many as 2600 *Crematogaster subnuda* have been counted in a single stomach (Mason & Lefroy, 1912). Occasionally takes fruit, especially wild figs (*Ficus*), and flower nectar (*Erythrina*, *Salmalia*); has been observed clinging to a smooth banana stem, puncturing it near the base of the leaves and sucking the sap.

VOICE and CALLS. A high-pitched nasal *keen*, *keen*, *keen* almost invariably repeated 3 times (rarely 4), very similar to one of the commoner notes of the Common Myna and of the same timbre.

Drums (evidently male only) frequently and regularly in the breeding season, sporadically and half-heartedly at other times. The drumming consists of a series of very rapid 'vibratory' hammering with the bill on a tree-trunk or bamboo to which the bird is clinging upright. It starts softly and works up to a reverberating crescendo of sound audible a quarter kilometre away. The bursts, of 10-12 strokes each, are repeated every 10 or 15 seconds. After each burst the drummer turns his head round purposefully to right and left as if expecting a response, and often gets it from another performer in the distance. Often drums at the same spot for over quarter of an hour, thereafter flying off to resume from elsewhere within its territory (?). The drumming is not interpolated with any vocal calls: it is given chiefly till the morning warms up, and again in the cooling afternoon until sunset. Flight undulating, typical of the woodpeckers — a few rapid wing-beats followed by a long dipping bound with wings closed to sides.

BREEDING. Season, principally February to end April; in Ceylon March to June. Nest, normally a hollow excavated in a 'live' oval-shaped carton nest of tree ants (*Crematogaster*, *Plagiolepis*, etc.) made of a blackish papiermâché-like substance commonly in trees 4 or 5 metres from the ground. Usually a lateral entrance-hole c. 5 cm in diameter gives access to the hollowed-out interior, leaving a wall about 25 mm thick all round the chamber. Only occasionally nests in tree-holes like a conventional woodpecker. Eggs, 2 or 3, white, unglazed, slightly longish ovals. Average size of 10 eggs 28.1 x 20.1 mm (Baker). Both sexes share in excavating the nest: share in incubation, period, and other details unknown. The eggs, incubating bird and chicks, even when newly hatched and naked, remain unmolested by the otherwise ferocious insects, the immunity being doubtless derived through the acrid 'anty' smell acquired by the birds and contents of the nest from physical contact with, and a diet of, the ants. This is a subject for closer investigation.

MUSEUM DIAGNOSIS. Distinguished from both *humei* and *phaeiceps* by the squamation on throat being dark chocolate and whitish (v. chestnut and buff), the squamation being more in the nature of scalloping than of longitudinal streaks. There is a

WOODPECKERS

181

slight decline in size from the northern parts of its range southward to Kerala and Ceylon.

D. Lower parts barred; a yellow nuchal spot..... <i>P. chlorolophus</i>	192

PICUS SQUAMATUS Vigors: SCALYBELLED GREEN WOODPECKER

Key to the Subspecies

Darker; under plumage feathers with broad dark brown edges..... <i>P. s. squamatus</i>
Much paler; edges of feathers of under plumage very narrow and pale..... <i>P. s. flavirostris</i>

WOODPECKERS

183

Female. Similar to male but somewhat duller and less green. Crimson of crown replaced by black, speckled with leaden grey.

Young (immature) like female, but with the breast feathers also squamated like the abdomen though less boldly.

STATUS, DISTRIBUTION AND HABITAT. Resident. Common and fairly abundant; subject to slight winter-summer altitudinal movement: Western Himalayas from Chitral and Gilgit through Kashmir, Baltistan, Punjab Salt Range, Himachal Pradesh, Garhwal and Kumaon to central Nepal (Langtang Valley, Manangbhot); between c. 1000 and 3300 m. Affects open evergreen mixed oak and pine hill forest and the neighbourhood of clearings; frequents orchards near Srinagar and in other valleys in winter.

Picus squamatus

1 *P. s. squamatus* (807). 2 *P. s. flavirostris* (806).

GENERAL HABITS. Typical of the woodpeckers. Keeps in pairs, normally seen clinging to trunks of trees (occasionally to rocks and cliffs), the stiff pointed tail pressed against the bark functioning as the third leg of a tripod. Works its way up in a series of jerky spurts, directly or in spirals—occasionally sliding back in reverse to re-investigate—tapping with the bill from time to time to stampede insects lurking in the crevices and locate hidden pupal galleries of wood-boring beetles. The long, worm-like barbed-tipped tongue enables the grubs to be skewered out of the holes and crannies. Commonly descends to the ground, hopping about rather uncomfortably to pick up ants and termites which form a considerable proportion of its diet. These tiny insects are picked up in the tips of the mandibles. Flight swift and undulating, consisting of 4 or 5 rapid noisy flaps followed by a long dipping glide or bound.

FOOD. Mainly ants and termites, and larvae and pupae of wood-boring beetles. Also berries, especially in winter.

182

PICIFORMES

806. *Picus squamatus flavirostris* (Menzbier)

Gecinys flavirostris Menzbier, 1886, Bull. Soc. Imp. Nat. Moscou 62 (1): 439

(Murghab, Transcaspiya)

Baker, FBI No. 1338, Vol. 4: 8

LOCAL NAMES. None recorded.

SIZE. Pigeon +; length c. 35 cm (14 in.).

FIELD CHARACTERS. As in 807. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. West Pakistan in the wooded NE. Baluchistan hills between c. 1300 and 3300 m (Zhob Valley, Ziarat, Quetta, and in Chagai dist.), in juniper, oak and poplar forest.

Extralimital. Transcaspiya to Afghanistan.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 807, q.v.

BREEDING. Favourite nesting localities in Chagai dist., Baluchistan, reported as Hazarganj Reserved Forest on Chiltan, Mari Chak Reserved Forest, Barshor and Surkhab valleys, and Kaisar jungle near Nushki 'which appears to be the western limit of this race in Baluchistan' (A. F. P. Christison MS.). Season curiously enough not mentioned though he found nests in pistachio, chilghuza, wild apricot, mulberry, juniper, willow, and even tamarisk scrub. In the last case the nest was '5 ft below ground level where the root was exposed in a nullah bank 7 ft from the bed'. No clutch size, description or measurements of eggs given!

MUSEUM DIAGNOSIS. Differs from nominate *squamatus* (807) in being much paler everywhere, with the pale markings broader and the dark markings narrower—especially the brown squamations on the underparts. Lower plumage much suffused with yellow.

MEASUREMENTS AND COLOURS OF BARE PARTS as in 807.

Plate 62, fig. 6

LOCAL NAMES. *Tuktola* (Himachal Pradesh); *Koel makots* (Kashmir).

SIZE. Pigeon +; length c. 35 cm (14 in.).

FIELD CHARACTERS. A medium-sized green woodpecker with pale underparts boldly scalloped with black.

Male. Above, crown and crest crimson; a broad whitish supercilium bordered above and below with black lines; whitish cheeks and a prominent black moustachial streak. Upper plumage dull grass-green with a bright yellow rump. Below, throat and breast pale greyish; rest of underparts greenish white with scale-like black markings.

¹Synopsis No. 805, *Picus viridis bampurensis* (Zarudny), expunged as extralimital.

184

PICIFORMES

VOICE AND CALLS. A wild, ringing, rather melodious double-noted *klee-gu* or *pea-cock*; occasionally a single long-drawn nasal *cheent* or *peer* repeated every 10 or 15 seconds for many minutes continuously. In addition to these vocal sounds, produces a loud mechanical drumming by very rapid, 'vibratory' hammering with its bill on a selected 'sounding board' on a dead tree-trunk or branch. The male drums chiefly in the breeding season, evidently to advertise his territory.

BREEDING. Season, March to June, principally April and May. Nest, a circular hole about 6 cm across usually chiselled out in a large tree-trunk 2 to 6 metres from the ground—sometimes up to 15 metres or more—turning down into a vertical shaft 15 to 30 cm deep ending in a widened egg-chamber. Eggs, 5 or 6, white, broad ovals. Average size of 50 eggs 31 × 22.6 mm (Baker). Share of the sexes in excavation of nest-hole and incubation, and incubation period, unrecorded.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit. Above, darker than the Transcaspiya subspecies (806). Below, greyish white, less suffused with yellow, and with broader more prominent blackish scaly markings.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂♀	155-172	27-33	c. 27	127-136 mm (Baker)

Weight 1 ♂ 185 g; 1 ♀ 170 g (Paludan).

COLOURS OF BARE PARTS. Iris in two rings, the inner red or crimson-pink, the outer paler pink. Bill horny yellow: dark at tip, more yellow on base of lower mandible. Legs dull yellowish green or greenish plumbeous.

808. Little Scalybelled Green Woodpecker. *Picus myrmecophoneus* Stresemann

Picus myrmecophoneus Stresemann, 1920, Verh. Orn. Ges. Bayern 14: 289 (Himalaya and Central India). New name for *Picus striolatus* Blyth, preoccupied

Brachylophus xanthopygerus 'Hodgs.' = J. E. & G. R. Gray, 1846, Cat. Spec. Mamm. Bds. Nepal and Tibet: 117 ex Hodgson in Gray, 1844, Zool. Misc. nomen nudum

quoted in synonymy of *Gecinys striolatus* (Blyth), preoccupied

Plate 62, fig. 7

LOCAL NAMES. (For all woodpeckers) *Mārāmlottī* (Malayalam); *Kerellā* (Sinhala); *Mārāmlottī*, *Thachcher kūrī* (Tamil).

SIZE. Myna +; length c. 29 cm (11½ in.).

FIELD CHARACTERS. A medium-sized typical woodpecker with stout chisel-shaped bill and stiff, pointed wedge-shaped tail.

¹ Biswas (JENHS 58: 124) considers this a valid race.

WOODPECKERS

185

Male. Above, grass-green, with bright yellow rump; tail greenish brown, faintly and imperfectly barred with whitish. Crown and crest crimson; an orange-and-black patch on nape; a prominent white supercilium from eye backwards, bordered above by a black line; ear-coverts pale grey-brown; cheeks greyish white streaked with black. Below, pale greenish fulvous boldly scalloped or squamated with black; chin and throat fulvous-grey streaked with white.

Female similar but with crown and crest black instead of crimson.

x c. 1

STATUS, DISTRIBUTION AND HABITAT. Resident; fairly common locally, more or less throughout the Peninsula and Assam, east of a line from about Ambala to Mt. Abu; north to the Himalayan terai and foothills (up to c. 1700 m — rarely) from Punjab eastward through U.P., Nepal, Sikkim (?) and Bhutan (?). Also Ceylon (Dry zone) and East Pakistan. Semi-evergreen and moist-deciduous biotope. Affects sal, and mixed bamboo and deciduous forest, keeping to open secondary jungle, teak and other forest plantations, etc. (in S. India very partial to rubber plantations); from plains level to c. 1800 m in the peninsular and Ceylon hills.

Extralimital. Burma, SW. Thailand, Cambodia and South Vietnam.

GENERAL HABITS. Typical woodpecker; very similar in habits to 807, q.v. Perhaps feeds more commonly on the ground than most other woodpeckers.

FOOD. Largely ants and termites taken on the ground; also pecks at dry cattle dung for beetle larvae etc.; flower nectar when available (e.g. *Erythrina*, *Salmalia*); has been observed bibbing juice from a date palm tapped for toddy.

VOICE AND CALLS. Normally rather silent. A single-syllabled 'mild falsetto note' (Nichols), like that of 807, but seldom uttered. Also the characteristic mechanical drumming with the bill on a tree-trunk or bough.

BREEDING. Season, overall January to June, varying with locality — chiefly March, April and May on the mainland; April to September in Ceylon. Nest, a circular hole c. 5 cm across, cut in the bole of a tree turning downward into a vertical shaft up to c. 50 cm deep and ending in an expanded chamber. Nest-holes normally between 4 and 8 metres from the ground. Eggs, 3 to 5, pure white, broad ovals laid on the bare wood at the bottom of the shaft. Average size of 30 eggs 26.2 x 20.1 mm (Baker). Both sexes share in excavating the nest, incubation and feeding the young. Period unrecorded.

WOODPECKERS

187

STATUS, DISTRIBUTION AND HABITAT. Resident: common. The western Himalayas from Punjab (Murree) eastward through Himachal Pradesh, Garhwal and Kumaon to central Nepal (where it intergrades with 810). From the terai up to c. 2400 m, in moist subtropical and temperate forest biotope.

The species, in many geographical races, is widely distributed in Europe and Asia.

Picus canus

■ Breeding range

- 1 *P. c. sanguineus* (809).
- 2 *P. c. hessei* (810).
- 3 *P. c. sordidior* (811).
- 4 Other races (about 15) extralimital.

GENERAL HABITS. Typical of the woodpeckers and very similar to those of 807, q.v.

FOOD. Mainly ants and termites often taken on the ground, the termites being hacked out of ant-hills; also larvae and pupae of wood-boring beetles. Berries chiefly in winter; flower nectar as supplementary food in season.

VOICE AND CALLS. A nutty, high-pitched, rather musical peek, peek, peek, repeated in runs almost invariably of 4 or 5, fading out on the last note. Male drums frequently in the breeding season, commencing well before sunrise. Rattle loud but soft in tone — reminiscent of the dampened ring of an automatic telephone — in bursts two to three seconds long each, repeated every 10 to 15 (or 20) seconds. The drumming is punctuated more or less regularly from time to time by the vocal calls. The performance is given day after day from the same 'sounding board' near the top of a bare tree, and is sometimes kept up for over an hour in the early morning. Also has the typical chattering alarm cry of the family.

186

PICIFORMES

MUSEUM DIAGNOSIS. There is great individual variation in the size of bill and tail, partly due to wear, and also in plumage coloration. The latter is largely the result of abrasion which produces a peculiar silvery frosted appearance on the back. There is no spring moult in this species.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	124-138 (once 142)	28-38	22-26	76-97 mm
♀♀	124-134	25-35	21-26	78-93 mm (HW, SA)

Weight 1 ♂ 111 g (GD); 1 ♀ 98 g (SDR).

COLOURS OF BARE PARTS. Iris pinkish white with inner ring of brownish red. Bill horny slate, pale yellow on sides of lower mandible excepting tip; mouth greyish pink. Legs and feet greyish sage-green; claws horny.

PICUS CANUS Gmelin: BLACKNAPED GREEN WOODPECKER
Key to the Subspecies

A	Underparts green	Page
a	Above darker and more green; no bronze or golden sheen; below darker and greener.....	<i>P. c. sanguineus</i> 186
b	Above lighter with a strong bronze sheen; below more tinged with yellow.....	<i>P. c. hessei</i> 188
B	Underparts grey; rectrices very pale, no black.....	<i>P. c. sordidior</i> 189

809. *Picus canus sanguineus* Baker

Picus canus sanguineus Baker, 1926, Bull. Brit. Orn. Cl. 46: 70. New name for *Picus occipitalis* Vigors, preoccupied (Himalayas, Simla-Almora dist.) Baker, FBI No. 1343, Vol. 4: 13

Plate 62, fig. 5

LOCAL NAMES. None recorded.

SIZE. Pigeon ±; length c. 32 cm (12½ in.).

FIELD CHARACTERS. A largish green woodpecker with the typical stiff wedge-shaped tail and stout chisel-pointed bill.

Male. Above, dark green, tinged on the rump with bright yellow. Wing-quills dark brown with white bars; tail black, imperfectly barred paler. Forehead and forecrown crimson; hindcrown, occipital crest and nape black. Sides of head, including ear-coverts and supercilium grey, the last bordered above by a black line. Below, chin and throat greyish ashy, with a black malar stripe from lower mandible down each side. Rest of underparts dull yellowish olive-green, greyer on abdomen.

Female, like male but with whole forehead, crown and nape black, streaked with grey.

Young (immature), like female but duller, the tail-feathers more definitely barred. Underparts also more or less barred with whitish.

188

PICIFORMES

BREEDING. Season, principally May and June. Nest, the normal circular woodpecker cutting in a tree-trunk between 2 and 8 metres up, often under one metre. Recorded as low as 15 cm with the nest-chamber — in this case a natural hollow — actually below ground level. Eggs, 4 or 5, pure white broad ovals. Average size of 28 eggs 29.5 x 22.8 mm (Baker). Both sexes share in excavating the hole and feeding the young; evidently also in incubation. Period of incubation undetermined.

MUSEUM DIAGNOSIS. Differs from the east Himalayan *P. c. hessei* (810) in being larger and a purer green in coloration, less yellowish or bronze; it is also more heavily marked on the occiput. For subspecific determination only fresh-plumaged birds (after the complete post-nuptial moult) are useful since in worn dress abrasion gives a greyish cast to the feathers which is apt to be misleading. First-year birds are readily identified by the long first primary being rounded at the tip.

MEASUREMENTS

	Wing	Bill (from skull)	Tail
Birds from Western Himalayas & Nepal:			
♂♂	157-165	46-49	— mm
(av. 160.6)*			(Greenway)†

Not in Baker, FBI

LOCAL NAMES. None recorded.

SIZE. Pigeon ±; length c. 32 cm (12½ in.).

FIELD CHARACTERS. As of 809. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. 'Very common in the Tsangpo Valley below Lilung' (Ludlow, 1944, *Ibis*: 368) in southeastern Tibet adjoining the Siang and Luhit Frontier Divisions of NEFA, and may occur within our limits. Has been collected between c. 2900 and 3550 m altitude. Affects fairly open conifer and deciduous forest.

Extralimital. Western China in provinces of Kansu and Sikang (Peters).

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 809, q.v. Feeds much on the ground, taking fruits and berries as well as insects. Some of the specimens collected by Ludlow had been feeding on the fruits of an *Actinidia* shrub and their intestines were dyed indigo-blue as a result.

BREEDING. Unrecorded.

WOODPECKERS

191

FIELD CHARACTERS. A largish yellow-green woodpecker with rufous-banded dark brown wings and a conspicuous golden yellow nuchal crest, sometimes erected fanwise under excitement. Tail black, unbarred; underparts olive-grey.

Male has the chin and throat bright lemon yellow; foreneck rich brown streaked with white.

Female similar to male but with the chin and throat rufous brown instead of yellow.

STATUS, DISTRIBUTION AND HABITAT. Resident. Nepal, Sikkim, Bhutan, NEFA, Assam, Nagaland, Manipur, Mizo and Bangladesh (hill tracts). West Bengal, Bihar and Orissa (Simlipal Hills). Visakhapatnam dist., E. Ghats (JBNS 73: 394). From plains level to c. 2400 m in the Himalayas locally; preferential zone between c. 700 and 1500 metres. Affects open mixed evergreen and deciduous forest; partial to edge of cultivation clearings in foothills country.

Extralimital. Burma and southern Shan States. Widely distributed in other races in SE. Asia.

GENERAL HABITS. Keeps in separated pairs or scattered family parties of 4 or 5, often in close association with racket-tailed and other drongos with no ulterior motive apparent on either side! Feeds a great deal on the ground and rarely high up in trees.

FOOD. Ants, termites and grubs and wood-boring beetles, e.g. *Haplo-cerambyx spinicornis*, a destructive borer of the sal tree (*Shorea robusta*).

VOICE AND CALLS. 'A fairly loud, plaintive pee-ü . . . pee-ü (high/falling)'—Lister. A single metallic chēnk; when disturbed and flying off a rich 'laugh' rather like that of the Great Black Woodpecker (830) but less loud and more musical (SA).

BREEDING. Season, March to May. Nest, the usual shaft inside the bole of a tree with a round lateral entrance-hole 7 or 8 cm across, cut at heights of 3 to 5 or 6 metres from the ground. Eggs, 3 or 4, white, broad ovals. Average size of 40 eggs 28.8 × 22.2 mm (Baker). Both sexes share in excavating the hole, incubation, and feeding the young. Incubation period undetermined. Courtship, described by Baker, as follows: Birds of a pair continually chase one another with a little squeaking cry, finally alighting on a tree. Female crouches [on a branch ?] close against the bark. Male approaches her backwards, 'his head thrown right over his rump with beak held up and crest very widely expanded'. After getting within a few inches of her he sidles across to the other side and repeats the same action, the female squeaking and shivering with excitement during the entire performance. After a few repetitions of this manoeuvre copulation takes place. Details not very clear and needing amplification.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

'Juvenile male like adult above but the crest paler yellow; gular streak pale yellow; chin and throat white spotted with black; rest of underparts as adult but belly greyer' (Ticehurst).

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂♂	163-177	40-45	27-32	114-127 mm

Smaller; a yellowish gloss on the green of the upperparts *P. f. flavinucha*
 Much larger; no yellowish gloss on upperparts *P. f. kumaonensis*

812. *Picus flavinucha kumaonensis* (Koelz)

Chrysophlegma flavinucha kumaonensis Koelz, 1950, Amer. Mus. Novit., No. 1452: 4 (Kathgodam, Naini Tal dist., U.P.)

Baker, FBI No. 1353 (part), Vol. 4: 23

LOCAL NAMES. None recorded.

SIZE. Pigeon ±; length c. 33 cm (13 in.).

FIELD CHARACTERS. As of 813. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident. Garhwal and Kumaon in Uttar Pradesh, from about Dehra Dun to western Nepal (possibly): foothills and up to c. 1700 m. Affects sal and oak forest.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 813, q.v. In common with several other woodpecker species has the curious habit of digging parallel rows of small shallow holes or 'craters' round the stems of smooth-barked trees, like the American Sapsuckers (*Sphyrapicus* spp.). See A. E. Osmaston, JBNHS 24: 363-6.

BREEDING. Season, nest, eggs, etc. as in the nominate race.

MUSEUM DIAGNOSIS. Differs from *flavinucha* (813) in lacking the yellowish flush in the green of the upperparts and having the rufous bars on the primaries much wider. Is also larger in size: Wing over 180 mm; tail over 131 mm (Biswas).

COLOURS OF BARE PARTS. As in 813.

Picus chlorolophus simlae Meinertzhagen, 1924, Bull. Brit. Orn. Cl. 44: 54 (Dehra Dun)

Baker, FBI No. 1347, Vol. 4: 18

LOCAL NAMES. None recorded.

SIZE. Myna +; length c. 27 cm (10½ in.).

FIELD CHARACTERS. As of 815. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident. The lower Himalayas from Punjab (Dharmasala) through Himachal Pradesh, Garhwal, Kumaon and Nepal to an arbitrary boundary (the Arun Valley) at c. 87°E. long. Intergrades with *chlorolophus* over a considerable area from eastern Kumaon to east-central Nepal. Terai, bhabar and foothills, locally to c. 2100 m. Affects evergreen and moist-deciduous jungle.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 815, q.v.

BREEDING. Season, nest, eggs, etc. as in *chlorolophus*. Average of 4 eggs taken near Naini Tal 25.5 × 19.15 mm (Baker).

MUSEUM DIAGNOSIS. Like nominate *chlorolophus* but somewhat larger and with the nuchal crest usually a paler lemon-yellow r. orange-yellow. But the differences in size and colour between the West Himalayan and East Himalayan populations follow a continuous cline, hence the need for an arbitrary boundary as above.

MEASUREMENTS

815. *Picus chlorolophus chlorolophus* Vieillot

Picus chlorolophus Vieillot, 1818, Nouv. Dict. d'Hist. Nat. 26: 78 (Bengal)

Baker, FBI No. 1346, Vol. 4: 17

Plate 62, fig. 2

LOCAL NAMES. None recorded.

SIZE. Myna +; length c. 27 cm (10½ in.).

FIELD CHARACTERS. A medium-sized yellowish green woodpecker with a golden yellow nuchal crest.

Male. Above, forehead, supercilia (continued behind to meet at nape) and a moustachial streak crimson; crown olive-green; nuchal crest golden yellow. Upper plumage bright yellowish green; wing-quills largely green and maroon-red. Tail brownish black with the central feathers edged bronze-green. Below, chin and throat brown, barred with whitish; breast olive-brown; rest of underparts barred brown and white.

Female. Similar to male but no crimson on forehead or malar stripe; crimson restricted to a short broad line from behind the eye to nape.

Young (immature) dull coloured above without any crimson on head. Underparts barred olive and white throughout.

STATUS, DISTRIBUTION and HABITAT. Resident. The lower Himalayas from about the Arun Valley in Nepal (c. 87°E.) eastward through Sikkim, Bhutan and NEFA. Assam, Nagaland, Manipur, Mizo, East Pakistan (hill tracts), lower Bengal, Bihar (Lohardaga). Terai, duars and foothills; locally to c. 2000 m. Affects mixed deciduous and evergreen secondary jungle.

Extralimital. Northern Burma and northern Shan States.

GENERAL HABITS. Typical woodpecker. Usually keeps in pairs, often in association with other woodpecker species or as a member of the itinerant mixed hunting parties of drongos, minivets, flycatchers, babblers and other insectivorous birds in forest. Commonly descends to the ground to pick ants etc.

FOOD. Insects, chiefly ants and termites; larvae and pupae of wood-boring and dung beetles. Berries as secondary food.

VOICE and CALLS. Advertising call (?) a plaintive, rather mournful-sounding, nasal single note *cheenk*, lasting c. ½ to 1 second—reminiscent of call of Black Bulbul—repeated monotonously every 15 to 30 seconds, often for 10 minutes or more at a stretch, while the bird is clinging motionless to a bare branch at the top of a forest tree. At each call the bill is raised to an angle of c. 45°, and head turned from side to side as if expecting a response, and yellow nape fluffed out into prominence. This call is given by both sexes. Other calls have been described as 'a most peculiar trill of 5 or more ascending notes, mistakable for some kind of cuckoo's', and a loud *quaaa* at intervals (Desirée Proud). Drums on wood in addition to the vocalizations.

BREEDING. Season, April–May. Nest, the usual woodpecker hole c. 5 cm in diameter in a dead or decaying tree-trunk, turned down into a vertical shaft up to 30 cm or more in depth and ending in a widened egg-chamber; no lining. The holes are often under 2 or 3 metres from the ground, but may be as high as 15 or 20. Eggs, 3 to 5, white, broad ovals. Average size of 50 eggs 24.3 × 19.0 mm (Baker). Both sexes share in excavating the hole, incubation, and feeding the young; incubation period undetermined.

WOODPECKERS

195

MUSEUM DIAGNOSIS. Differs from nominate *chlorolophus* in being smaller and much darker green above. Breast more or less spotted with white in all but the oldest birds. Extent of crimson on head much greater in both sexes; yellow on nuchal crest less in extent and much paler.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	120–128	26–32	20–24	78–89 mm
♀♀	119–128	26–30	20–23	77–84 mm

(SA, HW, Koelz)

Weight 4 ♂♂ 57–74 g; 3 ♀♀ 62–70 g (SA).

COLOURS OF BARE PARTS. Iris crimson. Bill horny brown or brownish black, yellow at sides of base, especially of lower mandible; mouth pink. Legs and feet greyish or dusky olive-green; claws horny.

817. *Picus chlorolophus wellsi* Meinertzhagen

Picus chlorolophus wellsi Meinertzhagen, 1924, Bull. Brit. Orn. Cl. 44: 56 (Ceylon)

Baker, FBI No. 1350, Vol. 4: 20

LOCAL NAMES. *Kondī kōhā kerellā* (Sinhala); *Mārāmkottī*, *Thachchan kūrēvī* (Tamil).

SIZE. Myna ±; length c. 25 cm (10 in.).

FIELD CHARACTERS. As of 815. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Endemic in Ceylon. Well distributed, in small numbers, throughout the low-country Wet zone (commonest in the foothills), and in some areas of the adjoining Dry zone; in the hills to c. 1800 m.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 815 and other Indian subspecies, 'Its call is a loud, harsh scream *queeter*, very reminiscent of one of the notes of the Indian Pitta' (Henry).

BREEDING. Season, February to July, chiefly March and April as in S. India. Nest and eggs as in *chlorigaster*, the latter approximately same size.

MUSEUM DIAGNOSIS. Differs from South Indian *chlorigaster* in being slightly smaller and with the upperparts a darker tinge of green, lacking most of the golden bronze sheen on the wings.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail

COLOURS OF BARE PARTS. As in 816.

Genus *DINOPIUM* Rafinesque

Dinopium Rafinesque, 1814, Principes Fondamentaux de Somnologie: 2 of cover. Type, by monotypy, *Dinopium (Picoidea) erythraestus* Rafinesque based on 'le picolide à dos rouge' = *Picus javanensis* Ljungh

194

PICIFORMES

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit. Differs from West Himalayan *simlae* in averaging somewhat smaller with the nuchal crest bright orange-yellow r. pale lemon-yellow.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂♀	126–142	21–28	c. 22–23	74–94 mm (Baker)

COLOURS OF BARE PARTS. Iris brownish crimson; bare skin round eye slaty plumbeous. Bill: upper mandible and tip of lower horny brown; upper mandible at gape, and basal portion of lower mandible, pale green. Legs and feet greenish plumbeous; claws brown.

816. *Picus chlorolophus chlorigaster* Jerdon

Picus chlorigaster Jerdon, 1844, Madras Jour. Lit. Sci. 13 (2): 139 (Southern India)

Baker, FBI No. 1349, Vol. 4: 19

Plate 62, fig. 3

LOCAL NAME. *Mārāmkottī* (Malayalam).

SIZE. Myna +; length c. 27 cm (10½ in.).

FIELD CHARACTERS. As of 815. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident. The Sahyadri or Western Ghats complex from the Nabhada river (W. Khandesh, Surat Dangs) south to Kerala, including the Nilgiris, Palnis and associated hills in western Mysore (Malnaad). Extends east to the Shevaroy and Nallamalai hills, and thence northward in the Eastern Ghats to northern Andhra (Anantgiri, Lamasinghi) and Orissa (Mayurbhanj), in appropriate semi-evergreen and moist-deciduous biotope. From plains level to c. 1800 m; commoner in the foothills. Affects secondary jungle and mixed teak and bamboo forest. Partial to rubber and coffee plantations.

GENERAL HABITS. As in the other races, cf. 815.

FOOD. Ants and grubs; occasionally berries. Stomachs examined in a forest plantation area contained predominantly adults and larvae of *Cremastogaster* sp. (Formicidae), and larvae of *Hepalia machaeralis* (Pyralidae), a harmful defoliator of teak (*Tectona grandis*).

VOICE and CALLS. Usually silent on the wing. A single sharp mournful note *cheenk* or *cheek* as in 815. One described by Betts as 'a single sharp *chak*' is possibly a variant rendering of the same.

BREEDING. Season, overall January to May, chiefly March and April. Nest, the usual woodpecker hole excavated by the birds in the trunk or vertical branch of a forest tree, between about 5 and 7 metres from the ground. Frequently bored under one of the large plate-shaped fungi that project like brackets from the trunks of dead trees in damp localities. Often the entrance-hole is quite low down and hidden under the porch-like projection. Eggs, normally 2, exceptionally 3, white, blunt ovals. Average size of 12 eggs 25.8 × 18.8 mm (Baker). Breeding biology as in 815. Period of incubation undetermined.

196

PICIFORMES

Bill about same length as head; culmen slightly curved; nasal ridge not much developed, close to culmen; nostrils exposed. Hallux or inner hind-toe very small or absent; third and fourth toes about equal in length. Wings and tail proportionately longer than in *Micropternus*; outer tail-feathers longer than upper tail-coverts. A red occipital crest in both sexes; in male crown also red, in female black spotted with white.

b Back lemon-yellow	<i>D. b. dilutum</i> 196
2 Throat spotted black and white	
c Back orange-yellow	<i>D. b. puncticollis</i> 199
d Back golden olive-yellow	<i>D. b. lehmanni</i> 199
e Back darker, duller with a more olive wash; underparts creamy buff rather than white	<i>D. b. jeffernisi</i> 200
f Back mostly red	<i>D. b. psarodes</i> 201

818. *Dinopium benghalense dilutum* (Blyth)

Br. (achypternus) aurantius var. *Br. (achypternus) dilutus* Blyth, 1849, Cat. Bds.

Mus. Asiat. Soc.: 56 (Sind)

Brachypternus benghalensis girensis Koelz, 1954, Contrib. Inst. Regional Exploration, No. 1: 23 (Sasan, Junagadh)

Baker, FBI No. 1396, Vol. 4: 69

LOCAL NAME. *Drakhan* (= carpenter, Sind).

SIZE. Myna +; length c. 29 cm (11½ in.).

FIELD CHARACTERS. As of 819. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident; common but local. West Pakistan in Baluchistan, Sind, NW. frontier districts and southwest Punjab, possibly east to about Ferozepore (c. 74°E.); also Mt Abu and parts of W. Rajasthan; intergrading with adjoining races. Affects dry deciduous and thorn forest; partial to avenues of sheesham and babool trees, and date

The subspecific differences in this woodpecker follow a continuous cline. Moreover, the birds are subject to considerable individual variation in respect of the features upon which subspecific diagnosis is based. Therefore boundaries are difficult to assign, and in many intergrading areas only a certain percentage of extreme cases can be definitely identified.

WOODPECKERS

197

groves along roads and canals, in and around villages, and urban gardens and compounds.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 819, q.v.

BREEDING. *Season*, chiefly March and April. *Nest, eggs* and breeding biology as in 819 and other races. Old gnarled tamarisks and babool and sheesham trees are favoured for nest sites.

MUSEUM DIAGNOSIS. Crest very long. Differs, sex for sex, from nominate *benghalense* (819) in having the upperparts a much paler yellow with obsolete white spotting and indistinct dark flecking to the feathers; shoulders black with conspicuous white spotting; rump black. White of underparts purer and more extensive on chin, throat and foreneck, which are streaked with black.

MEASUREMENTS

	Wing	Bill (from feathers)
♂ ♀	142-147	28-37 mm (Baker)

COLOURS OF BARE PARTS. As in 819.

Baker, FBI No. 1394, Vol. 4: 67

LOCAL NAMES. All woodpeckers *Kāphāra* (Hindi); *Khidree* (Bastar, M.P.); *Sona kaktola* (M.P., Saugor); *Vādrāngi pitta* (Telugu).

SIZE. Myna +; length c. 29 cm (11½ in.).

FIELD CHARACTERS. Male. *Above*, crown and occipital crest crimson; upper plumage chiefly golden yellow and black. *Below*, white streaked with black, more boldly on breast. Chin, throat, and sides of head black, finely streaked and stippled with white.

Female similar to male but with forecrown black, stippled with white like the throat, and only the occipital crest crimson.

Young (immature) like female but duller and browner, and without the white stippling on crown or forehead.

STATUS, DISTRIBUTION and HABITAT. Resident; the commonest and most widely distributed woodpecker in the subcontinent as a whole. Punjab, Uttar Pradesh, Nepal lowlands, Bihar, W. Bengal, Assam, Manipur (?), East Pakistan, Orissa, northern Andhra (south to about Godavari river), Madhya Pradesh, Rajasthan, Gujarat and northern Maharashtra. Intergrades with *dilatatum* in Punjab and with *puncticollis* around its southern limits (see footnote, p. 196). Plains, foothills and up to c. 1000 m (c. 1700 m — Dharmasala) in dry- and moist-deciduous biotope. Affects every type of wooded country: light forest, forest plantations, groves of mango, palmyra (*Borassus*) palms and other trees about villages and cultivation, urban compounds, roadside avenues, etc.

WOODPECKERS

199

No consistent size difference in the sexes.

COLOURS OF BARE PARTS. Iris reddish brown; circumorbital skin sage green. Bill horny black; mouth slaty pink or greyish pink. Legs and feet greyish leaf-green; claws slaty.

820. *Dinopium benghalense puncticollis* (Malherbe)

Picus (Brachypternopicus) puncticollis Malherbe, 1845, Rev. Zool.: 404

(India = slopes of the Nilgiri Hills)

Baker, FBI No. 1395, Vol. 4: 69

LOCAL NAMES. *Sōn pāthi nūlar* (Marathi). Woodpeckers in general: *Mārāmbkōtti*, *Tachchan kūrūri*, *Mānu potūkū* (Tamil); *Vādrāngi pitta* (Telugu).

SIZE. Myna +; length c. 29 cm (11½ in.).

FIELD CHARACTERS. As of 819. See Museum Diagnosis.

Distinguished from the very similar Threethroated Goldenback (825), especially in flight, by its black lower back and rump v. crimson.

STATUS, DISTRIBUTION and HABITAT. Resident; common. Peninsular India south of the range of 819 (excluding Kerala), north to about Godavari R. in the east and Rajasthan in the west (but see footnote, p. 196). Affects dry- and moist-deciduous biotope, plains and hills to c. 1200 m — light forest, roadside avenues, mango topos around villages and cultivation, wooded urban gardens and compounds, coconut, date and palmyra groves, etc.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 819, q.v.

BREEDING. *Season*, chiefly March–April. *Nest, eggs* (c/3) and breeding biology as in the nominate subspecies.

MUSEUM DIAGNOSIS. Upperparts golden yellow, intermediate between *dilatatum* and *benghalense*; rump black; shoulders partly black with conspicuous creamy white spotting; chin, throat and breast black, with small white triangular spots; white of lower plumage pale creamy white.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
9 ♂♂	138-146	35-41	24-28	82-89 mm
11 ♀♀	137-146	37-40	25-26	80-92 mm

(Jagalbed, Bombay State)

Baker, FBI No. 1395 (part), Vol. 4: 69

LOCAL NAMES. All woodpeckers: *Mārāmbkōtti* (Malayalam).

SIZE. Myna +; length c. 29 cm (11½ in.).

198

PICIFORMES

GENERAL HABITS. Typical of the woodpeckers. Keeps in pairs or family parties, frequently with the mixed hunting associations of various insectivorous species, the woodpeckers following one another from tree to tree and clinging vertically with an upward glide to the trunks and boughs. Creeps up in short jerky spurts, directly or in spirals, tapping spasmodically with the bill to stampede lurking insects or locate hidden pupal galleries of wood-boring beetles. Will occasionally slide back 'in reverse gear' to re-investigate some promising crevice it has missed. Flight undulating, swift and noisy, consisting of a few rapid flaps followed by a long dipping bound with wings pressed to the sides; usually accompanied by a shrill, chattering 'laugh'. Commonly descends to the ground and hops about picking up ants and crawling insects.

FOOD. Insects and larvae, predominantly ants, picked off tree-trunks and boughs, and on the ground. Fruits and berries: has been observed clinging to a half-ripe mango on a tree, digging into the flesh and swallowing morsels. Also takes flower nectar regularly — *Erythrina*, *Salmaia*, *Acrocarpus*, *Grevillea* recorded. Among stomach contents analysed from an intensively cultivated area in Bihar the following insects identified in quantity: ants (Formicidae — *Crematogaster subnuda*, *Camponotus compressus*, *Oecophylla smaragdina*, *Phidole malinsi* (?), *Meranoplus bicolor*, *Myrmecocystus setipes*); weevils (Curculionidae — *Myllocerus discolor*, *Aslycus lateralis*), beetles (Tenebrionidae — *Mesomorpha villiger*, *Derospharus rugicollis*), geometrid caterpillars, and once a centipede and spider (Mason & Lefroy, 1912).

VOICE and CALLS. A loud, high-pitched cackling 'laugh', rather like the Whitebreasted Kingfisher's but less emphatic and more tinny. Drums on stems and boughs of trees in rather muffled bursts — *dr-r-r-r-r-r* — of 2 or 3 seconds duration, chiefly during the breeding season as advertisement. Nest-young emit a screechy hissing to deter a human intruder, while the parents flit distractedly from branch to branch in the vicinity, pecking viciously on the substrate in anger and frustration.

BREEDING. *Season*, February to July, chiefly March and April. Excavation often commences a month or more before egg-laying. Two successive broods sometimes raised. *Nest*, a neat round hole (c. 7 or 8 cm across) leading to the shaft and widened egg-chamber, usually cut between 3 and 6 metres from the ground, occasionally 10 or more. Mango, *Albizia*, *Erythrina* and other softwood trees, and stems of coconut and palmyra palms usually selected; sometimes a horizontal branch with entrance on the underside. *Eggs*, normally 3, china white with a glossy surface. Average size of 50 eggs 28.1 × 20.9 mm (Baker). Both sexes share all the domestic chores; period of incubation undetermined. Despite nest-sanitation practised by the parents, nests usually foul-smelling.

MUSEUM DIAGNOSIS. Upperparts rich golden yellow; rump black; shoulders black with conspicuous creamy white spotting; chin, throat and breast black, streaked with white; white of lower parts pure.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	136-148	31-43	23-27	89-93 mm (SA)

Weight 11 ♂ ♀ 89-121 (aver. 100.3) g — SA.

200

PICIFORMES

FIELD CHARACTERS. As in 819. See Museum Diagnosis.

Distinguished from the very similar Threethroated Goldenback (825), especially in flight, by its black lower back and rump v. crimson.

STATUS, DISTRIBUTION and HABITAT. Resident; common. West coast of India southward from c. 16°N. through Goa, western Mysore (Malnaad) and Kerala; low country and foothills, locally up to c. 1000 m. Affects light forest, wooded urban and rural compounds, fruit gardens surrounding the backwater homesteads, and rubber, cashew, and coconut plantations, etc.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 819 and other races, q.v.

BREEDING. *Season*, February–March and July–August; possibly staggering through the intervening months. *Nest, eggs* (c/3) and breeding biology as in 819.

MUSEUM DIAGNOSIS. Upperparts rich golden olive-yellow; black of rump much restricted and obscured by an olive wash; black of shoulders practically obscured by golden olive wash, the spots small or obsolete and yellowish cream in colour. Chin, throat and breast black with fine white spotting and barring; white of lower plumage with a creamy buff tinge.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
6 ♂♂	136-151	39-43	25-26	86-95 mm
8 ♀♀	138-149	39-41	23-25	85-94 mm
				(HW)

COLOURS OF BARE PARTS. Iris brown, brownish crimson, or crimson. Bill slaty brown (horny black), greyish laterally at base of lower mandible; mouth greyish pink. Legs and feet greenish grey; claws horny brown.

822. *Dinopium benghalense jaffnense* (Whistler)

Brachypterus benghalensis jaffnensis Whistler, 1944, Spolia Zeylanica 23: 206

(Iluppakkadavai, Ceylon)

Baker, FBI No. 1397, Vol. 4: 70

LOCAL NAMES. *Pita rāng kerellā* (Sinhala); *Mārāmbkōtti*, *Tachchan kūrūri* (Tamil, Ceylon).

SIZE. Myna ±; length c. 28 cm (11 in.).

FIELD CHARACTERS. As of 819; slightly smaller. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Race endemic in Ceylon. Moderately plentiful in the Jaffna peninsula and well-wooded areas to the north of Puttalam and Trincomalee; less common in the inland northern forest area, north of Kekirawa (North Central Province). Southwards, it meets and intergrades with the Redbacked Woodpecker (823) — Phillips. Largely a bird of open coastal areas.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 819 and the other peninsular races. See Museum Diagnosis.

BREEDING. *Season*, 'about April' (Wait). *Nest, eggs*, etc. doubtless as in 819 and 823, but very little definitely recorded.

MUSEUM DIAGNOSIS. Differs from peninsular *puncticollis* (820) in the darker and duller tint of the upperparts with their more olive wash both on mantle and wings,

WOODPECKERS

201

and by the smaller and more 'arrow-headed' spots on the wing-shoulders. Lower plumage creamy buff (v. white) with more heavily defined black markings from lower breast to under tail-coverts. Also by smaller size and lighter, more pointed bill. Very close to the Kerala population (821); separable from it chiefly on size and bill.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
7 ♂♂	130-138	34-39	24-25	78-85 mm
6 ♀♀	132-135	35-36	23-24	75-85 mm (HW)

COLOURS OF BARE PARTS. As in 821.

823. *Dinopium benghalense psarodes* (A. Lichtenstein)

Picus psarodes A. Lichtenstein, 1793, Catalogus rerum rarissimarum Hanburgi: 18 ('Ostindien', restricted to Ceylon by Meise, 1950, Ardea 38: 187)

Picus erithromorphos Vieillot, 1818, Nouv. Dict. d'Hist. Nat. 26: 73
(Java, *errone* = Ceylon)

Baker, FBI No. 1399, Vol. 4: 71

Plate 60, fig. 14

LOCAL NAMES. *Pita rāts kerellā* (Sinhala); *Mārāmkottā*, *Thachchan kūrūrī* (Tamil, Ceylon).

SIZE. Myna +; length c. 28 cm (11 in.).

FIELD CHARACTERS. Similar, sex for sex, to the Goldenbacks (e.g. 819, 822) but with crimson replacing golden yellow in the upper plumage. Confusable with Ceylon Crimsonbacked Woodpecker (863), but slightly smaller size, brighter red back, bolder black and white markings on sides of head, shorter darker coloured bill, and different call-notes, diagnostic.

STATUS, DISTRIBUTION and HABITAT. Race endemic in Ceylon; the commonest woodpecker in the island. Plentiful throughout the well-wooded hills to c. 1700 m; also throughout the lowlands except the forested coastal area north of Puttalam, Kekirawa and Trincomalee where it meets and intergrades with the goldenbacked *jaffnese* (822)—Phillips. Affects coconut plantations, wooded gardens and open jungle; avoids heavy forest.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 822, and in 819 and other peninsular races.

BREEDING. Season, overall December to September, chiefly March to June and August-September. Nest, eggs (c/3) and breeding biology as in 819 and other races. Average size of 13 eggs 29 × 21.3 mm (Baker).

MUSEUM DIAGNOSIS. See Key to the Subspecies and Field Characters. Black on sides of head and lower plumage greater in extent, and white less than in the goldenbacked races; white markings on chin and throat confined to spots or narrow bars.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
12 ♂♂	135-141	35-39	23-24	83-90 mm
11 ♀♀	130-140	32-40	24-25	77-93 mm
Weight 1 ♀ 97 g (SDR).				(HW, SDR)

COLOURS OF BARE PARTS. As in 821.

WOODPECKERS

203

825. *Dinopium javanense malabaricum* Whistler & Kinnear

Dinopium javanense malabaricum Whistler & Kinnear, 1934, Jour. Bombay nat. Hist. Soc. 37: 294 (Manantoddy, Wynaad). New name for *Picus rubropygialis* auct., not of Malherbe, 1845

Baker, FBI No. 1400, Vol. 4: 73

Plate 60, fig. 16

LOCAL NAMES. *Mānu tolachhi* (Telugu); *Mārām tolachhi*, *Thachchan kūrūrī* (Tamil); *Mārāmkottā* (all woodpeckers, Malayalam).

SIZE. Myna +; length c. 28 cm (11 in.).

FIELD CHARACTERS. Superficially rather similar to Kerala Goldenbacked Woodpecker (821), also with crimson crown and occipital crest in male, but golden olive of upperparts mixed with orange or scarlet, and lower back and rump crimson (v. black). A white supercilium to nape; sides of head boldly striped black and white. Below, buffy white with a black stripe down middle of chin and throat and prominent black scalloping or scale-like markings on breast and abdomen.

Female similar to male but crown and occipital crest black instead of crimson, and stippled with white.

May be confused in the field also with *Chrysocolaptes l. chersonesus* (862)—also with red rump—but its slightly smaller size and black nape (v. white in 862) are diagnostic. The calls of the two are also distinct.

STATUS, DISTRIBUTION and HABITAT. Range almost completely coincident with that of 821: southwestern India southward from c. 16°N. through Goa, western Mysore (Malnaad), western Tamil Nadu (Nilgiri and Palni Hills) and Kerala; low country and hills up to c. 2300 m. Affects moist-deciduous and evergreen forest, especially in the foothills—more humid facies than usual with 821.

The species *javanense*, like the several other Indo-Malayan elements in the fauna of the heavy-rainfall areas of southwestern India, has a remarkably disjunct range, the nearest related population in Assam (826) being separated from *malabaricum* by a gap of more than 1500 km.

GENERAL HABITS. Typical woodpecker. Keeps in pairs, often associated with mixed hunting parties of wood shrikes, racket-tailed drongos, and other insectivorous birds in forest.

FOOD. Ants, grubs of beetles, and other insects.

VOICE and CALLS. A rather weak tinny scream, quite distinct from the call of the commoner Goldenbacked (821). Also drums on wood like most other woodpeckers, particularly during the breeding season.

BREEDING. Season, overall January to April-May, chiefly February and March. Nest, the usual hole excavated in a tree-trunk or branch from under 2 metres to 10, normally below 5 m. Eggs, 2 or 3, white, oval, unmarked. Average size of 15 eggs 29.4 × 20.4 mm (Baker). Breeding biology not specifically recorded; presumably as in 821. Incubation period undetermined.

MUSEUM DIAGNOSIS. Differs from the spatially separated Assam-Burma subspecies (826) in its somewhat smaller size, and a strong olive wash in the golden colour of the upper plumage.

202

PICIFORMES

824. Himalayan Goldenbacked Threestoed Woodpecker. *Dinopium shorii shorii* (Vigors)

Picus shorii Vigors, 1832 (1830-31), Proc. Zool. Soc. London (1): 175 (Himalayas)
Baker, FBI No. 1401, Vol. 4: 74

LOCAL NAMES. None recorded.

SIZE. Pigeon ±; length c. 31 cm (12 in.).

FIELD CHARACTERS. A largish goldenbacked woodpecker with crimson crown and occipital crest (♂), crimson rump and black tail. Hindneck black, the black continued forward as a black stripe to behind eye; a prominent white supercilium to nape; a broad white band down either side of neck. Black moustachial streaks continued as a double line down centre of throat, with the intervening space pale brown. Below, breast and underparts buffy white boldly streaked and scalloped with black.

Female similar to the male but with forehead and forecrown brownish black instead of crimson; crown and crest black with long white streaks.

STATUS, DISTRIBUTION and HABITAT. Resident; from Garhwal eastward through Nepal, Sikkim, Bhutan and NEFA. Also Nagaland, Manipur and East Pakistan (hill tracts). Locally not uncommon in the Himalayan terai, bhabar, duars and foothills, up to c. 700 m. Co-existing with *Dinopium benghalense*, but evidently more narrowly restricted to climax forest and less adaptable than *benghalense* to conditions created by increasing deforestation, therefore less widespread. Affects tall deciduous and semi-evergreen forest.

Extralimital. Chin and Kachin hills, Arakan Yomas and Burmese hill ranges south to Thayemyo (Peters).

GENERAL HABITS, FOOD, VOICE and CALLS. As in other goldenbacked woodpeckers (cf. 819). Nothing specifically recorded.

BREEDING. Season, not definitely known; eggs have been taken apparently only thrice, all in the first half of April. Nest, the typical woodpecker boring in a tree-trunk. Eggs, 3 (sometimes 2 ?), white. Average size of 8 eggs 29.9 × 20.8 mm (Baker).

MUSEUM DIAGNOSIS. Hallux (inner hind-toe) absent. See Key to the Species.

MEASUREMENTS

Gecinulus Blyth, 1845, Jour. Asiat. Soc. Bengal 14 (1): 192. Type, by monotypy.

Picus grantia Horsfield

Only three toes present, the hallux or inner hind-toe lacking. Bill short, compressed; culmen blunt, nearly straight; nasal ridge obsolete. Nostrils close to base of bill; nasal plumes short. Tail-feathers broad, not acuminate; outer pair longer than coverts but much shorter than the rest, which are regularly graduated. Crest short, inconspicuous.

WOODPECKERS

209

Satpura mountain trend. This needs investigation. Not uncommon, but very local, in the heavy-rainfall zone north to Goa; thinly distributed, rare or sporadic elsewhere in its range — plains, foothills and up to c. 1200 m elevation. Affects climax and secondary forest in evergreen and moist-deciduous biotope. Partial to mixed bamboo jungle and to lofty natural shade trees in coffee and cardamom plantations in SW. India. Very sensitive to deforestation and disturbance by humans, soon forsaking localities where lumbering is in progress or the forest has been felled. Thus many gaps in its present range doubtless due to disappearance of appropriate habitats.

Extralimital. Represented in Burma by the closely similar subspecies *feddeni* (Plate 54) with scarlet-crimson (v. deep crimson) crown and nape.

GENERAL HABITS. Typical of the woodpeckers and very similar to those of the Great Slaty (829). Keeps in noisy pairs or loose family parties of 3 or 4 chiefly to large forest trees. Flight stately and unhurried, with deliberate wing-beats reminiscent of a crow's or blue jay's in silhouette.

FOOD. Chiefly ants (*Camponotus* and others), termites, and grubs and pupae of wood-boring beetles. Stomach of one example contained numerous small honey-bees (*Apis florea*) taken from a comb in a tree hollow; the bird's forehead and chin feathers were clotted with honey.

VOICE AND CALLS. A wild resounding metallic single note *chiank*, uttered by both sexes, every 2 or 3 seconds 3 or 4 times in succession, both while clinging to a tree-trunk and in flight from one part of the forest to another. A short ringing laugh or chuckle uttered on the wing, reminiscent of the cry of the Malabar Grey Hornbill (768). In addition a loud, resonant, far-carrying mechanical drumming like a burst of machine-gun fire, particularly in the breeding season, evidently to advertise its presence and territory: this responded to in like manner by other birds in the distance.

BREEDING. Season, principally January to March. *Nest*, the usual woodpecker hole, c. 14 cm in diameter, excavated in rotten trunks of large branchless trees at heights between c. 8 and 16 metres from the ground. The shaft and egg-chamber are often up to 50 or 60 cm deep. *Eggs*, normally 2, sometimes said to be 3 or 4, white broad ovals, measuring c. 35 × 23 mm. Both sexes take part in excavating the nest, incubation (?) and feeding the young. Incubation period undetermined. The squabs are greatly relished as food by the locals in Bastar dist., Madhya Pradesh, and eagerly sought; hence, probably, its rarity and inordinate shyness in that area.

MUSEUM DIAGNOSIS. See keys to the Species and Subspecies.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	213-225	63-69	37-43	139-165 mm
♀♀	212-226	59-65	36-39	130-170 mm (SA)

COLOURS OF BARE PARTS. Iris yellowish white (adult ♂♀), or pearl grey (imm.). Bill horny slate, paler on sides of lower mandible. Legs and feet greyish slate; claws horny brown.

832. *Hypopicus hyperythrus marshalli* (Hartert)

Dryobates hyperythrus marshalli Hartert, 1912, Vög. pal. Fauna 2 (7): 926 (Murree) Baker, FBI No. 1359, Vol. 4: 31

LOCAL NAMES. None recorded.

SIZE. Bulbul ±; length c. 20 cm (8 in.).

FIELD CHARACTERS. As of 833. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident. The western Himalayas from Kashmir and Ladakh eastward through Punjab and Himachal Pradesh to Kumaon, where it intergrades with the nominate race. Affects subtropical pine and moist temperate forest (horse-chestnut, silver fir, etc.), above c. 1600 m; breeding up to c. 3000 m.

GENERAL HABITS, FOOD. As in 833, q.v.

VOICE AND CALLS. Described as a long rattling, but not loud, cry, running down at the finish, 'May be likened to the rapid running down of the works of a small clock with a broken mainspring or to the rapid running out of a large fishing reel' (Magrath, JBNHS 19: 153).

BREEDING. Season, April-May. *Nest* and *eggs* (c/4 or 5 ?) as in 833. Average size of 13 eggs from Murree and the Galis 24.3 × 18.2 mm (Baker). Breeding biology as in 833.

MUSEUM DIAGNOSIS. Differs from nominate *hyperythrus* (833), sex for sex, in being larger. Also the male has the crimson on sides of neck and head more extensive.

MEASUREMENTS

	Wing	Bill (from feathers)

Baker, FBI No. 1415, Vol. 4: 91

Plate 62, fig. 9

LOCAL NAMES. None recorded.

SIZE. Pigeon +; length c. 38 cm (15 in.).

FIELD CHARACTERS. A large black woodpecker similar to 830 but smaller, with the black duller and more brownish and no white in the plumage. Forehead, crown, crest, and moustachial patch crimson in male; only hindcrown and nape in female.

STATUS, DISTRIBUTION AND HABITAT. Resident; fairly common. Andaman Islands, in high evergreen forest.

GENERAL HABITS. Very like 830, q.v. Frequents lofty trees in high forest. Each individual has two or three favourite dead stumps to which it repairs two or three times daily to drum at intervals on dead wood, producing an extraordinarily loud rattle audible for a mile or more and usually answered from several other parts of the forest (Butler, JBNHS 12: 560). Evidently descends to the ground on occasion to feed on ants etc. like other woodpeckers.

FOOD. Not specifically recorded; presumably as in 830.

VOICE AND CALLS. 'A loud chattering *kuk-kuk-kuk* (or *kik-kik-kik*) ending with a whistling *kui*' (HA).

BREEDING. Season, February-March. *Nest*, a hole drilled in a dead tree-trunk or large branch between c. 6 and 14 m up, in fairly open forest (BEO and Wickham). *Eggs*, 2, white. Average size of twelve 33.4 × 23.3 mm (Baker). No other particulars recorded.

MUSEUM DIAGNOSIS. See key to the Subspecies and Field Characters.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂♀	180-190	41-47 (from feathers)	32-33	130-147 mm (Baker, HA)

COLOURS OF BARE PARTS. Iris creamy white to pale bright yellow. Bill plumbeous black; tip paler and translucent. Legs and feet greenish or plumbeous black.

831a. *Black Woodpecker*. *Dryocopus martius khamensis* (Buturlin)

(See Appendix, p. 259)

Genus *HYPOPICUS* Bonaparte

Hypopicus Bonaparte, 1854, Consp. Volut. Zygodact., No. 62: 8. Type, by original designation, *Picus hyperythrus* Vigors

Crest obsolete. Bill slender, compressed and truncated; culmen straight and angulate, with a short nasal ridge extending close down to commissure for rather less than half length of bill. Nostrils basal with short nasal plumes. Gonys long; chin angle close to gape and concealed by bristles. Fourth toe (outer posterior) slightly longer than 3rd (outer anterior). Outermost pair of rectrices shorter than tail-coverts.

HYPOPICUS HYPERYTHRUS (Vigors): RUFOUSBELLIED WOODPECKER

Smaller; wing 126 mm or less.....*H. h. hyperythrus*
Larger; wing 126 mm or more; red on head extends behind ear-coverts.....*H. h. marshalli*

212

PICIFORMES

FIELD CHARACTERS. A practically uncrested black-and-white and chestnut woodpecker.

Male. Above, crown and nape crimson. Upper plumage, to rump, broadly barred black and white; wings and tail black, largely spotted and barred with white. *Below*, chin grey; throat, sides of neck and underparts bright chestnut; under tail-coverts pale crimson.

Female. Crown and nape black spotted with white; rest as in male.

Young (immature). Like female but barred with dusky on underparts.

STATUS, DISTRIBUTION AND HABITAT. Resident. Eastern Kumaon and Nepal eastward in the Himalayas through Sikkim, Bhutan, and NEFA. Cachar, Nagaland, Manipur, Mizo and East Pakistan (hill tracts), from c. 800 to 4100 m. Affects pine, moist temperate and subtropical forest—rhododendron, oak, horse-chestnut, etc.

Extralimital. Northern Burma hills to western Yunnan and Sikkim; northern Thailand.

GENERAL HABITS. A quiet woodpecker keeping singly or in separated pairs, frequently in association with roving bands of insectivorous birds in Himalayan forest, usually working fairly high up on the trunks of large trees.

FOOD. Ants, grubs of beetles, and other insects. Has been observed catching white butterflies at chestnut flowers by Whistler.

VOICE AND CALLS. As in 832. Drumming on dead stumps commonly indulged in by both sexes.

BREEDING. Season, April-May. *Nest*, the typical woodpecker hole bored 5 to 6 m or so up in a tree-trunk. *Eggs*, clutch-size undetermined: believed to be 4 or 5, white. Average of 15 eggs 22.2 × 16.5 mm (Baker). Evidently both sexes incubate; other particulars unrecorded.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.; for subspecies Key.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♀	114-122	23-28	19-22	69-87 mm (SA)

Weight 10 ♂♂ 42-53 g; 6 ♀♀ 42-50 g (SA, GD).

COLOURS OF BARE PARTS. Iris reddish brown. Bill: upper mandible black, lower greenish yellow. Legs and feet blackish grey (SDF).

Genus *PICOIDES* Lacépède

Picoides Lacépède, 1799, Tabl. Ois.: 7. Type, by subsequent designation, *Picus tridactylus* Gmelin, i.e. *Picus tridactylus* Linnaeus

Very close to *Hypopicus* but bill comparatively stouter with a nasal ridge on each side extending over more than half its length and equidistant between culmen and commissure; gonyes sharply angulate. General coloration black or brown spotted and barred with white, and with crimson here and there. Wing long, pointed or slightly rounded. Outer hind toe longer than outer front toe. Crest more or less rudimentary.

Plate 61, fig. 12

LOCAL NAMES. *Gihan* (Brahui); *Tukok* (Baluchi); *Burdi tkeri* (S. Kalat).

SIZE. Myna —; length c. 22 cm (8½ in.).

FIELD CHARACTERS. A medium-sized black and white woodpecker, very similar to the Kashmir Pied (836) but with the scapulars glistening white instead of black, making the shoulder-patches larger and even more prominent. Below, chin, breast and abdomen white; lower abdomen, vent and under tail-coverts crimson. Crown and occiput crimson in male, black in female.

STATUS, DISTRIBUTION and HABITAT. Resident; fairly common but local. West Pakistan (Baluchistan, Sind, W. Punjab west of Jhelum R., including Peshawar dist.). Generally at low elevations in comparatively arid areas, but recorded at c. 1600 m in the Salt Range, and at c. 2200 m in Khwaja Amran Range, Baluchistan (Christison). Affects babool and tamarisk jungle in riverain tracts (often among sand-dunes), euphorbia and thorn scrub in semi-desert biotope, and sheesham (*Dalbergia*) and other tree plantations in canal-irrigated desert colonization areas.

Extralimital. SE. Iran.

GENERAL HABITS. Typical woodpecker. Partial to seeking food near the ground on fallen trees and branches, euphorbia stems, wooden stakes, fence-posts and the like.

FOOD. Mainly ants, termites and grubs of beetles.

VOICE and CALLS. *Toi-whit, toi-whit, toi-whit* rapidly repeated (Whistler) at rest and in flight. A frequently uttered *tr-r-r-r* (T. R. Bell). In the breeding season, especially, both sexes drum in intermittent bursts at frequent intervals on a selected rotten branch, producing an inordinately loud rolling or kettle-drum effect.

BREEDING. Season, principally March and April. Nest, the usual woodpecker hole drilled in a babool, *kandi* (*Prosopis*), *Salvadora persica*, tamarisk or suchlike tree, between 1 and 4 metres from the ground. Eggs, 3 or 4, white. Average size of 12 eggs 22.2 × 17.0 mm (Baker). Both sexes evidently share all the domestic chores. Period of incubation undetermined.

MUSEUM DIAGNOSIS. See Field Characters and Key to the Species.

MEASUREMENTS

8 ♀♀	111-120	24-27	—	65-70 (4) mm (CBT, HW)

COLOURS OF BARE PARTS. Iris brown to crimson. Bill dark slaty grey or bluish plumbeous, paler on lower mandible. Legs and feet greyish plumbeous.

214

PICIFORMES

FIELD CHARACTERS. A medium-sized woodpecker, very similar to the Garhwal Pied (837), q.v., but with crown black (v. crimson) in male. See Key to the Species and Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident. Cachar dist. (Assam), Nagaland, Manipur and Mizo (?), between c. 2000 and 3000 m, in oak, pine and subtropical wet forest.

Extralimital. Western China in western Szechuan, eastern Sikang etc., extending north to c. 33° and southward into northern Burma (Peters).

Picoides major

Breeding range

1 *P. m. stresemanni* (834).

2 Other races (about 26) extralimital.

GENERAL HABITS, FOOD, VOICE and CALLS. Nothing specifically recorded in our limits.

BREEDING. Season unrecorded though *sic* Baker it breeds in Cachar and Manipur; presumably March and April as in adjacent northern Burma. Nest and eggs (c/3) as in 837. Average size of 12 Burmese eggs 27.6 × 19.6 mm (Baker).

MUSEUM DIAGNOSIS. Very similar to *P. himalayensis* (837) with the upperparts almost identical. Differs from it in having the crown black in male, the crimson confined to the occiput; crimson of under tail-coverts extending to abdomen.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	130-138	26-31	c. 20-21	79-87 mm (Baker)

COLOURS OF BARE PARTS. Iris crimson. Bill: upper mandible blackish lead colour, lower mandible paler lead colour. Legs brownish green (Baker).

Key to the Subspecies

Paler below, more grey than fulvous..... *P. h. albescens*Darker below, more rufous or fulvous..... *P. h. himalayensis*836. *Picoides himalayensis albescens* (Baker)*Dryobates himalayensis albescens* Baker, 1926, Bull. Brit. Orn. Cl. 46: 70

(Goona [?], Kashmir)

Baker, FBI No. 1361, Vol. 4: 34

Plate 61, fig. 16

LOCAL NAMES. *Hür koel*, *Maköt*, *Koel kökür* (Kashmir); *Türkän* (Chamba).

SIZE. Myna ±; length c. 25 cm (9½ in.).

FIELD CHARACTERS. As of 837. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident, fairly common; subject to some seasonal altitudinal movement. The Safed Koh and western Himalayas from the Afghanistan frontier through Chitral, Gilgit, Kashmir, northern Punjab and Himachal Pradesh. Between c. 1700 and 3300 m in summer; usually below c. 2000 m in winter. Where occurring together, generally occupies a higher zone than *P. auriceps* (842) or *P. macri* (845). Affects fir, oak, rhododendron and mixed hill forest with a predilection for chestnut trees for nesting.

Extralimital. Nuristan, NE. Afghanistan (Paludan).

GENERAL HABITS. Typical woodpecker. Keeps in pairs. Works energetically up and around tree-trunks and along the sides and undersurface of moss-covered branches in jerky spurts, occasionally sliding back a few spurts in 'reverse gear' to re-investigate a promising spot. Along with several other Himalayan woodpeckers has been observed to drill rows of neat small holes in parallel rings round the stems of medium-sized trees, a few centimetres apart, like the New World sapsuckers. The significance of this habit needs study.

FOOD. Insects, chiefly grubs of beetles collected from under the bark or moss. Largely also seeds of various conifers, e.g. the Chir pine (*Pinus longifolia*). Plucks and wedges the cones in a cleft of bark or in angle between stem and branch, hacks them open with the bill (often months before they would mature and open naturally), and extracts the seeds; also kernels of walnuts, hazelnuts and acorns treated in the same way.

VOICE and CALLS. 'A volley of loud ringing cries uttered in flight' (Bates). 'A persevering *tri-tri-tri-tri*' (Paludan). Both sexes, moreover, drum on dead tree-stems etc. — especially during the breeding season.

BREEDING. Season, April to June. By mid June most first broods have flown from the nest. Nest, the usual woodpecker boring in the main trunk or on the underside of a large sloping bough, between 2 and 15 m from the ground. The trees most commonly selected are pine, cherry, apricot, willow and chestnut, the last being preferred wherever available. Eggs, 3 to 5 — mostly 4 — pure white, glossy. Average size of 28 eggs 26.2 × 19.0 mm (Baker). Both sexes share in excavating the nest-hole, incubation and tending the young. Incubation period undetermined.

WOODPECKERS

217

MUSEUM DIAGNOSIS. Sex for sex similar to *P. h. himalayensis* (837) but much paler below; chin, throat and breast white or greyish white, and entire underparts much less fulvous. White bars on the tail somewhat broader and purer white.

MEASUREMENTS

	Wing	Bill (from feathers)	
♂ ♀	127-136	28-32	mm
		(Baker)	

Wing 3 ♂♂ 132-137; 5 ♀♀ 128-133 mm. Weight 3 ♂♂ 72-74 g; 6 ♀♀ 59-67 g (Paludan).

COLOURS OF BARE PARTS. As in 837.

837. *Picoides himalayensis himalayensis* (Jardine & Selby)

Picus himalayensis Jardine & Selby, 1836, in Jardine's Ill. Orn. 3, Sig. D., pl. 116 and text (Mussoorie, 6500 feet)
Baker, FBI No. 1360, Vol. 4: 32
Plate 61, fig. 15

LOCAL NAMES. None recorded.

SIZE. Myna ±; length c. 25 cm (9½ in.).

FIELD CHARACTERS. A medium-sized pied woodpecker.

♂, x c. 1

Male. Above, crown and crest crimson; lores, a narrow supercilium, cheeks and ear-coverts whitish with a broad black moustachial streak below extending to sides of neck. Back and upperparts black with a prominent white elongate patch on each shoulder and small white spots and barring on the wing-quills. Below, fulvous, paler on chin and throat, darker on breast and abdomen; under tail-coverts crimson.

Female. Similar but with crown and occiput black instead of crimson.

Young (immature). Like female but darker below with faint streaks or narrow dark edges to the feathers. Crown in ♂ crimson tipped with black.

STATUS, DISTRIBUTION AND HABITAT. Resident, fairly common; subject to some seasonal altitudinal movement. The Garhwal, Kumaon and western Nepal Himalayas between c. 1000 and 3000 m: commonest above c. 2000 m. Affects hill forest of fir, oak, rhododendron, etc.

WOODPECKERS

219

VOICE AND CALLS. Little and unsatisfactorily recorded. 'An occasional low *put* . . . *put*' (Lister), and the characteristic drumming, chiefly in the breeding season.

BREEDING. Season, April-May. Nest, the typical woodpecker boring in a tree-trunk, 1 or 2 metres up, in dense forest commonly between c. 2000 and 3000 m alt. Eggs, 2 to 4, white. Average size of 20 eggs 27.8 × 19.8 mm (Baker). Details of breeding biology not recorded.

MUSEUM DIAGNOSIS. See Key to the Species; for details of plumage Baker, loc. cit.

Young (both sexes) in early phase like female, with the crown black. In a later phase immature male has entire crown tipped with orange-red or crimson.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	123-135	31-35	22-25	76-86 mm
Weight (winter) 5 ♂♂ 70-80 g; 5 ♀♀ 61-73 g.				(SA, SDR)

COLOURS OF BARE PARTS. Iris reddish brown to crimson; orbital skin slaty grey. Bill plumbeous, blackish on upper mandible. Legs and feet dull green or greenish plumbeous; claws horny.

Baker, FBI No. 1364, Vol. 4: 36
Plate 61, fig. 18

LOCAL NAME. *Sadyer mong prek* (Lepcha).

SIZE. Myna ±; length c. 25 cm (9½ in.).

FIELD CHARACTERS. A medium-sized pied woodpecker. Back entirely black; middle tail-feathers black, outer barred with white. Underparts yellowish fulvous, streaked with black; vent and under tail-coverts light crimson. Hindcrown and nape crimson in male, black in female.

STATUS, DISTRIBUTION AND HABITAT. A high-elevation woodpecker. Resident between c. 1700 and 3500 m even in winter; in summer up to c. 4000 m. From west-central Nepal eastward through Sikkim, Bhutan and NEFA. Assam in the higher hills of Cachar dist., Nagaland, Manipur and Mizo. Affects pine, oak, rhododendron and subtropical wet forest.

Extralimital. N. Burma, Shan States and N. Vietnam.

GENERAL HABITS. Typical woodpecker. Keeps singly or in pairs. Hunts high up on moss-covered tree-trunks and branches amongst the canopy foliage, frequently in association with the itinerant bands of small insectivorous birds. Also searches for food on decaying storm-blown trees bestrewn the forest floor.

FOOD. Larvae of beetles and other insects.

¹ Re-examination of the type series of 839, *Picoides darjellensis fumidus* (Ripley) from Nagaland compared with material from Nepal within a year, shows that the sole difference is a darker, more smoky colour on the lower breast. This is probably clinal, and it seems unwise to maintain the subspecies on this single colour difference (SDR).

PICIFORMES

220

Young (immature) male like female but with the whole crown more or less tipped with crimson.

STATUS, DISTRIBUTION AND HABITAT. A high-elevation woodpecker with a more or less overlapping altitudinal range with *P. darjellensis* (838) both summer and winter. Nepal eastward through Sikkim, Darjeeling dist., Bhutan, and NEFA; from c. 700 to 4000 m in moist-deciduous and evergreen forest — oak, rhododendron, etc.

GENERAL HABITS. Not appreciably different from 838, q.v. Behaviour rather like a tree-creeper's, flying from dead tree to dead tree and searching each methodically.

FOOD. Insects and grubs. Also nectar of flowers, e.g. rhododendron, procured by the 'short-cut' method, i.e. boring hole at base of corolla (SA).

VOICE AND CALLS. 'Loud for the size — a rather monotonous chip uttered at intervals when searching a tree, and rather more quickly when flying' (Cranbrook). 'Occasional rather soft, clear *putik*' (Lister).

BREEDING. Season, April-May. Nest (in dense tree jungle) and eggs (c/2-4) typical of the woodpeckers. Average size of 12 eggs 23.3 × 16.8 mm (Baker). Breeding biology not specifically recorded.

MUSEUM DIAGNOSIS. See Field Characters, and keys to the Species and Subspecies.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	97-103	18-21	17	57-66 mm
			(remarkably consistent!)	(SA, BB, SDR, Stresemann)

Weight (winter) 1 ♂ 35 g; 2 ♀♀ 26, 28 g (SA).

COLOURS OF BARE PARTS. Iris brown or reddish brown. Bill pale plumbeous, darker on culmen and tip. Legs and feet plumbeous or greenish plumbeous.

840a. *Picoides cathpharius ludlowi* (Vaurie)

Dendrocopos cathpharius ludlowi Vaurie, 1959, Amer. Mus. Novit., No. 1946: 23 (Tseira, Pome, 'southeastern Tibet' = southeast Sikkim)
Not in Baker

LOCAL NAMES. None recorded.

SIZE. Bulbul —; length c. 18 cm (7 in.).

FIELD CHARACTERS. As of 840. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Valley of the Po Tsangpo, SE. Tibet, between c. 95°5' and 95°15'E., therefore doubtless encroaching into our limits in that sector of NEFA.

GENERAL HABITS, FOOD, VOICE AND CALLS. Nothing specifically recorded.

BREEDING. Unrecorded.

MUSEUM DIAGNOSIS. Similar to *cathpharius* and *pyrrhithorax* (840, 841) in having the ear-coverts bordered posteriorly with red in both sexes, very broadly so in the male. Red patch on breast much more well marked and under tail-coverts much redder than in nominate *cathpharius* (Vaurie).

MEASUREMENTS AND COLOURS OF BARE PARTS. As in 840.

WOODPECKERS

221

841. *Picoides cathpharius pyrrhorthorax* (Hume)

Picus pyrrhorthorax Hume, 1881, Stray Feathers 10: 150
(Aimole, eastern Manipur Hills)

Dendrocopos cathpharius cruentipictus Koelz, 1954, Contrib. Inst. Regional Exploration, No. 1: 22 (Sangau, Lushai Hills)
Baker, FBI No. 1366, Vol. 4: 38

LOCAL NAME. *Khupi uoiu* (Angami Naga).

SIZE. Bulbul —; length c. 18 cm (7 in.).

FIELD CHARACTERS. As of 840. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Assam hills south of Brahmaputra R. (Khasi and Cachar), Nagaland, Manipur and Mizo hills, above c. 1300 m. In mixed deciduous, tropical semi-evergreen and subtropical wet forest.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 840.

BREEDING. Unknown.

MUSEUM DIAGNOSIS. Male differs from that of nominate *cathpharius* (840) in having a broad crimson gorget on foreneck and upper breast, and under tail-coverts nearly all crimson; black striations on underparts also broader.

Female like ♀ *cathpharius* but with more crimson on upper breast and under tail-coverts.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	97–101	16–17	c. 15	59–60 mm (Baker)

COLOURS OF BARE PARTS. Iris lac-red. Bill leaden dusky, paler at base of lower mandible. Legs and feet dull sap-green (Hume).

PICOIDES AURICEPS (Vigors): BROWNHEADED PIED WOODPECKER

Key to the Subspecies

- Larger; wing c. 114–121 mm.....*P. a. auriceps*
Smaller; wing c. 105–115 mm.....*P. a. incognitus*

842. *Picoides auriceps auriceps* (Vigors)

Picus auriceps Vigors, 1831 [Apr. 6], (1830–31), Proc. Zool. Soc. London (1): 44
(Simla, restricted by Baker, 1921, JBNHS 28: 97)

Picus brevifrons Vigors in Gould, 1831, Century of Birds, Himalayan Mts, text to pl. 52 (Hilly districts of India = Simla ride Rand & Fleming, 1956, tom. cit.)
Baker, FBI No. 1370, Vol. 4: 42

Plate 61, fig. 6

LOCAL NAMES. None recorded.

SIZE. Bulbul; length c. 20 cm (8 in.).

FIELD CHARACTERS. A smallish pied woodpecker.

Male. *Above*, forehead and forecrown umber-brown; occipital crest golden yellow in front, crimson behind; a broad brown moustachial streak extending down side of neck. Upperparts brownish black, transversely barred with white. *Below*, fulvescent white, longitudinally streaked with

WOODPECKERS

223

SIZE. Bulbul; length c. 20 cm (8 in.).

FIELD CHARACTERS. As for 842. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident; fairly common. Nepal, eastward from around 81°30'E. (Dailekh dist.) to the region of Kathmandu; from c. 700 to 2400 m, occasionally higher and evidently breeding to c. 3000 m. In open dry and moist temperate and pine forest.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 842.

BREEDING. Season, nest and eggs as in *auriceps*.

MUSEUM DIAGNOSIS. Similar to nominate *auriceps* but smaller. In both sexes forecrown more fulvous, less brownish, and streaking on breast slightly more conspicuous. Some females are brighter yellow, more golden less brownish on nape than females of *auriceps*, but this difference not constant.

MEASUREMENTS. Wing: 14 ♂♂ (Nepal) 105–115 (av. 109.9) mm against 13 ♂♂ (Simla) 114–121 (av. 117.4) mm — Vaurie.

Weight (summer) 3 ♂♂ 38–44 g; 3 ♀♀ 38–40 g (Dieselhorst).

COLOURS OF BARE PARTS. As in 842.

844. *Stripectus* Pied Woodpecker. *Picoides atratus* (Blyth)

Picus atratus Blyth, 1849, Jour. Asiat. Soc. Bengal 18 (2): 803 (Tenasserim)
Baker, FBI No. 1369, Vol. 4: 41

Plate 61, fig. 8

LOCAL NAMES. None recorded.

SIZE. Bulbul ±; length c. 21 cm (8 in.).

FIELD CHARACTERS. A smallish pied woodpecker, very similar to Fulvous-breasted Pied (845), also with crimson crown and crest in male, black in female. Barely distinguishable from it in the field by its whiter sides of head and neck and more boldly black-streaked underparts. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Khasi and Cachar hills, Nagaland (?), and hills of eastern Manipur; up to c. 2000 m. Probably also Mizo and East Pakistan hill tracts. Affects open pine and oak forest, and stunted trees on mountainsides and ridges.

Extralimital. Chin Hills, Arakan Yomas, Karen hills, S. Shan States, Tenasserim, N. Thailand and Laos (Peters). In the Mt Victoria region ranges between 1400 and 2800 m altitude; much commoner above 2000 m than below (Heinrich).

GENERAL HABITS. Typical woodpecker. Very similar to *P. auriceps* (842).

FOOD. Chiefly insects and grubs of beetles etc.

VOICE and CALLS. A shrill descending whinny as characteristic of the small woodpeckers (Deignan). A curious creaking, grating sound (by ♂) very like that produced by two rough pieces of wood — trunks or branches of trees — when pressed by wind and rubbing slowly against each other (Hume).

BREEDING. Season, end March to early May. Nest, the typical woodpecker hole cut in a small tree standing in a cultivation clearing in forest, usually under 4 metres from the ground. Eggs, 4 or 5, white. Average size of 22 eggs 21.3 × 16.9 mm (Baker). A curious habit observed by Baker at one nest was of both male and female sitting on the eggs at the same time. How general this habit may be is not known.

222

PICIFORMES

black; middle of abdomen tinged with yellow, lower abdomen and under tail-coverts crimson-pink.

Female. Like male but without the golden yellow and crimson on occiput.

Young (immature) like female but duller and more grey below. Crown umber-brown, each feather centred with yellow.

STATUS, DISTRIBUTION and HABITAT. Resident, locally common. Baluchistan, and from the Afghan frontier and Chitral eastward along the Himalayas through Punjab, Kashmir, Himachal Pradesh, Garhwal and Kumaon to western Nepal (to c. 81°E.); from c. 700 to 3300 m in open dry and moist temperate and pine forest — partial to oaks, deciduous, and mixed stands.

Extralimital. NE. Afghanistan (Nuristan).

GENERAL HABITS. Typical woodpecker. Common at most west-Himalayan hill stations, freely frequenting gardens and orchards. A pair has been observed roosting nightly during September on top of a veranda pillar in a P.W.D. Rest House, and a single bird in a nest-box in a hill garden for several weeks in February. The curious habit of drilling sapsucker-like holes in horizontal rings round medium-sized tree-stems has been noted also in this species: cf. 812 and 836 (A. E. Osmaston, JBNHS 24: 364).

FOOD. Insects, caterpillars and grubs. Also considerable quantities of seeds of Chir pine (*Pinus longifolia*), and pulpy fruit, e.g. mulberry (*Morus*), pear, apricot, etc.

VOICE and CALLS. 'A peculiar rather shrill and long cry at short intervals, reminiscent of the alarm call of *Halcyon smyrnensis*' (Scully). 'Note resembles that of *Hypopitius hyperythrus*' (Magrath). 'Drums for considerable periods during March–April' (Desirée Proud).

BREEDING. Season, chiefly April and May, sometimes into June. Nest-hole mostly under 8 metres from the ground; occasionally higher. Eggs, normally 4, rarely 5, white. Average size of 50 eggs 23.4 × 17.4 mm (Baker). Both sexes feed the nest-young; other facets of breeding biology not recorded.

MUSEUM DIAGNOSIS. See keys to the Species and Subspecies, and Field Characters; for details of plumage Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	112–118	21–24	18–20	68–73 mm (Baker)

COLOURS OF BARE PARTS. Iris brown (♀) to crimson (ad. ♂). Bill bluish horny, darker on culmen, paler at base of lower mandible. Legs and feet dull greyish green.

843. *Picoides auriceps incognitus* (Scully)

Picus incognitus Scully, 1879, Stray Feathers 8: 246 (Valley of Nepal)

Dendrocopos auriceps conoveri Rand & Fleming, 1956, Fieldiana, Zool. 39: 1
(15 miles west of Tansen, West Nepal, 5500 ft alt.)
Baker, FBI No. 1370 (part), Vol. 4: 42

LOCAL NAMES. None recorded.

PICIFORMES

224

MUSEUM DIAGNOSIS. Very similar to *P. macei* (845); differs from it, sex for sex, in having the sides of the head and neck, chin, throat and foreneck more white, less fulvous. Underparts from throat to vent boldly streaked with black, with only a faint indication of barring on the flanks. Black band on hindneck and upper back usually broader.

Young (immature) of both sexes have the feathers of the crown black, tipped, with crimson.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	114–122	24–26	18–19	65–72 mm (Baker)

Weight ♂ ♀ c. 42–52 g (Hume).

COLOURS OF BARE PARTS. Iris brown (♀) to lac-red (♂). Bill greenish horny, darker on culmen and tip. Legs and feet dusky leaden or plumbeous green.

PICOIDES MACEI (Vieillot): FULVOUS-BREADED PIED WOODPECKER

Key to the Subspecies

- Breast faintly streaked; middle tail-feathers all black....*P. m. macei*
Breast boldly spotted; middle tail-feathers barred with white....
.....*P. m. endamanensis*

Baker, FBI No. 1368, Vol. 4: 39

Plate 61, fig. 10

LOCAL NAMES. None recorded.

SIZE. Bulbul —; length c. 19 cm (7½ in.).

FIELD CHARACTERS. A smallish pied woodpecker, with white-barred black back; bright crimson crown and crest in male, black in female. Very similar to Stripectus Pied (844), q.v.; confusion with it likely in the restricted Manipur area of Assam where both occur together. *Macei* has the throat and foreneck uniform pale rufous-brown and only the breast faintly black-streaked; *atratus* has the entire underparts, except chin, boldly striated with black.

STATUS, DISTRIBUTION and HABITAT. Resident. Common. The Himalayas from c. Murree eastward through Kashmir (?), Himachal Pradesh, U.P., Nepal, Sikkim, Bhutan and NEFA. Assam hills south of Brahmaputra R., Cachar, Nagaland, Manipur, Mizo, East Pakistan, W. Bengal, Orissa south to c. 18°N. lat. in northern Andhra (Sankrametta). Affects all types of open forest and wooded country, plain and hill, up to c. 2000 m altitude (recorded at c. 2800 m in Nepal — Proud).

WOODPECKERS

229

FIELD CHARACTERS. Broadly as of 849. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident. The lower Himalayas from Murree (Rawalpindi dist.) eastward through N. Punjab, Himachal Pradesh, Garhwal, Kumaon and Nepal; from the terai up to c. 1700 m. Affects openly wooded country and scattered trees in cultivation, in tropical dry- and moist-deciduous and subtropical pine forest biotope. Intergrades with *semicoronatus* (849) in Nepal.

GENERAL HABITS, FOOD, VOICE and CALLS. As in *P. n. hardwickii* (852), q.v.

BREEDING. Season, chiefly April-May. Nest and eggs (c/4 or 5) as in 849. MUSEUM DIAGNOSIS. See Key to the Subspecies. Upper back and innermost secondaries barred with white.

MEASUREMENTS	Wing	Bill (from feathers)	Tarsus	Tail
♂♂	85-89	17-18	14-15	40-47 mm
♀♀	84-94	17-18	14-15	42-50 mm (Biswas)

Weight (summer) 3 ♂♂ 20-24 g; 2 ♀♀ 21-22 g (GD); (spring) 1 ♀ 27 g (SA). COLOURS OF BARE PARTS. As in 849.

849. *Picoides canicapillus semicoronatus* (Malherbe)

Picus semicoronatus Malherbe, 1849 (1848-9), Bull. Soc. Nat. Moselle, 5e cahier: 22 in text (Himalayas = Darjeeling)

Dendrocoptes nanus gigantisculus Koelz, 1952, Jour. Zool. Soc. India 4: 44 (Mawryngkneng, Khasi Hills)
Baker, FBI No. 1376, Vol. 4: 49

LOCAL NAME. *Daaja gadaiya mibhārang* (Cachari).

SIZE. Sparrow —; length c. 14 cm (5½ in.).

FIELD CHARACTERS. A diminutive pied woodpecker.

Male. Above, forehead and crown ashy grey; short occipital crest scarlet, surrounded by black. A broad whitish supercilium from behind eye continued as a wide band down sides of neck. Upper back black; wings, lower back, and rump black broadly barred with white. Upper tail-coverts and two central pairs of rectrices black; lateral rectrices more or less barred with white. Below, chin and throat whitish streaked with ashy; rest of underparts fulvous-brown, streaked with black.

Female similar to male but scarlet of hindcrown replaced by black.

STATUS, DISTRIBUTION and HABITAT. Resident; fairly common. Nepal (where it intergrades with *mitchellii*) through Darjeeling dist., Sikkim, Bhutan and northern Assam (intergrading with *canicapillus* in Cachar and Nagaland); terai, duars, foothills and up to c. 1700 m — occasionally to 2000 m. Affects open oak forest and mixed secondary jungle.

GENERAL HABITS, FOOD, VOICE and CALLS. Very similar to *P. n. hardwickii* (852), q.v.

BREEDING. Season, chiefly April-May. Nest, a shaft c. 10 to 20 cm deep bored in a thin branch between c. 5 and 10 m up in open forest. Tiny

Baker, FBI No. 1381, Vol. 4: 53 (= *brunneiceps*)

LOCAL NAMES. None recorded.

SIZE. Sparrow —; length c. 13 cm (5 in.).

FIELD CHARACTERS. As of 852. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident. From Rawalpindi dist. in W. Pakistan (Kahuta, c. 73°27'E. — Whistler, JBNHS 22: 626) eastward through Uttar Pradesh, Rajasthan, Nepal terai, Bihar, W. Bengal and East Pakistan, south to Orissa; foothills, terai, and plains. Affects light secondary forest and groves of mango and other trees around cultivation.

GENERAL HABITS, FOOD, VOICE and CALLS. As in *P. n. hardwickii* (852), q.v.

BREEDING. Season, principally February to early April. Nest and eggs (c/3 or 2) as in 852.

MUSEUM DIAGNOSIS. See Key to the Subspecies. Differs from *P. n. hardwickii* (852), sex for sex, in being much paler overall with the crown almost yellowish brown; more white in upperparts, especially on upper tail-coverts; underparts paler with pale brown streaks.

MEASUREMENTS	Wing	Bill (from skull)	Tarsus	Tail

Baker, FBI No. 1380, Vol. 4: 52

LOCAL NAME. *Chitta switi padhi* (Telugu).

SIZE. Sparrow —; length c. 13 cm (5 in.).

230

PICIFORMES

entrance-hole, c. 3 to 4 cm in diameter, drilled mostly on the underside of sloping or horizontal branches. Eggs, 4 or 5, white, glossy, roundish ovals. Average size of 30 eggs 18.6 × 14.4 mm (Baker). Both sexes share in drilling the nest-hole, incubation, and tending the young. Period of incubation not definitely ascertained; believed by Baker to be 12 or 13 days.

MUSEUM DIAGNOSIS. See Key to the Subspecies. Upper back and central rectrices unbarred black, upper tail-coverts usually so; if any white present on latter, confined to a few feathers only.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	80-90	16-18	13-16	38-46 mm
♀♀	82-91	16-19	14-15	39-48 mm (Biswas)

Weight (spring) 1 ♀ 27 g — SA.

COLOURS OF BARE PARTS. Iris biscuit coloured or greyish brown ('reddish brown' — Biswas). Bill horny brown, plumbeous on c. basal two-thirds of lower mandible. Legs and feet olive-plumbeous; claws horny brown.

850. *Picoides canicapillus canicapillus* (Blyth)

Picus canicapillus Blyth, 1845 (after 12 July), Jour. Asiat. Soc. Bengal 14 (1): 197 (Arrakan; type from Ramree Island)
Baker, FBI No. 1379, Vol. 4: 51
Plate 61, fig. 3

LOCAL NAMES. *Daaja gadaiya kashiba*, *Daaja gadaiya mibhārang* (Cachari).

SIZE. Sparrow —; length c. 14 cm (5½ in.).

FIELD CHARACTERS. Broadly as of 849. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident. Manipur, Mizo, Tripura and East Pakistan (hill tracts); plains, foothills and up to c. 1700 m. Affects thin open forest in tropical semi-evergreen biotope.

Extralimital. Burma, Thailand and the Indochinese countries.

GENERAL HABITS, FOOD, VOICE and CALLS. Very similar to *P. n. hardwickii* (852), q.v.

BREEDING. Season (April-May), nest and eggs (c/4 or 5) as in 849.

MUSEUM DIAGNOSIS. See Key to the Subspecies. Differs from *semicoronatus* (849) in having the upper tail-coverts barred, and central rectrices spotted with white. Scarlet of occiput confined as a streak on either side as in *mitchellii* (848).

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	80-94	16-19	13-16	34-46 mm
♀♀	80-92	16-19	13-16	39-45 mm (once 49) (Biswas)

COLOURS OF BARE PARTS. As in 849.

232

PICIFORMES

FIELD CHARACTERS. A diminutive brown and white woodpecker.

Male. Upperparts barred dark brown and white; crown umber brown with a narrow scarlet streak on either side of occiput. A conspicuous broad white stripe from above eye down sides of neck. Below, brownish white streaked with blackish.

Female. Similar to male but lacking the scarlet streaks on sides of hindcrown.

STATUS, DISTRIBUTION and HABITAT. Resident; fairly common locally. All peninsular

India (excluding the range of *cinereigula* in the southwest) northward to the southern limit (undefined) of *nanus* in Gujarat: through Madhya Pradesh and east to Orissa. Intergrades with *nanus* in Saurashtra and over a large part of Madhya Pradesh and Orissa, and with *cinereigula* in Coorg dist., Mysore. Affects light deciduous and bamboo forest, secondary jungle, and groves of trees in and around cultivation; plains and foothills up to c. 1200 m.

GENERAL HABITS. Usually keeps in pairs, frequently in association with the roving bands of small insectivorous birds such as nuthatches, tits, flycatchers and warblers. Actions and behaviour very like a nuthatch, for which it may casually be mistaken. Partial to woody stems of shrubs close to the ground; also to slender overhanging branches and bare topmost twigs of tall forest trees. Hardly ever seen on large tree-trunks or boughs. Creeps actively along and around a twig like a nuthatch tapping energetically with the bill as it progresses, and hops or flits from one twig to another like a sparrow. Flight rather sparrow-like, lacking the characteristic bounds and undulations of its larger relatives. May often be seen sunning itself in the early morning on the topmost bare twigs of tall forest trees, clinging inert for long periods. Has been observed roosting at night in the crotch of a leafless upright twig in a small tree at an angle of c. 45°.

FOOD. Chiefly insects and grubs. Stomach analyses showed ants (*Crematogaster compressus*, *Oecophylla smaragdina*, *Crematogaster subnuda*), bees (*Apis florea*), weevils (*Torymus* spp.), various elatrids, caterpillars, and geometrid and buprestid larvae (Mason & Lefroy, 1912). Also eats pulp of fruits and berries (*Ficus* figs, *Buchanania latifolia* drupes) and of *Mimosa* flowers (*Madhuca indica*), and flower-nectar, e.g. of *Salmalia malabarica*, *Erythrina indica* and spp., and *Butea monosperma*. Often has pollen adhering to chin and forehead feathers suggesting its implication in cross-pollination.

VOICE and CALLS. An occasional feeble, mousy *click-r-r* (contact call?) while creeping along the twigs. A soft but far-carrying drumming, usually on a bare end-twig at the top of some large tree overlooking the surrounding jungle.

BREEDING. Season, February to July, chiefly March and April, varying locally. Nest, a tiny hole, under 3 cm in diameter, drilled in a small dead branch between 2 and 12 metres up, in open forest or a mango grove; it leads down 5 to 10 cm to a somewhat widened unlined egg-chamber. In horizontal branches the entrance-hole is placed on the underside. Eggs, 3 or 4, white, glossy, roundish ovals measuring c. 18 × 14 mm. Both sexes

WOODPECKERS

233

share in excavating the nest, incubation, and feeding the young. Incubation period undetermined.

MUSEUM DIAGNOSIS. See Key to the Subspecies; for details of plumage Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	74-80	14-16	13-15	33-40 mm
♀♀	75-81	14-16	13-15	34-40 mm (SA, BB)

Weight 1 ♀ 15 g (SA).

COLOURS OF BARE PARTS. Iris pale lemon-yellow; eyelids and circumorbital skin magenta. Bill horny grey, dusky on culmen; mouth greyish pink. Legs and feet dark slate or purplish brown; claws brown.

853. *Picoides nanus cinereigula* (Malherbe)

Picus cinereigula Malherbe, 1849, Rev. et Mag. Zool. (2), 1: 531

(Madras = Alleppy, Travancore)

Baker, FBI No. 1380 (part), Vol. 4: 52

LOCAL NAME. *Mārmākkoti* (for all woodpeckers — Malayalam).

SIZE. Sparrow —; length c. 13 cm (5 in.).

FIELD CHARACTERS. As for 852. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident; fairly common locally. From Coorg dist. in Mysore (where it intergrades with *hardwickii*) and the Nilgiris and Palnis, southward through Kerala. Affects secondary jungle in deciduous and semi-evergreen biotope; from plains level to c. 1200 m.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 852, q.v.

BREEDING. Season, January to March. Nest, eggs and breeding biology not specifically recorded; doubtless as in 852.

MUSEUM DIAGNOSIS. See Key to the Subspecies. Intermediate between *hardwickii* of peninsular India and *gymnophthalmus* of Ceylon: upperparts brown rather than black, but darker than in *hardwickii*; crown very dark; streaking below, though definite, is so fine and light that in some specimens the underparts appear almost unicolorous, dirty white.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	71-76	15-17	13-14	33-37 mm
♀♀	71-77	15-16	12-13	32-36 mm (SA, BB)

COLOURS OF BARE PARTS. As in 852.

854. *Picoides nanus gymnophthalmus* (Blyth)

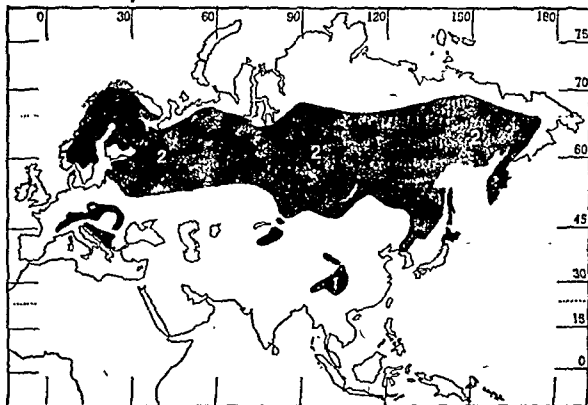

Picus gymnophthalmus Blyth, 1849, Jour. Asiat. Soc. Bengal 18 (2): 804 (Ceylon)

Baker, FBI No. 1382, Vol. 4: 54

LOCAL NAMES. *Māi kerellā*, *Chuti kerellā* (Sinhala); *Siru mārāmkotti* (Tamil).

WOODPECKERS

235

Picoides tridactylus

■ Breeding range
1 *P. t. funebris* (855).
2 Other Eurasian races (about 7) extralimital.

MEASUREMENTS

	Wing	Bill (from skull?)
3 ♂♂	130	31-33 mm
4 ♀♀	124-130	29-31 mm (Kinnear)

COLOURS OF BARE PARTS. Not recorded.

Genus HEMICIRCUS Swainson

Hemicircus Swainson, 1837, Classif. Bds. 2: 306

Type, by monotypy, *H. concretus* Pl. col. 90 = *Picus concretus* Temminck

Bill straight, laterally compressed towards tip; nasal ridge well marked, beginning at base about halfway between culmen and commissure and extending half the distance to tip; nostrils covered with plumes. Feet very large; hallux well developed; fourth toe longer than third. Tail very short, barely exceeding tail-coverts and only about one-third length of wing. Rectrices rounded at the end, the outer pair distinctly shorter than the rest.

The genus differs from all Indian woodpeckers in that the hyoid horns are curved round the right bulbous oculi. For a comparative study of the tongue of this and some other Indian woodpeckers see Steinbacher, J., 1934, Jour. f. Orn. 82(3): 359-408. Cf. Ali, Salim, 1951, IBNHS 49: 786.

234

PICIFORMES

SIZE. Sparrow —; length c. 13 cm (5 in.).

FIELD CHARACTERS. As of 852. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Subspecies endemic in Ceylon. Plentiful but locally distributed, throughout the lowlands and in the hills to over c. 1200 m. Affects secondary dry- and moist-deciduous jungle, neglected overgrown plantations, etc.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 852, q.v.

BREEDING. Season, February to June; occasionally in October and December (Phillips). Nest and eggs (c/2 or 3) as in *hardwickii*, the latter measuring c. 16 × 14 mm.

MUSEUM DIAGNOSIS. See Key to the Subspecies. Differs from *hardwickii* (852) in having the upperparts sooty black throughout (v. sooty brown), this difference particularly conspicuous on the crown. Underparts dirty white, faintly washed with yellowish fulvous and practically unstreaked.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	72-77	14-17	13-15	33-37 mm
♀♀	74-77	14-15	13-14	33-35 mm (Riwas)

Weight 1 ♂ 15 g; 1 ♀ 17 g (SDR).

COLOURS OF BARE PARTS. As in 852.

855. Threetoed Woodpecker. *Picoides tridactylus funebris* Verreaux

Picoides funebris J. Verreaux, 1870, Nouv. Arch. Mus. Hist. Nat. Paris, 6 Bull.: 33 (Mountains of Chinese Tibet = Sikang)

Not in Baker, FBI

Plate 61, fig. 7

LOCAL NAME. *Nakpo tungla* (Tibetan).

SIZE. Myna ±; length c. 23 cm (9 in.).

FIELD CHARACTERS. A medium-sized black and white woodpecker with no trace of crimson in the plumage, even in male. Above. Crown yellow in male, black in female; upperparts black with narrow broken white streaks. Below, chin, throat, foreneck to upper breast white; rest of underparts almost entirely black with small white flecks. Outer tail-feathers narrowly barred with white.

STATUS, DISTRIBUTION and HABITAT. Moderately common in conifer and deciduous forests in Kongbo and Takpo districts of SE. Tibet adjoining NEFA, therefore probably occurs also within our limits. Collected by Frank Ludlow at between c. 3300 and 4000 m, June to September (*Ibis* 1944: 369).

Extralimital. Western China in provinces of Kansu, Sikang, Szechuan and Yunnan (Peters).

GENERAL HABITS, FOOD, VOICE and CALLS. Tame and very silent. Has 'a low single note' (Ludlow).

BREEDING. Not recorded in our limits.

MUSEUM DIAGNOSIS. Toes only three. *Funebris* differs from all other subspecies of *P. tridactylus* in being much blacker, especially on the underparts.

236

PICIFORMES

856. Heartspotted Woodpecker. *Hemicircus canente canente* (Lesson)

Picus canente Lesson, 1830, Cent. Zool.: 215, pl. 73 (Pegu)

Picus cordatus Jerdon, 1840, Madras Jour. Lit. Sci. 11 (1): 211

(Forests of Malabar and in the Wynad)

Baker, FBI Nos. 1409, 1410, Vol. 4: 84, 85

Plate 61, fig. 4

LOCAL NAME. *Pülli mārāmkotti* (Malayalam).

SIZE. Sparrow +; length c. 16 cm (6½ in.).

FIELD CHARACTERS. A smallish, squat, black and buff woodpecker with short, very slender neck, large crested head, and a strikingly short and broad rounded tail.

Male. Above, forehead, crown, and crest black, the first two minutely speckled with white. Back black with a broad buff band on either side (wing-coverts and tertiaries) marked with heart-shaped black spots; rump buffy white. Below, chin, throat, foreneck and sides of neck buffy white; rest of underparts dusky olive and black.

Female similar to male but has the forehead and crown buffy white; crest black as in ♂.

Young (both sexes) like ♀ but much darker below, being, in the earlier stages, blackish brown or chocolate with no olive tinge.

STATUS, DISTRIBUTION and HABITAT. Resident; sparsely distributed, but locally not uncommon.

The Sahyadri or Western Ghats complex (including Nilgiri and Palni hills) from Kerala northward through Mysore, Goa and Maharashtra to the Tapi river (c. 21°N. lat., S. Gujarat) and Khandesh. Thence eastward across the forested hill tracts of Madhya Pradesh (the Satpura trend) through Chanda and Bastar districts, Orissa, W. Bengal, East Pakistan, Assam south of Brahmaputra river, and Manipur; plains, foothills and up to c. 1300 m. Affects moist-deciduous and secondary evergreen forest biotope. Partial to teak and bamboo jungle, and to shade trees in S. Indian coffee plantations.

Extralimital. Burma, Malay Peninsula, Thailand (chiefly lowlands of the eastern provinces) and southern Indochinese countries (Peters).

GENERAL HABITS. Keeps singly or in pairs, commonly amongst the mixed hunting parties of small insectivorous birds. Like the pygmy woodpeckers hunts on thin terminal branches up in tall trees rather than on the trunks and boughs. Creeps actively up, along, and around the twigs with jerky bobbing movements, very like some mechanical toy, tapping repeatedly with its bill here and there to dislodge insects from the cracks, occasionally digging into rotten wood with energy and determination. The constantly uttered squeaky calls give the first indication of its presence in a tree or grove. Commonly perches crosswise on twigs like a passerine bird, a habit which, combined with the large crested head, attenuated neck and stumpy

♀. × c. 1

WOODPECKERS

237

rounded tail identifies its silhouette a long way off. Flight weak and undulating, an exaggerated caricature of the characteristic bounding flight of the woodpecker family.

FOOD. Ants, termites, grubs, and other insects.

VOICE and CALLS. A squeaky chattering scream (or long drawn *chur-r*) frequently repeated. A characteristic rather pleasant — sharp but not loud — *tree, tree, tree*, sometimes strung out into a trill of 7 or 8 notes (Betts). A harsh jerky call somewhat like the wryneck's (SA). A thin, plaintive *su-rie* uttered with the head stiffly lowered and repeated 10 or 12 times, each *su-rie* accompanied by a bow or bob; a sharp double *ichlik-ichlik* given in flight (K. K. Neelakantan). The individual interpretation of these calls has not been attempted. Also recorded drumming during the breeding season.

BREEDING. Season, chiefly November to April. Nest, a tiny hole c. 3 to 4 cm in diameter drilled in a dead branch usually between 3 and 4 metres up, sometimes considerably higher. It passes obliquely downward to a depth of 15 or 20 cm or so, into a somewhat widened egg-chamber. Nests in Kerala recorded in rotting wooden fence-posts adjacent to a used plantation footpath 1 to 1.5 metres from the ground. Eggs 3, sometimes only 2, white, unmarked, measuring about 24 × 18 mm. Other facets of breeding biology not recorded.

MUSEUM DIAGNOSIS. There is no difference in coloration between birds from western India and the Assam-Burma population. There is, however, a continuous cline in size from south-west to north-east as shown by Salim Ali (loc. cit.), but no advantage is to be gained by upholding the smaller Kerala race *cordatus* hitherto recognized.

Both sexes have a tuft of bristly feathers in the middle of the back invariably clotted with a viscid resinous substance with a decidedly pleasant smell. The origin and purpose of this peculiar feature, which disappears in preserved skins, calls for investigation.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂♂	92-103	20-25	17-20	28-37 mm
♀♀	85-98	17-21	16-19	28-38 mm
		(from skull)		(SA, HW)

Weight 2 ♂♂ 35, 38 g; 1 ♀ 30 g (SA).

COLOURS OF BARE PARTS. Iris olive-brown. Bill dark horny brown; mouth greyish pink. Legs, feet and claws blackish slate or brownish black.

MISCELLANEOUS. Parasitized by tick *Haemaphysalis spinigera* (Rajagopalan, JBNHS 69: 62).

Genus BLYTHIPICUS Bonaparte

Blythipicus Bonaparte, 1854, *Ateneo Italiano* 2: 124. (Separately paged reprint, *Consp. Volucr.* Zygodact. 1854: 9.) Type, by subsequent designation, *Picus* (i.e. *Hemicircus*) *rubiginosus* Swainson

Bill long and stout, the culmen angulate and almost straight. Nasal ridge strongly developed, nearer to culmen than to commissure. Nostrils exposed. Chin angle about halfway between gape and tip of bill. Wing rounded: primaries just exceeding secondaries in length. Outer pair of rectrices longer than coverts. Hind toe well developed; fourth toe a little longer than third.

WOODPECKERS

239

strident *churra-cha-churra-cha-churra*”) uttered while flying agitatedly from tree-trunk to tree-trunk around the intruder, accompanied by an excited flicking of the wings on alighting.

BREEDING. Season, principally May and June. Nest, the typical woodpecker hole in a living or dead tree-trunk or stump in heavily wooded ravines etc., normally between 1 and 4 metres from the ground. Eggs 3, sometimes 2 or 4, white, long ovals. Average size of 25 eggs 29.7 × 21.2 mm (Baker). Both sexes take part in drilling the nest-hole, incubation, and feeding the young. Incubation period undetermined.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit. Breast in adult has a rusty wash, in juvenile dull earthy brown.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
		(from skull)		
♂♂	145-153	48-54	29-30	82-98 mm
♀♀	137-151	45-51	—	c. 82-85 mm
				(SA, BB, Stresemann)

Weight 1 ♂ 170 g; 1 ♀ 155 g (SA).

COLOURS OF BARE PARTS. Iris dull crimson; orbital skin olive-brown. Bill greenish yellow, more greenish at base of lower mandible. Legs and feet and claws horny brown.

Genus CHRYSOCOLAPTES Blyth

Chrysocolaptes Blyth, 1843, *Jour. Asiat. Soc. Bengal* 12 (2): 1004. Type, by subsequent designation, *C. strictus* = *Picus strictus* Horsfield

Bill long and straight. Nasal ridges strongly developed, commencing at base of bill and about half-way between commissure and culmen. Nostrils long and expanded. Feet exceptionally strong with the hallux well developed; claws long and strong. Outer tail-feathers slightly exceeding coverts in length.

CHRYSOCOLAPTES FESTIVUS (Boddaert): BLACKBACKED WOODPECKER

Key to the Subspecies

Larger and paler; forehead white; white centres of chest feathers more pronounced..... <i>C. f. festivus</i>
Smaller and darker; much more blackish on upperparts; black borders of feathers on lower parts broader..... <i>C. f. lentus</i>

858. *Chrysocolaptes festivus festivus* (Boddaert)

Picus festivus Boddaert, 1783, *Table Pl. enlum.*: 43 (Goa ex Daubenton, pl. 696) Baker, FBI No. 1403, Vol. 4: 77 Plate 60, fig. 12

LOCAL NAMES. None recorded.

238

PICIFORMES

857. Redeared Bay Woodpecker. *Blythipicus pyrrhotis pyrrhotis* (Hodgson)

Picus Pyrrhotis Hodgson, 1837, *Jour. Asiat. Soc. Bengal* 6: 108 (Nepal) *Blythipicus pyrrhotis porphyreus* Koelz, 1954, *Contrib. Inst. Regional Exploration*, No. 1: 23 (Nongpoh, Khasi Hills) *Blythipicus pyrrhotis pyrrhotipira* Koelz, 1954, *Contrib. Inst. Regional Exploration*, No. 1: 23 (Karong, Manipur) Baker, FBI No. 1383, Vol. 4: 55 Plate 62, fig. 13

LOCAL NAMES. *Fi-ing* (Lepcha); *Das gadaiya gojao* (Cachari).

SIZE. Pigeon —; length c. 27 cm (11½ in.).

FIELD CHARACTERS. A medium-sized barred rufous and black woodpecker with a prominent scarlet cross-band on nape extending to sides of neck behind the ear-coverts, and greenish yellow bill.

Female. Similar to male but without the scarlet nape-band. Could casually be mistaken for Rufous Woodpecker (803), but larger size, greenish yellow bill, and evergreen forest habitat diagnostic.

Young (immature). Underparts duller than in female, but everywhere faintly barred with rufous. Head, nape, and sides of neck blackish with broad chestnut median streaks.

× c. 1

STATUS, DISTRIBUTION and HABITAT. Resident. From central Nepal eastward through Sikkim, Bhutan and NEFA. Also Assam hills south of the Brahmaputra, Nagaland, Manipur, Mizo and East Pakistan (hill tracts); plains, duars, foothills and up to c. 2000 m. Affects dense evergreen climax forest and adjacent secondary jungle with bamboo.

Extralimital. Burma, northern Thailand, North Vietnam.

GENERAL HABITS. Almost always met with in pairs — rarely 3 or 4 together. Keeps fairly low down in bamboo thickets and undergrowth in dense forest, avoiding the open parts. Hops on the ground feeding among the roots and clinging to the bases of stems and decaying stumps, its presence usually betrayed only by its distinctive calls, or when flushed from the ground. Less commonly hunts also on higher trunks and branches.

FOOD. Mainly white ants, and beetle larvae.

VOICE and CALLS. An unmusical but not unpleasant *chake, chake, chake*, *chake* uttered slowly and deliberately four or five times, falling off in loudness as increasing in tempo towards the end. A loud chattering when flushed from undergrowth, *keret-keret-keret* (rendered by Smythies as a 'harsh

240

PICIFORMES

SIZE. Pigeon —; length c. 29 cm (12½ in.).

FIELD CHARACTERS. A medium-sized woodpecker rather like the Golden-backed (819) on a casual glimpse.

Male. Above, crown and crest crimson. Sides of hindneck white, running down to unite in a prominent white V on middle of upper back. Lower back and tail black. Upperparts of wings golden olive. Below, cheeks, chin, throat and foreneck fulvous-white with five narrow longitudinal black streaks. Rest of underparts buffy white, the feathers edged with black forming a bold scaly pattern on breast.

When only the head and neck of the bird are visible from behind a tree-trunk the 5-striped pattern on the white cheeks and throat (v. black streaked with white in Goldenbacked Woodpecker [819]) is diagnostic.

Female. Similar to male but crown and crest golden yellow instead of crimson.

STATUS, DISTRIBUTION and HABITAT. Resident; widely but sparsely distributed everywhere: practically all peninsular India with the exception of Sind, western Rajasthan, Kutch and most of Saurashtra in the west, and Assam and E. Pakistan in the east, thus roughly between longitudes 72° and 88°E., and south of latitude 28°N. Affects deciduous forest — low country and foothills with scrub and scattered trees.

GENERAL HABITS. Keeps singly or in pairs — sometimes trios (with the single young of the year?) — in open deciduous tree and bamboo forest. Feeds on tree-trunks as well as ground; partial to charred patches where the grass has been recently burnt. In non-breeding season roosts at night in disused nest-holes in tree-trunks, each bird occupying one of the several usually chiselled out one above the other 30 to 60 cm apart, in successive years. Whether the 'apartments' are occupied on an 'ownership' basis by birds themselves raised in the same hole, and whether the same individuals occupy the same hole night after night, are interesting points for investigation.

FOOD. Chiefly ants and grubs of wood-boring beetles.

VOICE and CALLS. A loud chattering 'laugh' similar to the Golden-back's, particularly to that of the Larger, *C. lucidus* (850-62), but different in timbre; the two confusable if heard independently and at different times. A rapidly repeated unmetallic *kuirri-rr-rr-rr* uttered in runs of 6 or 7 every few minutes (K. K. Neelakantan).

BREEDING. Season, overall November to March, varying locally. Nest, the typical woodpecker hole chiselled out in a tree stem between 2 and 7 metres from the ground. A fresh hole is excavated each year so that often four or more holes may be found in the same stem one above the other in apartment-house fashion, though only the latest is occupied for nesting.

WOODPECKERS

241

Holes usually distinctive — pear- or 'horse-collar'-shaped rather than circular as in most woodpeckers, measuring c. 11×8 cm in diameter and 25–30 cm deep. Eggs, normally a singleton, rarely 2, white, unmarked. Average size of 5 eggs 31.2×24.1 mm. Both sexes share in excavating the hole and all other domestic chores. Incubation period undetermined.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

Young (immature). Crown and crest flame-coloured in male; black, spotted with white in female.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	152–162	44–54	30–31	72–85 mm
♀♀	149–158	43–51	26–30	72–81 mm (SA, HW)

COLOURS OF BARE PARTS. Iris creamy orange to crimson (brown in young birds); circumorbital skin pale flesh colour. Bill slaty or brownish black. Legs and feet greenish plumbeous; claws horny brown.

859. *Chrysocolaptes festus tantus* Ripley

Chrysocolaptes festus tantus Ripley, 1946, *Spolia Zeylanica* 24: 214
(Embilipitiya, Ceylon)

Baker, FBI No. 1403 (part), Vol. 4: 77

LOCAL NAMES. *Māhā-rāṅg kērellā* (Sinhala); *Mārāmkottī, Thāchchan kūrūrī* (Tamil).

SIZE. Pigeon —; length c. 29 cm ($12\frac{1}{2}$ in.).

FIELD CHARACTERS. As for 858. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Subspecies endemic in Ceylon. Locally distributed in small numbers, in a few well-wooded areas in the North Central Province in the northern half of the island, and in the Hambantota and Embilipitiya districts of the Southern Province (Phillips).

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 858, q.v.

BREEDING. Season, January to March; occasionally in September. Nest, frequently drilled in decaying trunks of coconut palms near villages, and eggs (c) 1 or 2 as in 858.

MUSEUM DIAGNOSIS. Differs from the Indian population (858) in being smaller and darker. Black stripes on chin and throat noticeably broader, as are also the black borders to the feathers on breast and abdomen.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
1 ♂	150	52	29	75 mm
2 ♀♀	144, 147	49 (1) (from feathers) 43 (1)	28 (1)	76, 79 mm (HW, SDR)

Baker, FBI No. 1404, Vol. 4: 78

Plate 60, fig. 17

LOCAL NAMES. *Tashi-on-bau* (Lepcha); *Dauja gadaiya* (Cachari).

SIZE. Pigeon; length c. 33 cm (13 in.).

FIELD CHARACTERS. A medium-sized goldenbacked woodpecker.

Male. Above, crown and crest crimson; nape and hindneck white. Back and mantle golden olive; rump crimson; upper tail-coverts and tail black. Below, buffy white as in *festus* (858) but with foreneck and breast very dark, the scaly pattern looking more like white spots on a black background. Cheeks and chin white; two black stripes on either cheek meeting on sides of throat and continuing; a fifth broader black stripe down centre of chin and foreneck (see figure).

♂, x c. 1

Female similar to male but with the crown and crest black, stippled with white.

Casually confusable, sex for sex, with Himalayan Threetoed Goldenback (824), but different pattern of the black throat-stripes diagnostic, q.v.

Young (immature) has crown and crest as in female, the male first acquiring the crimson occipital crest and later the crimson crown.

STATUS, DISTRIBUTION AND HABITAT. Resident; fairly common in the appropriate biotope. East-central Nepal eastward through Sikkim, Bhutan, NEFA and Assam; Nagaland, Manipur, Mizo, East Pakistan, W. Bengal, Bihar, Orissa, eastern Andhra (Vaisakhapatnam Ghats); south to Bastar dist. in eastern Madhya Pradesh. Affects well-wooded moist-deciduous and semi-evergreen forest areas, especially in broken foothills country; chiefly below c. 700 m, sparingly up to 1600 m.

Extralimital. Burma, Shan States, Thailand south to the Lankawi Islands; S. Vietnam.

GENERAL HABITS. Typical woodpecker. Keeps in noisy pairs, occasionally family parties, flying swiftly from tree to tree with the characteristic

242

PICIFORMES

CHRYSOCLAPTES LUCIDUS (Scopoli): LARGER GOLDENBACKED WOODPECKER

Whistler has drawn attention to the fact that in this species the top of the bill has on each side, between the nasal groove and the culmen ridge, a series of fine transverse ridges closely resembling the match-striker found on old-fashioned silver match-boxes. The function of this feature needs investigation.

Key to the Subspecies

COLOURS OF BARE PARTS. As in 861.

PICIFORMES

244

bounds and undulations, alighting low on a trunk and working upwards in jerky spurts and spirals. Seldom, if ever, feeds on the ground. Very agile in dodging behind tree-trunks to escape observation, and could thus be easily missed unless first seen alighting. Usually shows no more of itself from behind the stem than the head and neck, when the pattern of the stripes on cheeks and foreneck is a useful pointer to its identity. A pair has been observed hawking winged termites in company with drongos, launching out in the air, hovering like a Pied Kingfisher clumsily, making half a dozen captures in the bill and returning to the tree (Hume quoting Capt. Fielden, SF 3: 64–5).

FOOD. Insects, grubs, etc. Also nectar, e.g. of *Salmaia* and *Erythrina* flowers, as a subsidiary item.

VOICE AND CALLS. A discordant trilling 'laugh' or scream, rather like that of the commoner Goldenbacked Woodpecker (819) but shriller and more 'tinny', uttered chiefly in flight. Also drums energetically in the breeding season.

BREEDING. Season, chiefly March to May. Nest, the typical woodpecker hole in a tree-trunk, vertically oval in shape rather than circular, 2 to 5 metres up, in practically every type of wooded country — mango groves near villages or within humid forest. The same cavity is often used for many successive years, with fresh entrances cut each time all leading to the same chamber, but whether by the same or other birds is not known. Eggs, 4 or 5, white, unmarked. Average size of 40 eggs 30.0×22.1 mm (Baker). Period of incubation, *vide* Baker, 14 to 15 days, and fledging period 24 to 26 days.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit. Differs from West Himalayan *sultaneus* (860) in being slightly smaller with a comparatively smaller bill.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂♀	157–178	43–56 (from skull)	30–31	85–97 mm (Baker)
4 ♂♂	165–172	48–50	31–33	90–97 mm
4 ♀♀	168–173	47–49	31–32	83–90 mm (SA)

COLOURS OF BARE PARTS. Iris creamy orange or fawn colour. Bill horny brown or black, plumbeous at gape and base of lower mandible. Legs and feet greenish plumbeous; claws horny brown.

862. *Chrysocolaptes lucidus chersonesus* Kloss

Chrysocolaptes strictus chersonesus Kloss, 1918, *Ibis* 113 (Johore, Malaya)
Chrysocolaptes guttaeristatus socialis Koels, 1939, *Proc. Biol. Soc. Washington* 52: 78
(Jabalbad, Bombay Presidency)
Baker, FBI No. 1406, Vol. 4: 80

LOCAL NAMES. For woodpeckers in general: *Mārāmkottī* (Malayalam); *Thāchchan kūrūrī* (Tamil).

WOODPECKERS

245

SIZE. Pigeon \pm ; length c. 31 cm (12½ in.).

FIELD CHARACTERS. As of 861. See Museum Diagnosis.

May be confused with the superficially similar Threetoed Woodpecker (825)—also crimsonbacked—but the slightly larger size, white hindneck (v. black), and distinctive cheek markings will distinguish this bird.

STATUS, DISTRIBUTION and HABITAT. Resident; not uncommon in the appropriate biotope. Kerala and northward along the Western Ghats complex (including the Nilgiri and Palni hills) through Mysore, Goa, Maharashtra and Gujarat to the Tapi river, and Khandesh; from plains level up to c. 1800 m. Affects evergreen and moist-deciduous biotope; partial to scrub and mixed secondary jungle in the moist intermediate zone; rare or absent in the coastal belt.

EXTRALIMITAL. Extreme southern part of Malay Peninsula, Singapore island, Riau Archipelago, Sumatra, western and central Java (Peters).

This is one more example (cf. Great Pied Hornbill [776]) of the fact that birds of the same species at the extremities of the 'Indo-Malayan horseshoe', i.e. Ceylon-India-Burma-Malaya, are closely alike.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 861, q.v. Has been observed roosting at night on a bare branch at an angle of 45° to the trunk, squatted along it as when searching for food, but completely 'frozen'.

BREEDING. Season, overall December to March. Nest, similar to that of Blackbacked Woodpecker (858), a pear-shaped or vertically oval hole c. 8 cm wide in a tree-trunk at heights between 2 and 20 metres, running in horizontally at first, then turning to vertical for 30 cm or so and ending in a slightly bulbous chamber. The lower edge of the entrance-hole is usually bevelled off into a slope. Eggs, normally a singleton, very rarely 2, white, unmarked, measuring c. 28 × 20 mm.

MUSEUM DIAGNOSIS. Differs from *guttacristatus* (861) in being somewhat smaller, with the upperparts more olive, less golden, making them appear decidedly darker. The crimson of the rump usually extends slightly further up the back.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	149-158	42-52	30-31	77-91 mm
♀♀	147-157	41-50	27-30	80-89 mm (SA, HW)

Weight 2 ♀♀ 163, 164 g (SA).

COLOURS OF BARE PARTS. Iris cream colour with a pinkish tinge (more precisely, a fine outer ring reddish, inner ring pinkish cream colour). Bill dark horny brown, plumbeous at chin; mouth slaty pink. Legs and feet greyish green or greenish plumbeous; claws dark horny brown.

863. *Chrysocolaptes lucidus stricklandi* (Layard)

Brachypterus Stricklandi Layard, 1854 (June), Ann. Mag. Nat. Hist. 13 (3): 449 (Gillymale, Ceylon)

Indopicus Carlotta Malherbe, 1854 (July), Rév. et Mag. de Zool., ser. 2, 6: 379 (Ceylon)

Baker, FBI No. 1407, Vol. 4: 81
Plate 60, fig. 18

LOCAL NAMES. For woodpeckers in general: *Mikālāṅ kērellā* (Sinhala); *Mārām-kētti*, *Thachchen kētti* (Tamil).

BROADBILLS

247

the shafts. Rictal bristles present. Bill broad and flat, comparatively small, with sides of upper mandible straight, not overhanging near gape. Nostrils rounded, exposed, at base of culmen. Scutellation of tarsus in front almost obsolete; inside of tarsus covered with an undivided lamina. Sexually dimorphic.

864. Collared Broadbill. *Serilophus lunatus rubropygius* (Hodgson)

Raja Rubropygia Hodgson, 1839, Jour. Asiat. Soc. Bengal 8: 36 (No locality = Nepal)
Baker, FBI No. 1334, Vol. 3: 470

Plate 63, fig. 3

LOCAL NAMES. *Kāi sīyā* (Nepali); *Reb kyul* (Lepcha); *Das hungari* (Cachari).

SIZE. Bulbul \pm ; length c. 19 cm (7½ in.).

FIELD CHARACTERS. A sluggish arboreal ashy grey bird with a short recumbent crest overhanging the nape. Lower back chestnut. Wings black with contrasting chestnut, blue, and white markings. Tail black, graduated, the lateral rectrices white-tipped. Prominent yellow skin around eye.

Female. Similar to male, but with a demi-gorget of white-tipped feathers on either side of neck.

STATUS, DISTRIBUTION and HABITAT. Resident; Nepal eastward through Bhutan and

NEFA, Assam, Nagaland, Manipur, Mizo and East Pakistan (hill tracts): terai, plains, foothills and up to c. 1700 m. In tropical semi-evergreen and evergreen biotope. Affects sal and mixed secondary tree and bamboo jungle.

EXTRALIMITAL. Arakan, Chin Hills, and northern and western Burma.

GENERAL HABITS. Arboreal and somewhat crepuscular. Keeps in parties of 5 to 20 or so to the better wooded parts, the individuals loosely together. Very active in the morning and at dusk, but also hunts lethargically during the day. Tame and confiding to the point of stupidity, even after being fired at. Perches very erect, the tail kept well down and frequently twitched. Takes insects off the branches and foliage of trees in clumsy but agile fluttering sallies. Bounces lightly from branch to branch using the wings as a parachute—an action reminiscent of the Common Wood Shrike.

FOOD. Grasshoppers, mantises and other insects. Tiny land shells have been found crammed in a stomach dissected.

VOICE and CALLS. A soft rather musical whistle, and a low *chir-r-r-r* uttered both at rest and in flight have been described. Also a loud mouse-like squeaking when alarmed.

BREEDING. Season, March to May or June. Nest, a bulky untidy ball c. 15 cm in diameter of coarse grass, weeds or moss bound together with black hair-like roots, with a round lateral entrance c. 5 cm across overhung by a porch—rather like an enlarged sunbird's nest. Lined with broad bamboo or grass leaves or draped on the exterior with spiders' egg-cases

♀, x c. 1

PASSERIFORMES

246

SIZE. Myna \pm ; length c. 29 cm (11½ in.).

FIELD CHARACTERS. As of 861, sex for sex, but with entire back crimson instead of rump only. See Museum Diagnosis.

May be confused with the superficially similar Redbacked Woodpecker (823); distinguishable from it by the deeper crimson back and wings, longer and paler coloured bill, and more high-pitched and tinny call-note.

STATUS, DISTRIBUTION and HABITAT. Subspecies endemic in Ceylon. Moderately plentiful, but locally distributed, throughout the forests and well-wooded areas of the lowlands and hills to over 2100 m (Phillips).

GENERAL HABITS, FOOD, VOICE and CALLS. As in 861, q.v.

BREEDING. Season, October to April; chiefly December and January. Nest and eggs (c/1 to 3) as in 861.

MUSEUM DIAGNOSIS. Differs from *guttacristatus* (861) and *chersonesus* (862) in having the whole back crimson (v. rump only), and the wings rather duller crimson instead of golden or olive-yellow. The black on the head is greater in extent, and the white less.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂♀	142-150	42-45 (from feathers)	30-31	90-95 mm (Baker)
4 ♂♂	145-149	46-49	27-30	80-83 mm
3 ♀♀	148	45-47 (from skull)	27-28	79-82 mm (HW)

Weight 1 ♀ 138 g (SDR).

COLOURS OF BARE PARTS. Iris yellowish white, yellow, buff, or buff with an outer reddish ring. Bill horny brown or plumbeous brown at base, paling towards tip where it is almost white and tinged with green in the centre. Legs and feet dull greenish brown or greenish slate (Baker).

Order PASSERIFORMES

For morphology and characters see Stressemann, E., 1927-34, *Acer*: 843-4; Baker, E. C. S., 1922, FBI 1: 10-17; for general account Thomson, A. L. (ed.), 1964, *New Dict. Birds*, London and New York (Article 'Passeriformes'). In almost all Passeriformes the order of wing (primaries) moult is strictly descending. This widespread mode seems to be primitive (Stressemann).

Family EURYLAIMIDAE: Broadbills

For description see Van Tyne, J. and Berger, A. J., 1959: 486; Baker, E. C. S., 1926, FBI 3: 459-60; Mackworth-Praed, C. W., 1964, Article 'Broadbill' in Thomson, A. L. (ed.) *New Dict. Birds*, London and New York.

Key to the Indian Genera

	Page
Tail shorter than wing.....	<i>Serilophus</i> 246
Tail longer than wing.....	<i>Psarisomus</i> 248

Genus SERILOPHUS Swainson

Serilophus Swainson, 1837, *Classif. Birds* 2: 262. Type, by monotypy, '*S. lunatus* Zool. Tr. 1, pl. 25' = *Eurylaimus lunatus* Gould

Plumage very soft and lax. Tail much graduated. Wings rounded, much longer than tail. Secondaries and inner primaries truncated and emarginate at the ends of

248

PASSERIFORMES

etc., an untidy 'beard' of loose material dangling below. Suspended by a slender attachment from a branch or bamboo twig, normally 2 to 4 metres up, almost invariably overhanging some trickle or pool in a ravine; usually quite conspicuous. Eggs normally 5, sometimes 4, white tinged with pale creamy pink or claret; usually speckled with minute reddish brown or purplish black dots, more densely at the broad end. Average size of 100 eggs 23.6 × 17.3 mm (Baker). Both sexes partake in building the nest, incubation, and feeding the young. Incubation period undetermined.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

Young (immature) described from a single juvenile as similar to adult but chestnut of rump extending further up on to mantle; grey of head and hindneck also faintly washed with chestnut; silvery white marks on sides of neck indicated, but less broad and clear (Garthwaite & Ticehurst, JBNHS 39: 559).

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂♀	83-88	(from skull) 15-17	c. 21	66-71 mm (SDR, SA)

Weight (winter) 2 ♀♀ 33, 35 g (SDR).

COLOURS OF BARE PARTS. Iris brown; orbital skin bright yellow. Bill: upper mandible blue with pale edges and tip; lower mandible blue at base, yellowish green on gony. Legs and feet bright yellowish green; claws plumbeous.

Genus PSARISOMUS Swainson

Psarisomus Swainson, 1837, *Classif. Birds* 2: 261. Type, by monotypy, '*P. dalhousiae* Wilson, Ill. Zool.' = *Eurylaimus dalhousiae* Jameson

Bill broad and flat; edge of upper mandible straight, not overhanging. No rictal bristles, but oral feathers directed forward. Tail longer than wing; steeply graduated, the outermost feathers being about one-third the length of the middle. Wing rounded; 3rd or 4th primary (as.) longest. Scutellations of tarsus indistinct on outer front, obsolete on inside. Sexes alike.

865. Longtailed Broadbill. *Psarisomus dalhousiae dalhousiae* (Jameson)

Eurylaimus dalhousiae Jameson, 1835, *Edinburgh New Philos. Jour.* 18: 589 (Northern India, probably near Simla)

Baker, FBI No. 1335, Vol. 3: 472

Plate 63, fig. 1

LOCAL NAMES. *Rāi-i* (Nepal); *Dang-mo-mith*, *Dang-rat-pho* (Lepcha); *Das hungari raja* (Cachari).

SIZE. Bulbul \pm ; length c. 27 cm (10½ in.).

FIELD CHARACTERS. A showy grass-green arboreal bird with a longish graduated tail largely bright blue above, black below. Bright yellow chin and throat produced up sides of neck as a collar broken behind. Crown black with an oblong yellow spot on either side, and a bright blue patch in the centre. A white patch on the black underside of wings prominent in flight. Sexes alike.

BROADBILLS

249

Young (immature) like adult, but has no blue on head, and chin and throat greenish yellow.

x c. 1

STATUS, DISTRIBUTION and HABITAT. Resident, subject to seasonal local movements. The Himalayas from Garhwal (Mussooree) through Kumaon, Nepal, Sikkim, Bhutan and NEFA; south through Assam, Nagaland, Manipur, Mizo and East Pakistan (hill tracts); in tropical and subtropical evergreen biotope from terai and plains level to c. 2000 m. Affects

mixed forest and secondary growth with bamboo, riverain jungle, etc.

Extratropical. Burma, Thailand and the Indochinese countries. The species extends to Malaysia, Sumatra and Borneo.

GENERAL HABITS. Arboreal and sociable. Keeps in flocks of 15 to 30, moving about in the foliage canopy or middle storey in forest in sprawling follow-my-leader style from tree to tree. Flight-silhouette when overhead, as well as upright stance when perched, and habit of fluttering in front of sprigs to take insects and spiders, very reminiscent of the minivets (*Pericrocotus*), though actions more sluggish. When perched upright switches tail like a shrike. Often launches out to take a winged insect in the air, flying on to another perch after the capture. Like the Collared Broadbill is stupidly tame and trusting even after being fired at and several of the flock killed. Close hunting association with Haircrested and other drongos has been frequently observed, the drongos swooping upon any moths or other winged insects flushed from the foliage by the fluttering broadbills.

FOOD. Large black ants, bugs (Hemiptera), green grasshoppers and other orthopterous insects, and spiders.

VOICE and CALLS. A distinct loud sharp whistle *tsay, tsay, tsay* repeated continuously 5 to 8 times with little change in pitch, usually in flight. Silent while feeding except for an occasional single note *tsay* or *tswee*.

BREEDING. Season, April-May-June. Nest, a well-made pear-shaped pouch of bamboo leaves, grass, roots, moss and creeper stems, etc. with a ragged 'beard' of loose material hanging from the bottom, and decorated on the outside with spiders' egg-cases, scraps of green moss, etc. Overall length including suspension and beard c. 1 metre; size of globe containing egg-chamber c. 25 x 15 cm. Suspended by a thin plant attachment from branches usually overhanging wooded ravines, 2 to 10 metres from the ground. Telegraph lines spanning forested nullahs appear to be favourite sites, the nest being suspended well out along the open wire, away from any vegetation, and very conspicuous. Eggs, 5 or 6, variable in coloration — white to salmon-pink blotched with pale brick-red, brick-pink, or deep rich red-brown, and secondary lilac-grey markings. Average size of 200 eggs 27.4 x 19.4 mm (Baker). Both sexes take part in building the nest, incubation, and evidently also in feeding the young. Incubation period undetermined.

PITTAS

251

In low cross-flight from one thicket to another, silhouette very like a waterhen's (*Amaurornis*).

STATUS, DISTRIBUTION and HABITAT. Resident, subject to seasonal dispersal movements, largely altitudinal. Central Nepal eastward through Sikkim, W. Bengal (Darjeeling dist.), Bhutan and NEFA. Assam, Nagaland, Manipur, Mizo, and East Pakistan (hill tracts). From plains level and duars up to c. 2000 m. Affects tropical and subtropical secondary evergreen and bamboo jungle, and densely overgrown clearings.

Extratropical. Arakan Yomas, northern Burma, North Vietnam.

GENERAL HABITS. Almost entirely terrestrial, and a great skulker. Keeps singly or in separated pairs in dense shrubbery, flicking aside the fallen leaves or digging into the mulch with its stout bill for food. Progresses on the ground in swift long hops, like a rat in a hurry, and on a fleeting glimpse could easily be mistaken for one. Ventures on to the edge of forest paths etc. in the early mornings and at dusk, withdrawing precipitately into the undergrowth on alarm.

FOOD. Ants, beetles, and other insects, grubs, worms, lizards and various small animals.

VOICE and CALLS. 'A magnificent double whistle, uttered both on the ground and when on a tree, most often in the early mornings and late evenings' (Baker). Baker also records 'a very soft chuckle' between a feeding pair.

BREEDING. Season, April to August, chiefly May and June. Nest, a large oblong domed structure like a Rugby football in shape, of loosely put-together bamboo leaves, coarse roots and grass, with entrance at one end. Placed on the ground in the base of a bamboo clump or other dense bush; sometimes a couple of metres or so up in the forking branch of a tree. Eggs, normally 4, sometimes 5 or even 6; rather spherical, glossy china white sparingly spotted with primary markings of reddish brown and secondary ones of lilac or lavender-grey. Average size of 100 eggs 29.5 x 22.4 mm (Baker). Both sexes share in building the nest, incubation, and feeding the young. Incubation period undetermined.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit. Underparts considerably variable in depth of coloration in male, some individuals having a beautiful fulvous-pink flush on throat and foreneck. Many, but not all, Assam and Manipur birds have black centres to the scapulars and feathers of back, rump and upper tail-coverts, absent in topotypical birds from Nepal and Sikkim.

Nesting. Above, dark brown, each feather with a large central patch of pale fulvous and blackish edges. Below, very pale fulvous-pink, the feathers of chin, throat, and foreneck with obsolete dark edges. Feathers of rest of underparts with black bases and narrow black borders, the former showing everywhere but most boldly on breast and flanks (Baker).

MEASUREMENTS	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	116-129	22-26	51-59	61-68 mm (Baker)
		(from skull)

PASSERIFORMES

MUSEUM DIAGNOSIS

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂ ♂	103-116	21-23	28-30	116-132 mm
♀ ♀	96-105	21-24	28-30	116-127 mm (BB, SA)

The apparent sexual dimorphism in wing-length can be verified only by measuring many more correctly sexed specimens.

Weight 1 ♀ (winter) 67 g (SDR).

COLOURS OF BARE PARTS. Iris brown or khaki; fine circumorbital rim greenish yellow. Bill sage-green: upper mandible bluish at gape; underside of lower mandible pinkish orange at chin and basal two-thirds, bluish green at tip. Legs and feet sage-green; claws horny brown.

Family PITTIDAE: Pittas

For description see Van Tyne, J., and Berger, A. J., 1959: 497; Baker, E. C. S., 1926, FBI 3: 441; Mackworth-Fraser, C. W., 1964, Article 'Pitta' in Thomson, A. L. (ed.), *New Dict. Birds*, London & New York.

Genus PITTA Vieillot

Pitta Vieillot, 1816, Anal. nouv. orn.: 42. Type, by subsequent designation, *Corvus brachyurus* Linnaeus

Wing with ten primaries, the first (as.) very long and reaching almost to tip of wing. Tail of twelve feathers, very short; feathers of crown very full and erectile, forming a short thick crest, not apparent unless the bird is excited. Tarsus exceptionally long and strong, the anterior surface entire and smooth.

866. Bluenaped Pitta. *Pitta nipalensis nipalensis* (Hodgson)

Paludicola nipalensis Hodgson, 1837, Jour. Asiat. Soc. Bengal 6: 103 (Nepal)

Baker, FBI No. 1317, Vol. 3: 444

Plate 63, fig. 10

LOCAL NAME. *Dao hui yegashi* (Cachari).

SIZE. Quail +; length c. 25 cm (10 in.).

FIELD CHARACTERS. A dumpy stub-tailed terrestrial bird, largely blue and greenish brown above, plain fulvous below. Nape and hindneck bright blue; tail brown tinged with green.

Female. Above, similar to male but hindcrown rufous-fulvous instead of blue, and hindneck green. Below, like male but throat usually more whitish.

252

PASSERIFORMES

COLOURS OF BARE PARTS. Iris brown; eyerim pale salmon. Bill horny brown, paler at tip. Legs and feet brownish flesh; claws paler.

867. Indian Pitta. *Pitta brachyura brachyura* (Linnaeus)

Corvus brachyurus Linnaeus, 1766, Syst. Nat., ed. 12, 1: 158 (Moluccas = Ceylon)

— *Pitta brachyura pulchra* Koelz, 1939, Proc. Biol. Soc. Washington 52: 77

(Bhadwar, Kangra, Punjab)

Baker, FBI No. 1323, Vol. 3: 453

Plate 63, fig. 12

LOCAL NAMES. *Noorāng* (Hindi); *Shumcha* (Bengal); *Polānki pitta* (Telugu); *Anu-māni kūriri*, *Thōūd kālān*, *Kāhūlūchi* (Tamil); *Kāvi* (Malayalam); *Avichhiya* (Sinhala); *Dao hui yegashi* (Cachari).

SIZE. Quail ±; length c. 19 cm (7½ in.).

FIELD CHARACTERS. A gaudily coloured stub-tailed thrushlike terrestrial bird — green, bright blue, black, white and fulvous with crimson-pink abdomen, vent, and under tail-coverts. In flight a round white patch near tip of wings conspicuous. Sexes alike.

Young (immature) has the crown darker, the feathers edged with black; back very dark, much duller and browner than in adult; underparts duller and browner with but little pink on belly and vent.

STATUS, DISTRIBUTION and HABITAT. Resident, with far-ranging seasonal migratory and dispersal movements not properly worked out. Practically the entire subcontinent including Assam, Manipur and East Pakistan, from the sub-Himalayas to Kanyakumari (excluding Sind and the more arid parts of Rajasthan); low country and foothills, occasionally up to 1700 m. Breeds over a wide area in northern and central India from about Kangra (Punjab) in the west to Cachar (Assam); sporadically elsewhere, e.g. Gir forest (Saurashtra) and Bombay environs. Mainly an abundant southwest monsoon or winter visitor and/or passage migrant in peninsular India. Winter visitor also to Ceylon from c. October to March-April. Affects scrub jungle, semi-cultivation and patches of light deciduous and evergreen forest. One unprecedented sight record near Islamabad, Pakistan, 17.vi.1978 (JBNS 75: 924-5).

MIGRATION. Vast numbers are observed on regular passage all about the same time but not in flocks every year — locally almost to the date — through south and peninsular India northward in May and June, heralding the advance of the SW. monsoon; in the opposite direction, towards Ceylon, in September-October marking the end of the rainy season. Details of the movements have not yet been studied.

GENERAL HABITS. Mainly terrestrial, but roosts in low trees. Hops about on the ground like a thrush, rummaging amongst the dead leaves and digging into the wet earth with the bill for insects and grubs. On disturbance flies up into a branch with a whirr of wings, sitting motionless, only the stumpy tail wagging very slowly and deliberately up and down like some mechanical toy.

FOOD. Insects, grubs and worms. In the neighbourhood of villages commonly fly maggots pecked out from human excreta.

VOICE and CALLS. A loud clear double whistle *wheet-tlee* or *wheet-pyeen* uttered mostly in the early morning and late evening; throughout the day

PITTAS

253

in cloudy overcast weather. The calling bird pulls itself upright and jerks its head well back as when swallowing water; it is jerked forward again with the concluding *tiu*—an action altogether very like the crowing of a cock. The calls are repeated at the rate of 3 or 4 in 10 seconds, and sometimes kept up for 5 minutes or more at a stretch, several birds answering one another in the distance. A variant of this call is a single long-drawn *whewer*, similarly answered by others. Has, in addition, several harsh monosyllabic *chers* and *meus*.

BREEDING. *Season*, May to August. *Nest*, a large globular structure, c. 20 cm long × 15 cm wide, of twigs, roots, grass, etc. with the entrance at one end. It is placed in the forked branch of a small tree usually between 3 and 4, but sometimes even 8 or 9 metres from the ground; rarely on the ground itself in scrub jungle, under shelter of a bush. *Eggs* 4 to 6, glossy china white with sparse spots, specks and occasionally fine hair lines of dull or dark purple. Average size of 50 eggs 24.7 × 21.2 mm (Baker). Both sexes evidently take part in all the domestic chores. Incubation period undetermined.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit. Undergoes complete post-nuptial moult in August-September; has no spring moult.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂ ♀	101-111	22-26 (from skull)	35-39	36-40 mm (Baker, SA, HW)

Weight 2 ♂♂ 57, 65 g (Kensch); 25 ♂♂ 47-66 g (aver. 55.5) — SA.

COLOURS OF BARE PARTS. Iris brown. Bill brown with orange tinge, brighter orange at gape and on basal half of lower mandible; mouth brownish, yellow, and pink. Legs and feet pinkish flesh colour; claws dusky.

MISCELLANEOUS. Parasitized by tick *Haemaphysalis spinigera* (Rajagopalan, JBNHS 69: 62). Vast numbers killed for food on southern Tamil Nadu coast during migration, especially autumn. On return migration (northward) from Ceylon the birds are attracted to the lights of residential buildings on foggy nights, as many as ten sometimes being taken in one particular Rest House (Ella) during a single evening (CBCN April 1982).

868. **Bluewinged Pitta.** *Pitta moluccensis megarhyncha* Schlegel

Pitta megarhyncha Schlegel, 1863, Vög. Ned. Ind., Pitta: 32 (Banka)
Baker, FBI No. 1322, Vol. 3: 452
Plate 63, fig. 11

LOCAL NAMES. None recorded.

SIZE. Quail; length c. 23 cm (9 in.).

FIELD CHARACTERS. A brightly coloured dumpy stub-tailed terrestrial bird. Very like the nominate race of S. Burma (illustrated), but larger and with a larger bill.

Adult. *Above*, whole crown fulvous-brown; lores, cheeks, ear-coverts, a stripe over eye, and a broad band round back of head black; a dark brown coronal stripe from forehead to nape. Upper back and mantle dull green; rump, upper tail-coverts and smaller upper wing-coverts ultramarine blue. A white patch on black primaries, particularly conspicuous in flight. *Below*,

PITTAS

255

Young (immature) like adult but with the crimson of abdomen and vent pale.

STATUS, DISTRIBUTION and HABITAT. Chiefly resident, but with some seasonal altitudinal and dispersal movements. The Himalayas from the adjacent plains through the terai, duars and foothills up to c. 2000 m—Uttar Pradesh, Nepal, Bihar, Sikkim, West Bengal, Bhutan and NEFA. Assam, Nagaland, Manipur, Mizo and East Pakistan (hill tracts). Affects subtropical moist-deciduous and evergreen secondary forest and scrub jungle.

Extralimital. Burma, Malaysia, and the Indochinese countries.

GENERAL HABITS, and FOOD. As in Indian Pitta (867), q.v.

VOICE and CALLS. Described by Baker as 'a loud musical whistle'.

BREEDING. *Season*, chiefly April-May-June. *Nest*, like that of 867, a loosely put-together oval ball of bamboo leaves, lined with grass and leaves. Normally placed on the ground in thick cover, e.g. under bamboo clumps etc. in dense secondary jungle. *Eggs*, 4 or 5, indistinguishable from those of Indian Pitta (867), q.v. Average size of 50 eggs 27.1 × 21.0 mm (Baker). Both sexes share in building the nest, incubation, and presumably also tending the young. Incubation period undetermined.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

Nestling. Brown of crown rather duller; black of chin, sides of head and narrow collar also duller; upperparts brown washed with green; upper tail-coverts dull pale greenish blue; tail dark brown washed with green; lesser wing-coverts dull green with narrow brown rims; median coverts white, with greenish brown concealed bases and very narrow brown margins; greater coverts dull green; quills as in adult but duller; throat brownish white; rest of underparts dull brown, paling to pink on abdomen, vent and under tail-coverts (Baker).

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂ ♀	109-119	(from feathers) 20-22	38-42	39-42 mm (Baker)
		(from skull)		
9 ♂♂	108-118	25-27	—	37-41 mm
4 ♀♀	110-118	25-26	40 (1)	37-40 mm (BB, SA)

Weight ♂♂ 2.2-5 oz. (= c. 57-71 g) — Davison.

COLOURS OF BARE PARTS. Iris dark brown; eyelids plumbeous. Bill black; mouth brownish fleshy. Legs and feet dark slate; claws yellowish grey.

870. *Pitta sordida abbotti* Richmond

Pitta abbotti Richmond, 1902, Proc. U.S. Nat. Mus. 25: 298 (Nicobars)
Baker, FBI No. 1326, Vol. 3: 457

LOCAL NAMES. None recorded.

SIZE. Quail; length c. 19 cm (7½ in.).

FIELD CHARACTERS. As of 869. See Museum Diagnosis.

254

PASSERIFORMES

ruddy buff with a broad bright crimson stripe down abdomen, vent, and under tail-coverts. Sexes alike.

Young (immature) has the feathers of head margined with black; back dull brownish green; underparts duller and browner, with little or no indication of the crimson abdominal stripe.

STATUS, DISTRIBUTION and HABITAT. An eminently migratory pitta, chiefly extralimital. Only a single record within our area: a specimen collected in March 1925 in East Pakistan — Barisal, 22°41'N., 90°20'E. (Whistler, JBNHS 37: 222), doubtless on migration.

Extralimital. Southern Burma (Tenasserim), Malay Peninsula, Sumatra.

GENERAL HABITS. More or less as in Indian Pitta (867). Frequents thin tree jungle with sparse undergrowth, mangrove swamps, gardens and plantations, etc.

FOOD. Ants and their larvae, other insects, grubs and land shells.

VOICE and CALLS. A fine clear double note, constantly uttered in the morning and evening from high tree-tops; often all day and also during moonlit nights (Davison, SF 6: 241).

BREEDING. Extralimital. Breeding biology as of the pittas in general.

MUSEUM DIAGNOSIS. See Key to the Species and Field Characters.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂ ♀	114-120	(from feathers) 29-34	39-41	40-43 mm (Baker)

Weight 4 oz. (= c. 113 g) — Davison.

COLOURS OF BARE PARTS. Iris dark brown. Bill black. Legs and feet dark fleshy; claws more whitish.

PITTA SORDIDA (F. L. S. Müller): HOODED OR GREENBREASTED PITTA

Key to the Subspecies

Brighter and paler above and below.....*P. s. cucullata*
Darker both above and below.....*P. s. abbotti*

869. *Pitta sordida cucullata* Hartlaub

Pitta cucullata Hartlaub, 1843, Rev. Zool.: 65 (Malacca)
Baker, FBI No. 1325, Vol. 3: 455
Plate 63, fig. 9

LOCAL NAME. *Phattim pho* (Lepcha).

SIZE. Quail; length c. 19 cm (7½ in.).

FIELD CHARACTERS. A multicoloured, largely green, dumpy, stub-tailed terrestrial bird. *Above*, crown and nape rich rufous-brown; lores, cheeks, ear-coverts, chin, throat and collar surrounding the head black. Mantle, back, and rump dark glossy bluish green; upper tail-coverts and a patch on wing-shoulder (lesser coverts) bright ultramarine blue; primaries black with a prominent white patch; tail black tipped with blue. *Below*, breast and sides of body pale greenish blue; abdomen black; lower abdomen, vent and under tail-coverts bright crimson. Sexes alike.

256

PASSERIFORMES

STATUS, DISTRIBUTION and HABITAT. Endemic in the Great and Little Nicobar islands. Keeps to the ground in heavy forest.

GENERAL HABITS, FOOD, VOICE and CALLS. Nothing specifically recorded as different from 869 and other pittas, though reported to perch less in trees and keep more to the ground than Indian Pitta.

BREEDING. Not recorded.

MUSEUM DIAGNOSIS. Differs from *P. s. cucullata* (869) in being darker above and below, lighter blue on upper tail- and wing-coverts and having a dark median line on crown. White patch on primaries much smaller and confined to six feathers instead of seven.

MEASUREMENTS

	Wing	Bill	Tarsus	Tail
♂ ♀	103-110	(from feathers) 22	40	39 mm
		(from gape) 27		(Richmond)

COLOURS OF BARE PARTS. Iris dark brown. Bill black; gape pale orange. Legs and feet pale brownish fleshy (Richmond).

871. *Blue Pitta.* *Pitta cyanea cyanea* Blyth

Pitta cyanea Blyth, 1843, Jour. Asiat. Soc. Bengal 12: 1008 (Arrakan)
Baker, FBI No. 1320, Vol. 3: 448
Plate 63, fig. 8

LOCAL NAME. *Daobui getanglili* (Cachari).

SIZE. Quail +; length c. 23 cm (9 in.).

FIELD CHARACTERS. A brightly coloured pitta largely blue overall.

Male. *Above*, forehead and crown greenish grey changing to scarlet on short nuchal crest; a broad black streak from bill through eye to nape; a black median streak on crown; black moustachial-streaks on either side of whitish throat; upperparts and tail blue. A white patch at base of black flight-quills, concealed at rest prominent in flight. *Below*, pale blue (yellowish on breast) spotted and brokenly barred with black.

Female differs from male chiefly in having the upperparts dull brownish suffused with pale blue, changing gradually to pure blue on rump, upper tail-coverts, and tail.

Young (immature) like female but retains the fulvous tips to wing-coverts and often shows faint signs of barring above.

STATUS, DISTRIBUTION and HABITAT. Resident, and seasonal local migrant; extent and details of movements not yet worked out. Nowhere common: the lower eastern Himalayas in Bhutan and NEFA. Also Assam, Nagaland, Manipur, Mizo, and East Pakistan (hill tracts); chiefly plains, duars and foothills, sparingly up to c. 2000 m. Affects dank ravines and scrubby undergrowth in mixed tree and bamboo forest in evergreen biotope.

Extralimital. Burma south to Tenasserim, and Thailand. The species extends to the Indochinese countries.

GENERAL HABITS. Largely as in Indian Pitta (867), q.v. Keeps singly on the ground in undergrowth, hopping about, turning over or flicking aside the dry leaves like a thrush, and digging into the damp soil with its bill for

PITTAS

257

food. When alarmed disappears into cover by long swift jumps like some small rodent, or flies up into a tree whence it soon descends again.

FOOD. Ants and other insects, grubs, land snails, etc.

VOICE AND CALLS. 'A clear, full double whistle' (Davison).

BREEDING. Season, principally May-June-July. Nest, as of Indian Pitta—an oval ball of loosely put-together bamboo leaves, roots and rubbish c. 30 × 25 cm with the entrance-hole at one end; placed on the ground or sometimes on top of a rock or dead tree-stump in a moist overgrown ravine or scrub and bamboo jungle. Eggs, normally 4 or 5, glossy white, broad ovals as characteristic of the pittas, speckled, spotted or blotched variably from pale reddish to deep purple-black. Average size of 50 eggs 27.6 × 20.9 mm. Breeding biology and incubation period not recorded.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

'Nestling' (= juvenile?). Above brown, the head almost black, each feather with a fulvous centre, bright and broad on crown and nape reduced to dull narrow lines on back; wing-coverts with terminal fulvous spots; rump and upper tail-coverts bluish; tail blue. Below, chin and throat white, each feather narrowly edged with black; breast and underparts dark brown, each feather broadly streaked with fulvous; centre of abdomen and under tail-coverts almost white (Baker).

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	106-116	22-24	43-45	57-62 mm (Baker)

Weight ♂ ♀ 3.5-4.25 oz. (= c. 99-120 g) — Davison.

COLOURS OF BARE PARTS. Adult. Iris dark reddish brown; eyelids plumbeous. Bill black; mouth dusky fleshy. Legs pinkish flesh colour. Juvenile ('nestlings and young birds' — Baker). Bill fleshy scarlet; culmen and base mottled with horny brown. Legs and feet paler than in adult.

(Near Meegui, Tenasserim)
Baker, FBI No. 1626, Vol. 4: 367

SIZE AND FIELD CHARACTERS. As of 670, q.v., but darker and greyer.

STATUS, DISTRIBUTION AND HABITAT. Presumably a winter visitor. Uncommon? A specimen taken at sea north of Andaman Is. (JBNHS 67: 331) and another near Port Blair (ibid. 69: 125). A third at Phuntsholing, Bhutan (ibid. 68: 451).

APPENDIX

259

p. 210

831a. *Black Woodpecker*. *Dryocopus martius khamensis* Buturlin

Picus khamensis Buturlin, 1909, Annuaire Mus. Zool. Acad. Sci.,
St Petersburg, 13 (1908): 229
(‘eastern slope of the great plateau of Tibet’)
Not in Baker, FBI

SIZE. House Crow +; length c. 46 cm (18 in.).

FIELD CHARACTERS. A large all-black woodpecker, similar to 831. Male with slightly crested crimson crown; female with restricted crimson patch on back of head. Eyes pale yellow.

STATUS, DISTRIBUTION AND HABITAT. Resident in the Tsangpo valley (SE. Tibet) between c. 93° and 95°E., in conifer forest between c. 2800 and 3800 m. Presumably also occurring in adjoining Arunachal Pradesh.

EXTRALIMITAL. The species (in several races) ranges over continental Europe eastward to Kamchatka and W. China.

GENERAL HABITS, etc. Those of the family.

MUSEUM DIAGNOSIS. ‘Similar to nominate *martius* but darker, purer black, and slightly more glossy in fresh plumage; bill proportionately shorter and averaging weaker. Wing length 15 ♂ & 246-260 (251.5) mm’ (Vaurie, *Bds. Pal. Fauna*, 2: 697).

• *Caprimulgus aegyptius* Lichtenstein, 1823, Verz. Doubl. Zool. Mus. Berlin: 59
(Upper Egypt)

SIZE. Myna; length c. 25 cm (10 in.).

FIELD CHARACTERS. Very similar to *Caprimulgus maharattensis* (674). Above, uniform pale sandy, lightly vermiculated on wings and head. Below, same colour faintly streaked with blackish; a white chin-spot. White spots on primaries confined to inner webs. Sexes nearly alike: two outer rectrices of male with buff tips; these obsolete in female.

STATUS AND DISTRIBUTION. Believed to breed in N. Baluchistan. A specimen collected at Robat on the Baluchistan-Iran-Afghanistan frontier on 12 April 1939 and another seen (A. E. P. Christison, JBNHS 43: 483).

EXTRALIMITAL. Breeds in Transcaspia, Turkestan, Afghanistan, E. and S. Iran, N. Egypt and Sudan (Peters).

MEASUREMENTS. Wing 197-218 mm (Meinertzhagen). Tail c. 130 mm (HA).

p. 82

727a. *Malay Threetoed Forest Kingfisher*. *Ceyx erithacus rufidorsus* Strickland

Ceyx rufidorsus Strickland, 1846 (1847), Proc. Zool. Soc. London, pt. 14, p. 99 (Malacca)

FIELD CHARACTERS. Overall as 727, but upperparts uniformly rufous washed with lilac. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Aberrant straggler? A single specimen from the Sikkim terai in BNHS collection (Abdulali, 1964, JBNHS 61: 439).¹

EXTRALIMITAL. This form ranges through most of the Philippines and Malaysian subregion and the Indo-Australian archipelago (R. W. Sims, 1959, *Jour. Linn. Soc. London*, Vol. 44).

MUSEUM DIAGNOSIS. ‘Above red washed with lilac, heaviest on head and rump; below deep yellow, strongest across the breast; chin and upper throat white washed with yellow; wing-coverts like the back; primaries and secondaries black; first primary and the secondaries edged with rufous; wing lining yellow. Iris dark brown; bill and feet red. Wing 58; tail 23; culmen from base 40; tarsus 8; middle toe with claw 16’ (Hachisuka).

¹ How the bird reached the Sikkim terai seems a mystery. However, the possibility should not be overlooked that this is a rare polytypic mutant, a phenotype of reddish *rufidorsus* type appearing in a wild population of typical *erithacus*.

¹ Ascendant (as.), i.e. counting inwards.

1

LARKS

3

(spike-like) aspect of tail v. more spread-out and blacker; from Small Skylark by greater amount of mimicry in its song.

STATUS, DISTRIBUTION AND HABITAT. Resident; not uncommon but extremely local. West Pakistan (Sind, NW. frontier dists., Punjab including the Salt Range), Kashmir, Himachal Pradesh, Uttar Pradesh, Madhya Pradesh, Bihar and West Bengal (East Pakistan?); southward throughout the Peninsula (not yet recorded in Kerala). Absent in Assam; also in Nepal, Sikkim, Bhutan and Ceylon. Affects dry bush-covered undulating plains and foothills country, locally up to c. 350 m — grassland, fallow cultivation, and sparsely scrubbed sandy semi-desert.

Extralimital. The species in other races occurs in Burma, Thailand, Vietnam, Borneo, Java and Bali.

GENERAL HABITS. Keeps singly or in pairs or small scattered parties, running about on the ground picking seeds and insects. In the breeding season the song-flight of the male is a remarkable performance. The bird rises about 30 m up in the air — a lower ceiling than the Skylark's — and hovers on stiffly quivering wings in the style of the Skylark drifting hither and thither on the breeze, and back and forth over an extensive area for considerable periods (once timed 40+ minutes). He then descends rather precipitately to the ground, alighting on a bush or clod, the performance being repeated after a while.

FOOD. Grass- and weed seeds, ants, weevils and other insects.

VOICE AND CALLS. Flight-song, remarkably spirited and sustained; very similar to the Small Skylark's in tone and quality and almost identical with that of Sykes's Crested Lark, incorporating imitations of the calls of practically every bird that shares its habitat. The following species recorded in the mimicry in Kutch: Common Babbler, Tailor Bird, Franklin's, Rufous-fronted and Jungle wren-warblers, Redwinged Bush Lark, Wood Shrike, Purple Sunbird and Rain Quail; elsewhere the chatter of an annoyed Laggar Falcon and the shrill call of Pied Crested Cuckoo have also been heard. The imitations follow one another in rapid succession without the slightest pause, and the song may commonly be heard also during the night, both dark and moonlit.

BREEDING. Season, March to September, chiefly from mid June. Nest, a saucer or shallow cup of grass, lined with finer grasses; sometimes more or less domed. Placed on the ground in a clump of grass on the side of a nullah or in thin scrub jungle, usually well concealed. Eggs, 2 to 4, variable; greyish, greenish-, or yellowish white, sparsely or densely speckled and blotched all over with various shades of brown. Average size of 40 eggs 20.1 x 15.4 mm (Baker). Nuptial display similar to that of *Mirafra assamica* (873), q.v. Share of the sexes in the domestic chores, and incubation period, undetermined.

MUSEUM DIAGNOSIS. Primaries and secondaries with nearly the entire outer web deep rufous or chestnut. Middle pair of rectrices brown, broadly margined with rufous; the next three pairs almost entirely brown; penultimate pair brown on the inner web, rufescent white on the outer; outermost pair rufescent white with a blackish band on inner margin of inner web. For further details of plumage see Baker loc. cit.

In summer (breeding) the pale edges to the feathers of the upperparts get completely abraded, making them look much darker and more rufous.

872. Singing Bush Lark. *Mirafra javanica cantillans* Blyth

Mirafra cantillans Blyth, 1844-5, Jour. Asiat. Soc. Bengal 13: 960 (Bengal)

Mirafra cantillans bangri Koelz, 1939, Proc. Biol. Soc. Washington 52: 76

(Hospet, Madras Presidency)

Baker, FBI No. 1229, Vol. 3: 334

Plate 64, fig. 1

LOCAL NAMES. *Agün*, *Agin* (Hindi); *Burutta pitta*, *Agin pitta* (Telugu).

SIZE: Sparrow; length c. 15 cm (6 in.).

FIELD CHARACTERS. A brown hen-sparrowlike bird of open country with much rufous or chestnut in the wings. This particularly noticeable in flight which is undulating and rather pipit-like, also showing the white outer tail-feathers. Underparts fulvous, with the breast streaked with triangular brown marks. Sexes alike.

Difficult to distinguish from other similar larks except by its habits and behaviour. When aloft in song-flight may easily be confused with both Small Skylark (907, 908) and Sykes's Crested Lark (902). Possibly distinguishable from the latter, virtually its 'double', by narrowed down

x c. 1

ALAUDIDAE

4

Young. Boldly barred above with black and pale fulvous; more profusely and boldly marked with black on breast.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	74-82	c. 10-11	20-21	47-52 mm (Baker)
		(from skull)		
3 ♂♂	75-81	13-14	—	49-55 mm
1 ♀	80	14	22	51 mm (SA)

COLOURS OF BARE PARTS. Iris hazel brown. Bill horny brown, paler on lower mandible and commissure; mouth bright lemon-yellow. Legs and feet pale brownish flesh colour.

MIRAFRA ASSAMICA Horsfield

Key to the Subspecies

- | | |
|--|-----------------------|
| Upperparts ashy brown with dark centres; no tinge of rufous on back..... | <i>M. a. assamica</i> |
| Upperparts not very dark but very rufous..... | <i>M. a. affinis</i> |

873. Bengal Bush Lark. *Mirafra assamica assamica* Horsfield

Mirafra assamica Horsfield, 1839, Proc. Zool. Soc. London: 162 (Assam)

Baker, FBI No. 1231, Vol. 3: 336

Plate 64, fig. 2

LOCAL NAMES. *Aggiā* or *Aggin* (Hindi); *Bhiriri* (Bengal).

SIZE. Sparrow; length c. 15 cm (6 in.).

FIELD CHARACTERS. Above, ashy brown streaked with blackish with some chestnut prominent in wings, especially in flight. Below, fulvous, coarsely streaked with triangular brown marks. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Resident; common. From Haryana (Jagadhri, Ambala dist., Jones, JBNHS 31: 1004) eastward through Uttar Pradesh, Nepal (lowlands), Jalpaiguri duars, Bihar and W. Bengal to Assam and Manipur; south to northern Orissa and northern Madhya Pradesh. East Pakistan. Affects open grassland and cultivation; not ascending the hills to any height.

Extralimital. Burma. Other races in Thailand and the Indochinese countries.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 874, q.v.

BREEDING. Season, overall March to August, principally May and June. Nest, a shallow cup of grass, lined with finer grasses — as typical of most larks. Occasionally domed by the grass growing around it, either arching over naturally or twisted and interlaced by the birds. Placed on the ground in a shallow depression or in an old hoof-print of cattle. Eggs, 3 or 4 similar to those of the Singing Bush Lark (872) — greyish-, greenish-, or yellowish white speckled and blotched with brown. Average size of 60 eggs 20.3 x 15.3 mm (Baker).

LARKS

5

Nuptial flight thus described: From a prominent raised perch the bird launches itself into the air, fluttering its wings very quickly and singing a sweet but not powerful song. When it has risen some 50 feet or so, it stretches both wings out very stiffly and makes a long sliding stoop towards the ground but, before reaching it, again flutters upward. The glide and rise are repeated two or more times before the bird actually drops to the ground or to its original perch, where it often sings for a few seconds after its arrival' (Baker).

MUSEUM DIAGNOSIS. See Key to the Species. Primary-coverts dark brown, externally rufous. Primaries and outer secondaries dark brown, most of them externally margined with chestnut and all of them with a large portion of the inner web chestnut. Tail blackish brown broadly margined with rufous, the penultimate and outer feathers with the greater part of the outer web pale rufous. For other details see Baker, loc. cit.

Differs from *M. a. effinis* (874) in being ashy brown above with no tinge of rufous, the feathers dark-centred.

Young. Above, feathers fringed with rufous-white and with subterminal black bars; below, pale fulvous, streaked with black on breast.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	82-84	c. 13-14	24-25	45-50 mm (Baker)

Weight 2 ♂♂ 26, 32 g (GD).

COLOURS OF RARE PARTS. Iris brown. Bill: upper mandible dark horny brown, nearly black at tip, yellowish near gape; lower mandible yellowish horn. Legs and feet pinkish- or yellowish brown, or dull flesh colour.

874. Madras Bush Lark. *Mirafra assonica affinis* Blyth

Mirafra affinis 'Jerdon' = Blyth, 1845, Jour. Asiat. Soc. Bengal 13: 959 (Southern part of the peninsula of India)

Baker, FBI No. 1233, Vol. 3: 339

Plate 64, fig. 3

LOCAL NAMES. *Chirchira* (Hindi); *Eli jitta* (Telugu); *Vānāmpādi kūrūti* (Tamil); *Leper* (Madhya Pradesh); *Gomritā* (Sinhala); *Cherampati* (Malayalam).

SIZE. Sparrow; length c. 15 cm (6 in.).

FIELD CHARACTERS. As in 873, but prevailing tone of coloration rufous-brown instead of ashy brown. The large rufous or chestnut patch in the wing conspicuous in flight, and diagnostic. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Resident and common. Southern Orissa, southern Madhya Pradesh and Andhra, south through Tamil Nadu, Mysore and Kerala. Ceylon in the low-country Dry and Wet zones. Affects cultivation, sparse stony scrub-and-bush jungle and fallow land in open plains and plateau country. Commonly found on laterite and moorland soil where its coloration is remarkably obliterative.

LARKS

7

875, 876. Sind Redwinged Bush Lark. *Mirafra erythroptera sindiensis* Ticehurst

Mirafra erythroptera sindiensis Ticehurst, 1920, Bull. Brit. Orn. Cl. 41: 56 (Karachi, Sind)

Baker, FBI No. 1236, Vol. 3: 342

LOCAL NAME. *Agriji āgūn* (Gujarati).

SIZE. Sparrow; length c. 14 cm (5½ in.).

FIELD CHARACTERS. As in 877, q.v., but paler and greyer. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident; common. West Pakistan from the Baluchistan frontier east through Sind and Punjab (including Jhelum and Rawalpindi dists. — Waite, JBNHS 59: 961). Western Rajasthan and northern Gujarat (including Kutch dist.). Affects stony sparsely scrubbed semi-desert — fallow fields, grazing land, with scattered *Euphorbia* clumps etc.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 877.

BREEDING. Season, April to September, chiefly June and July (in Kutch). Nest and eggs as in 877.

MUSEUM DIAGNOSIS. Differs from nominate *erythroptera* (877) in being paler and greyer, less ruddy overall. Rufous on wing-quills, flanks, axillaries and under wing-coverts much paler. Intermediates along the boundaries of the subspecies difficult to place.

MEASUREMENTS. Not different from the nominate form.

	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	73-84	13-15	21-23	46-56 mm (SA)

COLOURS OF RARE PARTS. As in 877.

877. Redwinged Bush Lark. *Mirafra erythroptera erythroptera* Blyth

Mirafra erythroptera Blyth, 1845, Jour. Asiat. Soc. Bengal 13: 958

(Northern portion of the peninsula of India = northern Deccan)

Baker, FBI No. 1235, Vol. 3: 341

Plate 64, fig. 4

LOCAL NAMES. *Agriji* (Hindi); *Jhijhira* (Saugor, M.P.); *Chinna eli jitta* (Telugu).

SIZE. Sparrow; length c. 14 cm (5½ in.).

FIELD CHARACTERS. Above, fulvous brown, streaked with blackish. Bright rufous or chestnut prominent in the wings, especially in flight. Below, chin and throat whitish; rest of underparts pale fulvous, the breast spotted with triangular blackish marks. Sexes alike.

Very similar to and easily confused with Madras Bush Lark (874). See Museum Diagnosis.

6

ALAUDIDAE

GENERAL HABITS. Keeps singly or in pairs or small loose parties, running about quietly on the ground or perched on bushes, rocks, fenceposts and the like, sometimes quite high up in a leafless tree. The most characteristic habit of this and the closely related Redwinged Bush Lark (877) is perhaps their spectacular song- or display-flight chiefly in the breeding season. From some elevated perch the male suddenly flutters vertically up in the air for 10 metres or so, uttering a feeble mousy though spirited *steeet-steeet* etc. (or *siriririririri* . . .). This is immediately followed by a squeaky *wisee* (or *yusee*)-*wisee-wisee-wisee* etc. getting slower and slower in tempo and fading off towards the end. With this the bird floats or parachutes down in spirals or zigzags or more or less vertically back to the same or a nearby perch, wings held motionless and stiffly upstretched in a wide V above the back, and legs dangling below. In a stiff breeze the bird may sometimes be wafted backward, in 'reverse gear' as it were, or rotated and blown about this way and that. The entire performance lasts about 20 seconds, and at the height of the breeding season is repeated again and again every few minutes throughout the day, and presumably even at night, judging from the song to be heard in the darkness.

FOOD. Grass- and weed seeds, weevils, tiny beetles and other insects.

VOICE and CALLS. Normal call, uttered from a perch, a quick-repeated mousy *chip-chip-chip* (something between the low *cheep* of the Small Minivet and *chik-chik* of Tickell's Flowerpecker). Song as above.

BREEDING. Season, in South India December to May, chiefly March onwards; in Ceylon March to August, chiefly May, occasionally September. Nest and eggs (c/3 or 4) indistinguishable from those of 873. Average size of 50 eggs 20.6 × 15.5 mm (Baker). When disturbed off nest with hardest eggs or small chicks, parent performs 'broken-wing' distraction display, fluttering and dragging on the ground piteously within a few feet of the observer.

MUSEUM DIAGNOSIS. See keys to the Species and Subspecies. Differs from nominate *assamica* (873) in being more rufous above (i.e. greyish brown) and brighter fulvous below.

No prenuptial moult. Postnuptial moult begins with the body plumage and tertiaries, then spreads to the wing-quills and finally to the tail, the tail beginning sometimes after the body and wing moult is nearly finished. This order is apparently also observed in the postjuvinal moult, which is complete (HW).

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	77-88	15-18	24-27	42-52 mm
♀♀	75-82	13-17	24-28	39-45 mm (SA, HW)

Weight 11 ♂♂ 20-30 (av. 26.2) g — SA, SDR.

Birds from Ceylon and Kerala tend to have a sensibly larger bill.

COLOURS OF RARE PARTS. As in 873.

MIRAFRA ERYTHROPTERA Blyth

Key to the Subspecies

Paler; more grey, less rufous above *M. e. sindiensis*
Darker; more tinged with rufous above *M. e. erythroptera*

ALAUDIDAE

8

STATUS, DISTRIBUTION and HABITAT. Uttar Pradesh, Bihar and West Bengal. Southern Gujarat (intergrading with *sindiensis* in Kutch and Saurashtra) and eastward through Madhya Pradesh to Orissa; south through Maharashtra, Andhra Pradesh, Tamil Nadu, and Mysore. Not recorded from Kerala. Affects same biotope as 874 — stony and gravelly sparse scrub-and-bush jungle and fallow land, in open plains and plateau country. On laterite and moorland soil its coloration particularly obliterative.

GENERAL HABITS, FOOD, VOICE and CALLS. Almost identical with Madras Bush Lark, including the parachuting display-flight, q.v.; the two species indistinguishable unless in the hand.

BREEDING. Season, overall March to October. Nest, very like that of Madras Bush Lark (874) — a shallow cup of grass lined with finer grasses, often domed over by the growing grass around it. Placed on the ground in a small depression or hoof-print of cattle at the base of a thorn bush or grass tuft, in open scrub or arid waste land. Eggs, 2-4, indistinguishable from those of other *Mirafra*s — greyish-, greenish-, or yellowish white, speckled and blotched all over with brown. Average size of 50 eggs 19.5 × 14.5 mm (Baker). Many published nesting records possibly vitiated through confusion in the field with Madras Bush Lark.

MUSEUM DIAGNOSIS. *M. erythroptera* differs from the species *M. assamica* mainly in the pattern of the chestnut on the wings. In the present species the chestnut on the outer and inner webs of the primaries is confluent instead of divided by a brown band or wedge. For distinguishing from *M. e. sindiensis* see Key to the Subspecies.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	75-84	13-15	21-24	47-55 mm (SA, HW)

Weight 13 ♂♂ 17-27 (av. 21.3) g (SA).

COLOURS OF RARE PARTS. Iris hazel brown. Bill horny brown on culmen, pale flesh on lower mandible and commissure; mouth pale pink. Legs and feet pale flesh colour; claws dusky.

Genus EREMOPTERIX Kaup

Eremopterix Kaup, 1836, Das Thierreich 2: 139. Type, by original designation.

Fringilla ocleuca Temminck = *Alauda melanocorypha* Lichtenstein

Pyrrhuloxia Swainson, 1873, Classif. Bds. 2: 125. New name for *Megalops* Swainson.

1827. Type, by original designation, *Fringilla ocleuca* Temminck

Bill very short and deep with culmen well rounded. Nostrils densely covered with plumbeous. Wing of 10 primaries: first primary (as.) very small, not exceeding the primary-coverts; 2nd, 3rd and 4th longest and subequal. Hindclaw short and well curved.

Key to the Species

Forehead and crown ashy brown *E. grisea*
Forehead white, crown blackish *E. nigripit*

LOCAL NAMES. *Diyora*, *Dūri*, *Dooli*, *Dūbāk chiri*, *Jothauli* (Hindi); *Māth charāi*, *Dhula chata* (Bengali); *Poti pichikā*, *Piyada pichikā* (Telugu); *Gotoarli* (Bihar mirshikars); *Gomerrittā* (Sinhala); *Vānāmpādī kūrūti*, *Mānām vānāmbādī* (Tamil); *Kūrimpāndi* (Malayalam); *Bhōn chikli* (Gujarati).

SIZE. Sparrow—; length c. 13 cm (5 in.).

x c. 1

FIELD CHARACTERS. A small, squat, thick-billed, crestless lark.

Male. Above, sandy brown with ashy crown, whitish cheeks, and a black streak from chin to eye. Below, brownish black.

Female. Sandy brown hen-sparrowlike.

STATUS, DISTRIBUTION AND HABITAT. Resident, common; subject to local seasonal withdrawals in the monsoon from heavy rainfall areas. West

Pakistan (Baluchistan, Sind, Bahawalpur, NW. frontier districts, Salt Range) and East Pakistan (Chittagong, Farcidpur, etc.). All India from the Himalayan foothills and terai (including Nepal terai) eastward to W. Bengal and Assam; south throughout the Gangetic Plain and the Peninsula to Kanyakumari; up to c. 1000 m. Also Ceylon in the low-country Dry and Wet zones. Affects stony sparsely scrubbed waste land; cultivation environs and village grazing grounds, paddy stubbles and ploughed fields, scraggy grass-covered sandy stretches by rivers and dry tidal mudflats near the coast, etc.

GENERAL HABITS. Keeps in pairs or small parties; in winter sometimes in largish scattered flocks. Is particularly fond of squatting and feeding on dusty cart-tracks, its coloration camouflaging the bird in a remarkable way. The birds shuffle along, body held low, in short jerky zigzag spurts in search of food. Parties roost at night on open sandy or gravelly ground, the birds squatting individually in tiny saucer-like depressions. Flight undulating—a series of rapid wing-beats (as in hovering) punctuated by momentary pauses. Male has a very spectacular song-flight and aerial display. From his perch on a stone on the ground he soars up vertically for 30 metres or so to hover in wide circles and sing in the typical skylark pattern. On completion of the song the performer nose-dives perpendicularly for a distance with wings pressed to the sides. At the bottom of the dive he suddenly pulls round to face the sky, and using the momentum aided by a few rapid wing-beats, zooms up a few metres once more. On the crest of the wave he reverses to repeat the nose-dive and descend a step lower, and so on (once 40+ dives counted over a stretch of c. 100 metres). Just when perilously near to crashing he opens his wings and flattens out to alight

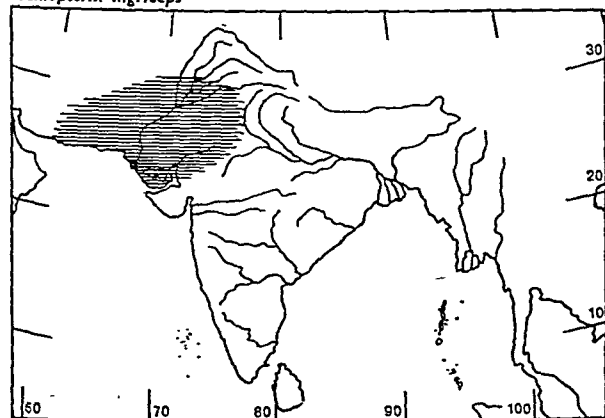

LARKS

11

Female like female 878, but paler and more sandy above; whiter below, more distinctly streaked with brown.

Young (immature) has sandier and paler upperparts than juvenile *grisea*.

STATUS, DISTRIBUTION AND HABITAT. Resident and also locally migratory. West Pakistan [Baluchistan on the Makran coast (Ormara, Pasni), Sind, Bahawalpur, Punjab Salt Range]. NW. India in Punjab, Haryana and Western Rajasthan (Jodhpur, Jaisalmer—very common). Has once been

Eremopterix nigriceps

Distributional range

E. n. affinis (879).

identified near Delhi (Najafgarh, February—Frome), and two specimens taken in northern Kutch (Kuar Bet, March 1960—SA). Status in the last two uncertain; possibly breeds in N. Gujarat, including Saurashtra and Kutch (Shivraj Kumar, JBNHS 66: 625). Affects sandy wastes and the neighbourhood of canal-fed desert cultivation.

EXTRALIMITAL. Persian Baluchistan, S. Iraq, Arabia, Somalia, Ethiopia, parts of western Egypt and Sudan (Vaurie).

GENERAL HABITS. Met with in scattered parties running about crouching to feed. Frequents a more arid sandy biotope than 878 where its pale coloration is even more remarkably adaptive and camouflaging. Courtship flight described as 'a short soar, not very high or of long duration, singing the whole time, followed by a sudden drop to earth' (Meinertzhagen, 1954). Strangely enough no mention is made of the spectacular aerobatics so characteristic of its Ashycrowned congener (878)! This needs verification.

FOOD. Grass- and weed seeds, and insects.

VOICE AND CALLS. Inadequately described.

BREEDING. Season, irregular, stretching chiefly between February and September. Nest and eggs (c/2) as in Ashycrowned Finch-Lark, usually

10

ALAUDIDAE

airily on a clod or stone. The whole performance may occupy 3 to 5 minutes, and the extravagant aerobatics are repeated at short intervals throughout the day.

FOOD. Grass- and weed seeds, ants, weevils and other insects.

VOICE AND CALLS. Song: a spirited trilling warble of the skylark pattern delivered in soaring-hovering flight, punctuated by a long-drawn clear whistle *wheteech* accompanying each nose-dive—a miniature 'screaming bomb'!

BREEDING. Season, irregular; continues more or less throughout the year, the principal months varying locally: chiefly February to September in the Peninsula, May and June in Ceylon. Nest, a deepish saucer-like depression in the ground (c. 5 cm diameter), maybe merely a hoof-print of cattle, neatly lined with fine grasses, hair or feathers, frequently rimmed around with a parapet of gravel. Placed in the shelter of a stone or small bush in open country—sometimes several nests a few metres from one another. Eggs, 2 or 3, pale yellowish- or greyish white, blotched and speckled with brown and lavender. Evidently female alone lines the nest, but male assists in incubation and tending the young. Incubation period undetermined.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

Young (immature). Like female, but with the feathers of upperparts broadly margined with pale rufous.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	74-80	11-13	15-17	40-46 mm
♀♀	72-79	11-13	15-17	37-44 mm
				(SA, HW)

Weight 11 ♂♀ 14-18 (av. 16) g—SA.

COLOURS OF BARE PARTS. Adult. Iris yellowish brown, reddish brown, or brown. Bill pale horny grey, dusker on culmen; mouth pale pinkish (with admixture of yellow in young birds). Legs, feet and claws brownish flesh colour.

NESTING. Iris brown. Bill greyish white, a black point each at tip of upper and lower mandible; gape and mouth bright orange; a black spot at tip of tongue and one on either side of its base.

879. Blackcrowned Finch-Lark. *Eremopterix nigriceps affinis* (Blyth)

Plate 64, fig. 6

LOCAL NAMES. *Duri*, *Dūbāk chiri* (Hindi).

SIZE. Sparrow—; length c. 13 cm (5 in.).

FIELD CHARACTERS. Male very like male Ashycrowned Finch-Lark (878) but much paler and sandier above, with white forehead and chocolate-black crown and nape. Ear-coverts pure white & dirty white.

ALAUDIDAE

12

placed at the foot of a grass-tuft in open sandy country, 'invariably on the northern side evidently to be sheltered from the hot wind' (Sind. Doig, SF 9: 281). Average size of 30 eggs 19.2 × 13.8 mm (Baker).

MUSEUM DIAGNOSIS. See Key to the Species and Field Characters.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♀	78-83	c. 12	16-17	46-51 mm
				(Baker, HW)

COLOURS OF BARE PARTS. Iris brown. Bill pale horny, darker on culmen, paler and bluish on lower mandible. Legs and feet pale whitish brown.

Genus *AMMOMANES* Cabanis

Ammomanes Cabanis, 1831, Mus. Hein. 1: 125. Type, by original designation, *Alauda arvensis* Sundevall

Bill thick, slightly curved: nostrils covered by plumelets. Wing of 10 primaries: 1st primary (as.) one-third the length of second; 3rd, 4th and 5th primaries subequal and longest. Hind claw about equal to hind toe and not much curved.

Key to the Species

Tail brown throughout tinged with rufous..... *A. deserti*
Tail deep rufous tipped with black..... *A. phoenicurus*

880. Indian Desert Finch-Lark. *Ammomanes deserti phoenicuroides* (Blyth)

M. (irafra) phoenicuroides Blyth, 1853, Jour. Asiat. Soc. Bengal 22: 583 (Kashmir)
Baker, FBI No. 1244, Vol. 3: 352

Plate 64, fig. 7

LOCAL NAMES. *Dāshti-chājok* (Baluchi); *Kompi* (Brahui).

SIZE. Sparrow; length c. 16 cm (6 in.).

FIELD CHARACTERS. Above, pale earthy brown tinged with pinkish rufous on upper tail-coverts, and with much rufous in the brown wings and tail; cheeks and ear-coverts greyish brown. Below, chin, throat and upper breast fulvous-white, faintly dark-streaked. Rest of lower plumage greyish rufous-pink. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Resident. Common in West Pakistan (Baluchistan, Sind, Bahawalpur, Punjab including the Salt Range); in NW. India in Kashmir and Jammu. Affects desolate barren country—stony hill-slopes and nullahs, and rocky ground along the base of the foothills, to c. 2000 m. Also fallow land in desert canal cultivation, e.g. Bahawalpur.

EXTRALIMITAL. Adjoining portions of eastern Afghanistan. Numerous other races in Iran, Iraq, Arabia and northern Africa.

GENERAL HABITS. Similar to Rufoustailed Finch-Lark (882), q.v. Keeps in pairs or small family parties of 3 or 4 in bare stony environments where its plumage gives it perfect camouflage. In winter loose flocks of 20 or so. Observed drinking at a desert rain-puddle regularly in the morning at about 9.00 hrs., not in flocks like sandgrouse but in relays of 2 or 3 birds

at a time (SA — Bahawalpur). Whether also drinks at other times of day not known. In waterless tracts, the requisite moisture probably imbibed from dew.

FOOD. Seeds of various desert plants and grasses such as *Setaria verticillata* and *Panicum ramosum*. Also insects.

VOICE AND CALLS. Call-note 'a curious plaintive, dreamily uttered peef-peef-peef'. Song, delivered during a hesitating mounting flight with deeply flapping wings, a broken collection of disconnected notes syllabified as peef-peef-peef-peef-peef (Whistler); somewhat reminiscent of that of *Anthus similis* (C. H. T. Whitehead).

BREEDING. Season, April to July, chiefly May and June. Nest and eggs (c/3 or 4) as in 882. Average size of 16 eggs 22.1 × 16.4 mm (Baker). Fledging period about 20 days (Whistler). No other details of breeding biology.

MUSEUM DIAGNOSIS. See Key to the Species and Field Characters. Nestling. Covered with thick long white down.

Young (immature). Paler above, the feathers with indistinct subterminal dark bars and pale tips. First primary (as.) longer, broader and blunter than in adult. Primary- and greater coverts, wing- and tail-quills with broader pale edges than in adult, and more rufous in colour.

MEASUREMENTS				
	Wing	Bill (from skull)	Tarsus	Tail
♂♂	98-107	15-16	22-23	65-70 mm
♀♀	96-101	15-16	22-23	62-66 mm
			(SA, HW)	

Weight 13 ♂♂ 22-29 g (Paludan).
COLOURS OF BARE PARTS. Iris hazel brown. Bill upper mandible dark horny brown; lower pale horny yellow. Legs and feet pale yellowish brown.

881. **Persian Rufostailed Finch-Lark.** *Ammomanes phoenicurus zarudnyi* Hartert

Ammomanes cinctura zarudnyi Hartert, 1902, Bull. Brit. Orn. Cl. 12: 43
(Mudjinabad, E. Iran)

Baker, FBI No. 1243, Vol. 3: 351
Plate 64, fig. 10

LOCAL NAMES. None recorded.
SIZE. Sparrow; length c. 16 cm (6 in.).
FIELD CHARACTERS. A thick-billed rufous-brown uncrested lark-like 882, q.v. See keys to the Species and Subspecies.

SIZE. Sparrow; length c. 16 cm (6 in.).
FIELD CHARACTERS. A rather squat, rufous-brown, stout-billed uncrested lark, with bright rufous tail ending in a black band, particularly conspicuous in flight. Sexes alike. Coloration very obliterative on laterite soil.

STATUS, DISTRIBUTION AND HABITAT. Resident; locally common; subject to some seasonal local movements especially in the monsoon. West Pakistan (Jhelum and Shahpur dists., Waite, JBNHS 59: 961). Mainly south and east of a line roughly from northern Kutch through Ajmer to Delhi; east to W. Bengal (south of Ganges R.) and south to a line from Hubli through Bellary — roughly the 15th parallel: thus in Gujarat (including Kutch and Saurashtra), Rajasthan, Delhi, Haryana, Uttar Pradesh, Bihar, Orissa, West Bengal, Maharashtra, Madhya Pradesh and northern Andhra. Affects open stony scrub-and-bush plains and plateau country, ploughed fields, fallow land, and the neighbourhood of cultivation, perching freely on telegraph wires rather than on bushes.

GENERAL HABITS. Keeps in pairs (very often trios) or small loose parties — sometimes in larger flocks of up to 50 or more. Runs about squatly in short zigzagging spurts in search of food. When disturbed flies off with a curious uncertain twisting flight and soon settles again. Frequently stampedes lurking insect prey from the unevennesses in the ground by a sudden flicking open and shut of the wings. Has a very impressive aerial display, the bird rising 30 m or so up in the air, flying around with deeply flapping wings and singing for several minutes, then rocketing down to earth with wings pulled in at the sides in a series of steps — steep nose-dives and 'wave-crests'. Pattern of the aerobatics very similar to that of Ashycrowned Finch-Lark (878), q.v.

FOOD. Grass- and weed seeds, grains of paddy and other cereals, and insects.

VOICE AND CALLS. A pleasant flight-song of several syllables comprising sweet thrush-like notes, tee-hoo, and low-pitched husky whistles and chirrups. Frequently parts of this song also uttered from a clod or stone on the ground.

BREEDING. Season, overall February to May, principally March and April. Nest, a cup-like hollow in a bank, or depression in the ground — often in a newly ploughed field — under shelter of a clod of earth or tiny bush. Usually padded with fine soft grass and often parapeded round the rim with pebbles, bits of sticks and other rubbish. Eggs, 2 to 4, creamy or greyish white in ground colour, freckled and spotted with reddish brown, umber-brown or inky purple, more densely at the broad end, forming a cap. Average size of 50 eggs 21.2 × 15.7 mm (Baker). Both sexes take part in lining the nest, incubation (?), and tending the young. Incubation period undetermined.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

MEASUREMENTS				
	Wing	Bill (from skull)	Tarsus	Tail
♂♂	100-110	15-17	21-24	57-64 mm
♀♀	98-104	15-16	21-23	52-63 mm
			(SA, HW)	

Weight 4 ♂♂ 24-28.5; 1 ♀ 23; 1 ♂ 27 g (BB).

STATUS, DISTRIBUTION AND HABITAT. West Pakistan; status uncertain. A specimen obtained by Blanford south of Sehwan in Sind, December 1873 (now in British Museum). Common and resident in western Chagai, Baluchistan, as far east as Ras Koh foothills (Christison, *Ibis* 1941: 544). Commoner in Zhob and Loralai than in other districts and probably occurs all over Baluchistan in suitable localities. Biotope as in 882, more rocky and barren wastes.

Ammomanes phoenicurus

Distributional ranges
phoenicurus (882). testaceus (883). zarudnyi (881).

EXTRALIMITAL. Eastern Iran from Kirman and southern Khorasan through southern Afghanistan (Vauric).

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 882, but recorded as perching on bushes and telegraph wires to sing, not soaring (Christison MS.)! This anomaly needs verifying.
BREEDING. As in 882, but not recorded within our limits.

MUSEUM DIAGNOSIS. Differs from nominate *phoenicurus* in being somewhat smaller and much paler with the underparts creamy rufous instead of deep rufous.
MEASUREMENTS. Wing ♂♂ c. 97-102 mm (Hartert); 2 ♂ 92, 93 mm (Baker).
COLOURS OF BARE PARTS. As in 882.

882. **Indian Rufostailed Finch-Lark.** *Ammomanes phoenicurus phoenicurus* (Franklin)

Mirastra phoenicea Franklin, 1831, Proc. Zool. Soc. London: 119
(Between Calcutta and Benares)
Baker, FBI No. 1242 (part), Vol. 3: 350

LOCAL NAMES. Aggiā, Rāḥl (Hindi); Lāl tharāt (Bengali); Khāḍrīyō (Gujarati); Āmbḍī jorī gādu, Dova pitta (Telugu); Vāṇḍāḍḍī kūrūvi (Tamil).

COLOURS OF BARE PARTS. Iris hazel brown. Bill horny brown, darker on upper mandible and tips; mouth dull orange, orange-pink, or flesh colour (age ?). Legs and feet brown; claws darker.

883. **Southern Rufostailed Finch-Lark.** *Ammomanes phoenicurus testaceus* Koelz

Ammomanes phoenicurus testaceus Koelz, 1951, Amer. Mus. Novit., No. 1510: 3
(Salem, Madras)
Baker, FBI No. 1242 (part), Vol. 3: 350

LOCAL NAMES. Āmbḍī jorī gādu, Dova pitta (Telugu); Vāṇḍāḍḍī kūrūvi (Tamil).
SIZE. Sparrow; length c. 16 cm (6 in.).

FIELD CHARACTERS. As in 882, q.v. See Museum Diagnosis.
STATUS, DISTRIBUTION AND HABITAT. Resident, subject to some seasonal local shifts. Peninsular India south of c. 15°N. lat., including Mysore, southern Andhra and Tamil Nadu. Oddly enough not yet recorded from Kerala, though doubtless occurring there in the appropriate biotope. Absent in Ceylon. Affects open stony scrub-and-bush country, fallow land, and the neighbourhood of cultivation.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 882.
BREEDING. Season, nest, eggs and breeding biology as in the nominate subspecies (882).

MUSEUM DIAGNOSIS. More rich rufous, less grey, above and below than nominate *phoenicurus*.
MEASUREMENTS AND COLOURS OF BARE PARTS. As in 882.

Genus ALAEMON Keyserling & Blasius

Alaemon Keyserling & Blasius, 1840, Die Wirbelth. Europas: 36. Type, by monotypy, *Alauda desertorum* Stanley

Distinguished by large size and long slender bill, slightly curved in its terminal half. Nostrils fully exposed. Wing long, of 10 primaries: 1st primary (as.) just exceeding the primary-coverts; 3rd, or 3rd and 4th primaries longest. Tarsi long and stout, scutellated behind; toes and claws short, the latter curved and blunt. 'Tongue bifid at tip' (Ticehurst).

884. **Large Desert Lark.** *Alaemon alaudipes doriae* (Salvadori)

Certhilauda doriae Salvadori, 1868, Atti R. Accad. Torino 3: 292 (Iran)
Baker, FBI No. 1205, Vol. 3: 304
Plate 64, fig. 8

LOCAL NAMES. Rāṇ chāṇḍū (Gujarati). Alternative English names 'Hoopoe-Lark' or 'Bifasciated Lark'.

LARKS

17

size. Myna —; length c. 23 cm (9 in.).

FIELD CHARACTERS. A large sandy grey lark with whitish underparts,

x c. 1

black-streaked on breast. Long slightly curved black bill and china-white legs. General effect on the ground between Crested Lark and Desert Courser. In flight, usually low above the ground, the broad white double band on the black wings and the black-and-white tail very striking, even at long range when the coloration of the bird otherwise masks it completely in the sandy environment. Sexes alike, but female smaller.

STATUS, DISTRIBUTION and HABITAT. Resident. Not uncommon, but local and very thinly scattered. West Pakistan in Baluchistan, Sind and Punjab (Bahawalpur and Multan dists.), and NW. India in and around

Alaemon alaudipes

■ Distributional range *A. a. doriae* (1884).

the Great and Little Rann of Kutch. Affects desert areas — undulating swells and mounds of drift sand with sparse bushes of *Salsola* and *Suaeda*, etc., or absolutely bare sunbaked salt-encrusted *pāts*.

Extralimital. Eastern Arabia, Iraq, southern Iran and Afghanistan. Other races in the Sahara and northern Africa.

LARKS

19

COLOURS OF BARE PARTS. Iris brown. Bill horny greenish grey: upper mandible pale plumbeous or pale brown, lower paler and more flesh coloured. Legs and feet china-white; claws greenish brown.

Genus *GALANDRELLA* Kaup

Calandrella Kaup, 1829, Skizz. Entw. Nat. Syst.: 39. Type, by monotypy,

Alauda brachydactyla Leister

Alauda Horsfield & Moore, 1858, Cat. Bds. Mus. E.I. Co. 2: 471. Type, by monotypy, *Alauda royal* Blyth

Bill rather short and deep. Nostrils concealed by plumelets. Wing of nine primaries: first primary (as.) long, reaching to tip of wing and more or less subequal with the next two or three. Inner secondaries long, reaching almost to tip of wing. Hindclaw a little longer than hindtoe and almost straight.

Key to the Species

	Page
A Inner secondaries falling short of wing-tip	
1 2nd primary about equal to 3rd and 4th (1st is minute)..... <i>C. royal</i>	26
2 2nd primary shorter than 3rd and 4th..... <i>C. rufescens</i>	25
B Inner secondaries reaching tip of wing

4 5th primary about equal to 2, 3 and 4..... <i>C. acutirostris</i>	22

GALANDRELLA CINEREA (Gmelin)¹

Key to the Subspecies

Upperparts strongly suffused with reddish; underparts fulvous.....*C. c. dukhunensis*
 Upperparts not strongly suffused with reddish; underparts whitish washed with fulvous-brown on breast.....*C. c. longipennis*

883. Yarkand Short-toed Lark. *Calandrella cinerea longipennis* (Eversmann)

Alauda longipennis Eversmann, 1848, Bull. Soc. Imp. Sci. Nat. Moscou 21: 219 (Sangara, Dzungaria)

Baker, FBI No. 1221, Vol. 3: 325

LOCAL NAMES. *Pillāk*, *Bāghārī* (Hindi); *Akoniā* (Bihar *mirshikars*).

SIZE. Sparrow; length c. 15 cm (6 in.).

FIELD CHARACTERS. A sparrow-like bird seen in large flocks in winter in open semi-desert country. Above, sandy or greyish brown streaked with blackish; a pale supercilium. Tail blackish with the two outer pairs of feathers largely white. Below, dull white, the breast washed and finely striated with brown. Sexes alike.

Gregarious habit (large flocks) and white underparts contrasting with the black tail in flight, distinguish this species from most other larks of this size. *C. acutirostris* (887-8) looks very similar, but has a rufous wash on the rump.

¹ Both Meinertzhagen and Vaurie (loc. cit., p. 1) combine this species with *brachydactyla*.

18

ALAUDIDAE

GENERAL HABITS. Usually met with singly or in widely separated pairs, often enormous distances out in flat featureless desert. Actions and behaviour very reminiscent of Desert Courser (439). Runs about hither and thither with mincing steps, stopping abruptly from time to time to pull itself erect or to pick up some morsel from the ground. Trusts to its legs for escape, taking wing reluctantly and only when pressed. Is a very swift runner, and if shot and merely winged it takes all-out sprinting to retrieve the bird! Flight wandering, similar to that of the Crested Lark; also reminiscent of the Hoopoe's, the resemblance being heightened by the black-and-white wing and tail pattern.

FOOD. Tiny beetles (Coleoptera) and other insects mostly picked off grasses; also seeds of *Suaeda* and suchlike desert plants.

VOICE and CALLS. Display. From the top of a bush or sand-mound the male springs up on fluttering wings more or less vertically for maybe 3 or 4 metres and nose-dives back to the perch, singing at the same time and displaying the striking black-and-white patterned wings and tail to best advantage. This manoeuvre is repeated again and again at short intervals. The song is a clear high-pitched mellow 3-noted whistle *tee-tee-tee* followed by a prolonged *tee-hoo* while nose-diving. 'The bird generally rises from the top of a sandhill after a preliminary tuning up of *too-too-tee-tee* whistled rather plaintively and deliberately and softly. The *too* is also an alarm cry' (T. R. Bell, MSS.).

BREEDING. Season, March to July, possibly straggling into September. Nest, a large untidy-looking structure of sticks etc. with a deepish cup in the centre (diam. c. 75, depth c. 40 mm) lined with fine twigs, grass stems, and feathers. Usually placed in a diminutive bush up to 60 cm or so from the ground, in desert country with a thin sprinkling of coarse grass clumps and bushes of *Suaeda* etc. Difficult to find but for the male displaying in its vicinity or the incubating female running away from the holding bush. Nest sometimes built in a straggly lone bush in a vast expanse of sunbaked *pāt*. Eggs, 2 or 3, longish oval, white to pale buff, blotched, spotted and speckled with reddish brown and faintly marked with lavender and grey — more densely at the broad end. Average size of 15 eggs 23.8 × 17.5 mm (T. R. Bell). Incubation by female alone (apparently); incubation period undetermined. Young, while still flightless, very fast runners. Mother bird gives distraction display, running in front of observer with dragging wings as if grievously injured.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit. When freshly killed the hindcrown is a delicate dove-grey. This colour disappears soon after death. In summer the plumage becomes very abraded and the spots on breast much more prominent.

Juvenile. Upperparts barred with blackish brown, each feather edged paler. No spots on breast. Wings and tail as in adult.

Nestling covered with very long pale buffy white down (Ticehurst).

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	126-137	30-35	34-37	79-99 mm
♀♀	116-119	c. 27	30-32	c. 75 mm (SA)

ALAUDIDAE

20

STATUS, DISTRIBUTION and HABITAT. Common and abundant winter visitor (September to April) throughout the northwestern desert and semi-desert portions: Baluchistan, Sind, Punjab (NW. frontier districts, Bahawalpur, Salt Range, etc.), Haryana, Delhi, western Uttar Pradesh, Rajasthan, northern Gujarat (including Kutch and Saurashtra), and northern Madhya Pradesh (Gwalior, Bhopal, Indore, etc.). Affects open stony scraggy grassland, flat barren *pāts* among sand-dunes and in semi-desert country, fallow cultivation in sandy riverain tracts, dry tidal mudflats in coastal areas, etc.

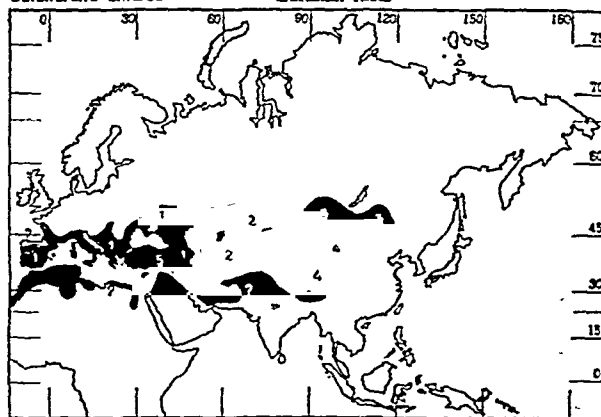

Extralimital. Breeds from southern Russian Altai eastward through northern Mongolia to Transbaikalia, northeastern Mongolia and northwestern Manchuria. Winters also in Afghanistan (Vaurie).

MIGRATION. No ringing data. Recorded on southward passage through Drosh and Chitral in large numbers, first week October; very common on return passage northward in April (Fulton, JBNHS 16: 56; Perreau, ibid. 19: 916). Passes southward through Kohat and Kurram Valley in September; common on return passage between last week February and mid April (Whitehead, JBNHS 20: 798). The observational data may also include 886.

GENERAL HABITS. Keeps in straggly flocks running about and feeding on the ground or moving restlessly around the countryside in undulating

Calandrella cinerea

Eurasian races

■ Breeding

For winter ranges see text

- 1 *brachydactyla* } (885). 4 *dukhunensis* (886).
 2 *longipennis* } (885). 5 *hermannensis* (RE).
 3 *orientalis* (RE).

pipit-like flight. The flocks are sometimes densely packed and of enormous size — 'clouds' of many hundreds, or thousands — e.g. upon their first arrival in winter quarters and again prior to emigration. The birds are

often seen feeding in the most barren-looking places with hardly a blade of grass growing, but where the ephemeral monsoon vegetation has evidently left an abundant supply of scattered seeds before dying down. The flocks fly out, sometimes considerable distances, to drink at favourite spots on river banks and the like every morning. They roost at night on bare open flats, each individual squatting separately in a round little depression in the soil.

Short-toed Larks become excessively fat before emigration and are then netted everywhere in vast quantities, being in great demand as an epicurean delicacy. They also constitute the staple diet of many of the resident as well as wintering birds of prey.

FOOD. Grass- and weed seeds: those of *Eleusine aristata* and *Eragrostis plumosa* (grasses), and *Trianthema pentandra* (a ficoid), identified among stomach contents (Ticehurst). Also eats insects.

VOICE and CALLS. Very silent in winter; only an occasional chirp.

BREEDING. Extralimital. Breeding biology as in 887-8.

MUSEUM DIAGNOSIS. 4th visible primary (as.) distinctly shorter than the first three. Upperparts greyer than in *dukhunensis* (886); underparts whiter.

MEASUREMENTS	Wing	Bill (from skull)	Tarsus	Tail (SA)
♂♂	95-100	12-15	20-21	54-65 mm
♀♀	88-94	12-14	20-21	53-57 mm

Weight 2 ♂♂ (winter) 19, 21.5; 3 ♀♀ (winter) 18-18.5 g (BB).
Wing 24 ♂♂ 91-98 (av. 93.8); 9 ♀♀ 85-90 (av. 87.7) mm } Paludan,
Weight 23 ♂♂ 19-25 (av. 22.3); 9 ♀♀ 19-22 (av. 19.9) g } Afghanistan
COLOURS OF BARE PARTS. Iris brown. Bill: upper mandible horny brown, darker on culmen; lower mandible yellowish horny. Legs and feet fleshy brown.

886. Rufous Short-toed Lark. *Calandrella cinerea dukhunensis* (Sykes)

Alauda dukhunensis Sykes, 1832, Proc. Zool. Soc. London: 93 (Dukhun)
Baker, FBI No. 1222, Vol. 3: 326
Plate 64, fig. 14

LOCAL NAMES. *Püllāk*, *Bāghēri* (Hindi); *Ākōnā* (Bihar mīshikars).

SIZE. Sparrow; length c. 15 cm (6 in.).

FIELD CHARACTERS. As in 885, but less grey more tawny; doubtfully distinguishable unless in the hand. See Museum Diagnosis.

× c. 1

STATUS, DISTRIBUTION and HABITAT. Probably breeds in Ladakh. Common and abundant winter visitor (September to April) from all along the base of the Himalayas, south through the Gangetic Plain and the Peninsula to Kerala. Less common in Assam and East Pakistan (?). By and large absent in West Pakistan and the adjoining arid semi-desert portions, but virtually replacing the Yarkand

887. Karakoram or Hume's Short-toed Lark. *Calandrella acutirostris acutirostris* Hume

Calandrella acutirostris Hume, 1872, Lahore to Yarkand: 265 (Balakchi, upper Karakash Valley, north of Sughet Pass, Karakoram)
Baker, FBI No. 1223, Vol. 3: 327

LOCAL NAME. *Bāghēri* (Hindi).

SIZE. Sparrow; length c. 15 cm (6 in.).

FIELD CHARACTERS. As in 885, q.v.; not distinguishable from it unless in the hand. Sexes alike. See keys to the Species and Subspecies.

On a good view, in flight, the rufous wash on rump sometimes helps to distinguish this species from *C. cinerea*, especially from the greyer subspecies *longipennis* (885) which otherwise looks identical with it.

STATUS, DISTRIBUTION and HABITAT. Breeds in Baluchistan, Gilgit, and the Sughet Range in Kunlun Shan to Zaskar and Rupshu (up to c. 5000 m), where it intergrades with *tibetana* (888). Chiefly winter visitor to West Pakistan and India south to northern Punjab, Uttar Pradesh and Madhya

Calandrella acutirostris

■ Breeding ▨ Winter *acutirostris* (887).
tibetana (888).

Pradesh. However, the two races are so close to each other that it is not always possible to assign even museum specimens with certainty. The situation is further complicated by the intermediates, and the extensive overlapping that occurs in their winter ranges. Sight records unsupported by specimens are quite worthless. Affects open, semi-desert country and fallow land, low stony foothills with scanty herbaceous vegetation, etc.

Extralimital. Breeds also in eastern Iran, north, central and eastern Afghanistan, and Badakhshan (Vaurie).

form (885) in central, eastern and southern India. Affects open stony, scraggy grass-covered country, cultivated tracts, ploughed fields, paddy stubbles, and dry tidal mudflats in coastal areas, etc.

Extralimital. 'Tibet, and Lop Nor to Ala Shan' (Vaurie).

GENERAL HABITS, VOICE and CALLS. As in 885, q.v. The various Short-toed Larks are notoriously difficult to identify in the field; assertions as to the occurrence, distribution, migration and breeding of this or that species or form, when unsupported by specimens, need to be treated with caution. However, their general habits, behaviour and food are almost identical, as is also the low chirping note occasionally heard in the winter quarters.

FOOD. Among stomach contents of birds from an intensively cultivated area in Bihar, in addition to grass- and weed seeds the following insects were commonly identified: weevils (*Tanymecus indica*, *T. hispidus*, and others), beetles (*Myllocerus discolor*, *Mesomorpha villiger*, and other species, and Aphodiids), ants (*Phidole malini*, *Oecophylla smaragdina*, *Camponotus compressus*, and ant pupae), small snails (*Corbicula* and *Planorbis* spp.), and geometrid caterpillars. Weevils constituted the major item (Mason & Lefroy, 1912).

BREEDING. Mainly extralimital. Only once recorded within our area, in the Suru Valley, Ladakh, between c. 3300 and 4000 m in July, by a reliable ornithologist. However, since apparently no specimen was collected, the subspecies remains in doubt and may as well be *longipennis*. Nests, several were found in a colony with those of the Horned Lark (*Eremophila a. longirostris*, 896) on a gentle mountain slope with scattered *Artemisia* and *Trollius* growth; described as a slight depression in the ground made by the bird in the shelter of a tiny plant, lined with a few blades of dry grass and a layer of fine, very soft vegetable down. Eggs, 3, in some cases 2, 'putty colour' mottled all over with yellowish brown. Average size 20.7 × 14.4 mm (B. B. Osmaston, JBNHS 31: 191).

MUSEUM DIAGNOSIS. Wing formula as in *longipennis* (885). Differs from it in being more rufescent brown above and on flanks; less white, more buff, on the underparts.

MEASUREMENTS	Wing	Bill (from skull)	Tarsus	Tail
♂♂	95-103	13-14	20-22	59-60 mm
♀♀	92-98	13-14	20-21	51-56 mm

(SA, HW, Koelz)

Weight 14 ♂♀ 18-23 (av. 20) g — SA.

COLOURS OF BARE PARTS. As in 885.

CALANDRELLA ACUTIROSTRIS Hume

Key to the Subspecies

White on tail less extensive and suffused with fulvous.....
..... *C. a. acutirostris*
White on tail more extensive and purer in colour. *C. a. tibetana*

GENERAL HABITS, FOOD, VOICE and CALLS. As in 888.

BREEDING. Season, May to July. Nest and eggs as in 888, but normal clutch in Baluchistan said to be of 4 (Williams, JBNHS 33: 607).

MUSEUM DIAGNOSIS. First four visible primaries (as.) nearly subequal, and longest. Differs from *tibetana* in having the white wedge on inner web of outer tail-feather less in extent, and white outer margin of 2nd tail-feather narrower.

MEASUREMENTS	Wing	Weight
11 ♂♂	89-96 mm	19-23 g
7 ♀♀	84-90 mm	18-21 g

(Paludan, Afghanistan)

COLOURS OF BARE PARTS. Iris brown. Bill yellowish horny, blackish on culmen and tip. Legs and feet fleshy brown; claws darker.

888. Tibet Short-toed Lark. *Calandrella acutirostris tibetana* Brooks

Calandrella tibetana Brooks, 1879, Stray Feathers 8: 488 (Tibet, beyond Sikkim)
Baker, FBI No. 1224, Vol. 3: 328

LOCAL NAME. *Bāghēri* (Hindi).

SIZE. Sparrow; length c. 15 cm (6 in.).

FIELD CHARACTERS. As in 887, q.v.; not distinguishable from it or from 885 unless in the hand. See keys to the Species and Subspecies.

STATUS, DISTRIBUTION and HABITAT. From Balistan, Zaskar, Rupshu, and Lahul (where it intergrades with 887), east through Ladakh, Nepal (recorded at c. 5000 m in May — Biswas, 1961, JBNHS 58: 443), N. Bhutan and SE. Tibet; breeding above c. 3400 m. Winter visitor to Punjab, Uttar Pradesh, Nepal, Sikkim, Madhya Pradesh, Bihar, West Bengal, Assam and East Pakistan. Affects open semi-desert country, fallow cultivation and waste land, low stony foothills with scanty herbaceous vegetation, etc.

GENERAL HABITS. Very like those of 885 and other Short-toed Larks, q.v. In its wintering range keeps in large straggly flocks running about and feeding on bare ground or flying about restlessly. Aerial display in breeding season, when in pairs, consists of a series of wandering wagtail-like flights after soaring aloft for 50 metres or so, each spurt ending in a short hovering and accompanied from time to time by a series of faint disjointed musical notes, mostly the normal sharp *tree*. This performance may continue for ten minutes or more, and ends with a vertical dive of the bird to the ground (Ludlow, SA).

Extralimital. Eastern Tibet and Sikkim to Koko Nor (Vaurie).

FOOD. Weed seeds and insects.

VOICE and CALLS. Normal note, a sharp *tree*. Song (as under General Habits) poor and monotonous; also uttered from the top of a rock or stone.

BREEDING. Season, in Ladakh end May to July. Nest, a slight depression in the ground scantily lined with dry grass and compactly felted within with very fine vegetable down or wool (usually white); diameter c. 60 mm, greatest depth c. 35 mm; sometimes parapetted round the rim with gravel. Placed in the shelter of a small plant or stone; frequently in quite exposed situations. Eggs, normally 3, sometimes 2, greyish white faintly stippled

LARKS

25

or splashed with pale brown, somewhat more densely at the broad end, there tending to form a ring. Average size of 25 eggs 20 × 14.5 mm (Ludlow). Both nest and eggs are smaller replicas of those of the Horned Larks (*Eremophila*) which share the same barren environments. Both sexes partake in collecting material and lining the nest; apparently also incubation. Incubation period undetermined. Parent performs 'broken wing' distraction display when nest with chicks approached.

MUSEUM DIAGNOSIS. Wing formula as in the species *acutirostris* (see Key, p. 19). Differs from the nominate race (887) in having the white wedge on inner web of outer tail-feather more extended, and white outer margin of second tail-feather wider.

MEASUREMENTS. Not different from 887.

Whistler (*Ibis*, 1932: 479) gives for a series of carefully sexed birds of the two forms together, as under:

	Wing	Bill (from skull)	Tarsus	Tail
33 ♂♂	98-100	13-15	19-22	54-58-65 mm
12 ♀♀	85-92	13-14	19-21	54-60 mm

COLOURS OF BARE PARTS. As in 887.

88Ca. Persian Short-toed Lark. *Calandrella rufescens persica* (Sharpe)

Alaudula persica Sharpe. 1890, Cat. Bds. Brit. Mus. 13: 590 (Niris, Iran)
Baker, FBI No. 1227, Vol. 3: 332
Plate 64, fig. 13

LOCAL NAME. *Bāghēri* (Hindi, for Short-toed Larks generally).

SIZE. Sparrow; length c. 15 cm (6 in.).

FIELD CHARACTERS. As of 885; distinguishable from it at close range by spotted breast, but usually not unless in the hand. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Winter visitor to West Pakistan — Baluchistan (this race and/or *seebahini*), Bahawalpur (JBNHS 42: 730) and elsewhere in Punjab (Peshawar and Hissar dists.), and possibly Sind. May be commoner than the records suggest, but overlooked amongst the other more abundant Short-toed Larks. Affects open sandy semi-desert country.

EXTRALIMITAL. 'Iranian Plateau, W. Iran (Zagros in Luristan), S. Iran. Scistan to SE. Afghanistan, S. Iraq' (Vaurie).

GENERAL HABITS, FOOD, VOICE and CALLS. Indistinguishable from 885 in winter.

BREEDING. Extralimital. More or less as in 885; described by Blanford. 1876, in *Eastern Persia* 2: 243 (under the name *C. pipioletta*).

MUSEUM DIAGNOSIS. In the species *C. rufescens* the secondaries are markedly shorter than wing-tip — always more than 15 mm. Breast more or less distinctly spotted; black spot on either side of throat (as in *acutirostris* and *cincera*) lacking. Subspecies *persica* is brown-streaked rufous sandy above; whitish below, spotted on breast. Outer tail-feather largely white.

A specimen of the very pale grey form *C. r. leucophaea* Severtzov has also been obtained in Baluchistan, in November, by Meinertzhagen (Ticehurst, JBNHS 11: 875).

LARKS

27

890. Saurashtra Sand Lark. *Calandrella raytal krishnakumarsinhji* Vaurie & Dharmakumarsinhji

Calandrella raytal krishnakumarsinhji Vaurie & Dharmakumarsinhji, 1954, Jour. Bombay nat. Hist. Soc. 52: 3 (Bhavnagar, Saurashtra)
Not in Baker

LOCAL NAME. *Ritāl* (Hindi).

SIZE. Sparrow —; length c. 13 cm (5 in.).

FIELD CHARACTERS. As in 891. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident. So far known only from the type-locality Bhavnagar in Saurashtra (Gujarat). Affects dry tidal mudflats along the coast (Gulf of Cambay) with scanty growth of rank grasses and saline plants (*Suaeda* etc.).

GENERAL HABITS, FOOD, VOICE and CALLS. As in 891. Common call-note a characteristic *cheruk-cheruk* (Dharmakumarsinhji).

BREEDING. Season, March to September, mainly from June on. Nest and eggs as in the nominate subspecies. Some nests sheltered under discarded dry coconut husks, a favourite site being the railway embankment across the mudflats.

MUSEUM DIAGNOSIS. Differs from both *adamsi* (889) and *raytal* (891) in being more heavily streaked and much darker in all plumages — dark grey above instead of sandy. Bill as in *adamsi*, shorter and thicker than in the nominate form. For details of plumage see Vaurie & Dharmakumarsinhji, loc. cit.

MEASUREMENTS

	Wing	Bill (from skull)	Tail
11 ♂♀	76-85	12-13	42-50 mm (Vaurie)

COLOURS OF BARE PARTS. As in 891, but 'bill blackish above and below'.

891. Ganges Sand Lark. *Calandrella raytal raytal* (Blyth)

Alauda raytal 'Buch.-Hamilton' = Blyth, 1845, Jour. Asiatic Soc. Bengal 13: 962 (Lucknow)
Calandrella raytal vauriei Koelz, 1954, Contrib. Inst. Regional Exploration, No. 1: 20 (Palasbari, Assam)
Baker, FBI No. 1225, Vol. 3: 329
Plate 64, fig. 15

LOCAL NAME. *Ritāl* (Hindi).

SIZE. Sparrow —; length c. 13 cm (5 in.).

FIELD CHARACTERS. Like Short-toed Lark (885) but smaller. Above, greyish sandy, narrowly streaked with dark brown. Below, white, sparsely and indistinctly dark-streaked on sides of breast. A white supercilium and cheeks. Shortish black-and-white tail. Sexes alike.

26

ALAUDIDAE

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♀	96-105	11-13	20-22	60-64 mm (SA, Baker)

COLOURS OF BARE PARTS. Iris grey-brown or brown. Bill horny grey, darker on culmen, yellowish on lower mandible. Legs and feet fleshy brown.

CALANDRELLA RAYTAL (Blyth)

Key to the Subspecies

		Page
A	More heavily streaked; much darker and greyer	
B	Less heavily streaked; paler and more sandy	
a	Bill slenderer and longer	C. r. raytal 27
b	Bill thicker and shorter	C. r. adamsi 26

889. Indus Sand Lark. *Calandrella raytal adamsi* (Hume)

Alauda adamsi Hume, 1871, Ibis 13: 405 (Agore Valley, Hazara)
Baker FBI No. 1226, Vol. 3: 331

LOCAL NAME. *Ritāl* (Hindi).

SIZE. Sparrow —; length c. 13 cm (5 in.).

FIELD CHARACTERS. As in 891, q.v. See Museum Diagnosis.

When in flocks in non-breeding season, may be distinguished from Short-toed Larks, with which they do not associate, by their greyer and whiter appearance, and silvery tinkling note (Ticehurst).

STATUS, DISTRIBUTION and HABITAT. Resident. Baluchistan (Makran coast), Sind, Punjab and Haryana east to the Jumna R., and Kutch. Affects bare sandy banks and islets in the larger northwestern rivers; salt-pan environs and dry open salty mudflats on the sea coast.

EXTRALIMITAL. Persian Baluchistan, west to c. 56° E. long. (Bandar Abbas).

GENERAL HABITS, FOOD, VOICE and CALLS. As in the nominate race (891).

BREEDING. Season, March to September, chiefly June to August. Nest, eggs, and breeding biology as in 891.

MUSEUM DIAGNOSIS. Differs from the nominate race (891) only in having a shorter and thicker bill with the culmen more curved. *C. r. krishnakumarsinhji* (890) has a similar bill but is distinctly darker, greyer, and more heavily streaked.

Juvenile undergoes a complete moult in autumn; in fresh plumage upperparts tinged with isabelline (Ticehurst).

MEASUREMENTS

28

ALAUDIDAE

STATUS, DISTRIBUTION and HABITAT. Resident. Northern India east of Jumna R. from Delhi and Haryana south and east through Uttar Pradesh, Nepal terai and plains, Bihar, northern W. Bengal, Bhutan foothills, the Brahmaputra Valley in Assam, and East Pakistan. Affects sandy river banks and islets in streams.

EXTRALIMITAL. Burma, along the lower Irrawady, Chindwin and other large rivers in the dry zone.

GENERAL HABITS. Keeps singly or in scattered twos and threes — frequently small flocks of 20 or 30 in non-breeding season — running about and feeding on bare sandy flats in the characteristic zigzag jerky spurts of the family. In breeding season male has an imposing song-flight. He soars aloft some 30 metres or so and flies aimlessly here and there while singing, not by a continuous hovering like the skylark but by intermittent series of rapid wing-flaps and pauses. The performance is short, lasting only a few minutes. The bird thereafter parachutes to the ground in a succession of 5 to 10 steps, wings and tail stiffly open, hovering momentarily at each step — reminiscent of the Tree Pipit's song-flight. In the final step of the descent, he shoots down vertically with closed wings, flattening out when within a metre or so of the ground to settle lightly on a clod or stone.

FOOD. Weed seeds and insects.

VOICE and CALLS. Song — usually uttered in flight, sometimes from a stone or mound — rather similar to that of Sykes's Crested Lark (902) but short and disjointed: a few tinkling notes . . . pause . . . a few more notes . . . pause, and so on. It is commonly interlarded with perfect imitations of the calls of many birds that share its habitat, e.g. the Redwattled Lapwing and Green Sandpiper. When singing from the ground, the crest is raised.

BREEDING. Season, February to May, chiefly March and April before the snow-fed northern rivers come in flood. Nest, a deepish cup-like depression in the ground at the base of a tamarisk seedling, or small arenicolous plant such as *Argemone*, or in the middle of a tuft of grass growing on a sandy river-bed or bank, sometimes in the shelter of a clod of river silt; lined with fine grasses, rootlets, goat's hair or vegetable down. Eggs, normally 3, sometimes 2, yellowish or greyish white with pale specks, freckles and small patches of greyish brown or pale reddish brown; they are small replicas of eggs of the Large Pied Wagtail. Average size of 20 eggs 20.1 × 14.6 mm (Baker). Evidently both sexes take part in all the domestic chores. Incubation period undetermined.

MUSEUM DIAGNOSIS. See Field Characters. Differs from *adamsi* (889) only in having a slenderer and slightly longer bill.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail

Wing under 130 mm; first primary brown on outer web, narrowly edged fulvous.....	<i>M. bimaculata</i>	29

892. Eastern Calandra Lark. *Melanocorypha bimaculata torquata* Blyth*Melanocorypha torquata* Blyth, 1847, Jour. Asiat. Soc. Bengal 16: 476 (Afghanistan) Baker, FBI No. 1210, Vol. 3: 312

Plate 64, fig. 11

LOCAL NAME. Jāl (Kashmir).

SIZE. Sparrow +; length c. 16 cm (6½ in.).

FIELD CHARACTERS. A large, rather dumpy lark with a very thick bill. General coloration rather like Rufous Short-toed Lark (886).

x c. 1

Above, dark brown, each feather edged sandy. A broad white supercilium and a dark line from lores to eye; cheeks and ear-coverts rufous-brown, streaked paler. Tail blackish brown edged paler, all rectrices except central pair white-tipped. Below, chin, throat, and sides of neck white. A large black spot on each side of upper breast tending to meet

across throat like a gorget; lower breast fulvous, streaked with brown. Rest of underparts white, washed with fulvous on flanks. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Fairly common winter visitor to Baluchistan (Quetta Valley, coastal Makran), Sind, Kashmir, Punjab, Haryana, Rajasthan and Uttar Pradesh (east to about Jumna river). A specimen collected in Kutch, February (Himmatsinhji, JBNHS 57: 408); another in December (SA). Chiefly passage migrant in Chitral and Gilgit, a few staying on in mild winters. Affects barren semi-desert, sparse cultivation, harvested and fallow fields, and margins of jheels; dry tidal mudflats in coastal areas.

EXTRALIMITAL. Transcaaspia, eastern Iran (Khorasan), N. and NE. Afghanistan; probably eastern Russian Turkestan and Kirghiz steppes (Vaurie).

MIGRATION. No ringing data. Passes through Gilgit in small numbers in October (Scully, SF 10: 134). Return passage starts about February.

LARKS

31

SIZE. Myna —; length c. 21 cm (8 in.).

FIELD CHARACTERS. As in the nominate form (894), q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Within our limits so far procured only in Ladakh (Rupshu) at c. 4350 m (Hanle) in July, so presumably breeding there. Affects grassy, humpy marshland in the vicinity of the high-elevation lakes in typical Tibetan plateau facies, between 4300 and 4600 m.

EXTRALIMITAL. Western, northern and eastern Tibet, Sikang (north of Kham), and Tsinhai to Kansu (Vaurie).

GENERAL HABITS. Largely as in 894. In breeding season SA found it singly or in scattered twos and threes keeping to the dry humpy margins of lakes and snow-fed bogs in the Manasarovar region of western Tibet. Males sing from the top of a grassy hump, twitching open the wings excitedly, drooping them at the sides of the partially cocked tail, and turning lightly from side to side. In chasing off a rival the bird flies at him low above the ground with leisurely-looking but deliberate and meaningful wing-beats. Before alighting to supplant, wings held up stiffly in a wide V above back and tail spread out, displaying the white pattern prominently. (For a fuller account of its ecology and biology see Schäfer, 1938: 187-90.)

FOOD. Seeds and insects.

VOICE and CALLS. Song rather feeble, of disconnected strophes interlarded with perfect mimicry of other birds' calls, e.g. Redshank (*Tringa totanus*) and Green Sandpiper (*T. ochropus*).

BREEDING. Unrecorded within our limits. In adjacent western Tibet (Lake Manasarovar area) SA found it breeding abundantly in June-July. Nest, a cup-like hollow in the ground lined with green grass; sited among the drier humps on the fringe of a seepage bog with spongy semi-floating grassy hummocks ('islets'). Eggs, 2 or 3, rather elongate, olive-creamy densely freckled with brown, almost masking the ground colour. Size c. 29 × 19 mm (SA).

MUSEUM DIAGNOSIS. See Key to the Species and Field Characters. Differs from the nominate form (894) only in being paler.

MEASUREMENTS and COLOURS OF BARE PARTS. As in 894.

894. Sikim Longbilled Calandra Lark. *Melanocorypha maxima maxima* Blyth*Melanocorypha maxima* Blyth, 1867 (January), Ibis: 46, footnote (Afghanistan, errors, restricted to borders of Sikim by Hartert, 1904)

Baker, FBI No. 1209 (part), Vol. 3: 311

Plate 64, fig. 16

LOCAL NAMES. None recorded.

SIZE. Myna —; length c. 21 cm (8 in.).

FIELD CHARACTERS. A dumpy thick-billed lark, similar to Eastern Calandra (892), but larger, with much more white in tail, and less prominent black spot on sides of breast.

Above, brown, tinged with rufous on head and rump, each feather dark-centred and pale-edged; supercilium and cheeks whitish; ear-coverts golden rufous. Tail brown, all rectrices except middle pair broadly white-tipped, the

30

ALAUDIDAE

Flocks of many thousands reach Kohat and Attock districts in February and early March (Whitehead, Ibis, 1909: 245), and Gilgit and Chitral by end February. By middle of March all the birds have moved on. Very plentiful in Chitral during end February and beginning March on northward migration (Fulton, JBNHS 16: 56), large flocks passing up the main valley in early March (Perreau, JBNHS 19: 916).

GENERAL HABITS. Met with in flocks while in its winter quarters, often of considerable size just prior to emigration ('hundreds'), usually in company with Short-toed Larks. The birds keep up a constant 'warbling' while squatted or running about on the ground.

FOOD. Seeds and insects.

VOICE and CALLS. 'Has a melodious call note' (Jones). Song not heard in winter.

BREEDING. Extralimital. Nest, a roughly put-together cup of grasses etc. on the ground; c/3 or 4.

MUSEUM DIAGNOSIS. See Key to the Species and Field Characters; for details of plumage, Baker loc. cit. Very similar to the nominate form *M. b. bimaculata* (of Transcaucasia, W. and S. Iran) but paler, greyer, and less heavily streaked.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	116-126	17-18	26-27	50-61 mm (Baker, SA)

Weight 3 ♂♂ 47-60 g (Paludan). 1 o ? (December) 48 g — SA.

COLOURS OF BARE PARTS. Iris light to dark brown. Bill: upper mandible brown to black; lower mandible greenish horny, yellowish at base. Legs and feet yellowish or brownish flesh colour, darker on the joints.

MISCELLANEOUS. Is excessively fat during the season of spring migration, when the birds are extensively netted, snared and shot in Kashmir and all along the migration route as an epicurean delicacy. Is also a very favourite cage-bird in those parts on account of its sweet rich song, similar to the skylark's — likewise interlarded with mimicry of other birds' calls — but richer and louder.

Soc. Washington 52: 127 (Hanle, Rupshu, Kashmir)

Baker, FBI No. 1209 (part), Vol. 3: 311

LOCAL NAMES. None recorded.

ALAUDIDAE

32

outermost feather nearly all white. Below, dull white washed with ashy on breast and with fulvous on flanks. A blackish spot on each side of breast; sometimes also a few ill-defined brown spots in the middle. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Resident. Northern Sikim and northern Bhutan in the Tibetan plateau facies; above c. 3600 m. Affects barren steppe country and humpy marshland around upland lakes and bogs.

EXTRALIMITAL. Adjoining southern Tibet (except in the far west where 893 replaces it) and southeastern Sikang (Kham) — Vaurie.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 893, q.v. 'When disturbed it utters a succession of loud musical whistles' (Ludlow).

BREEDING. Not recorded within our limits, but breeds plentifully in suitable situations in adjoining Tibet. Season, nest and eggs (c/2 or 3) as in 893. Average size of 5 eggs 29.3 × 18.5 mm (Ludlow).

MUSEUM DIAGNOSIS. See Field Characters and Key to the Species. The nominate form differs from that of Ladakh (893) only in being darker.

Young (immature). Above, blackish brown, each feather edged with yellow or yellowish white. Below, chin and throat distinctly yellow; rest of underparts washed with yellow, the breast heavily spotted with dark brown.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	143-154	21-24	29-30	83-93 mm (Baker)

COLOURS OF BARE PARTS. Iris dark brown, bill whitish horny or yellow, black at tip. Legs and feet dark brown or 'black mottled with dull red' (Walton).

Genus EREMOPHILA Brehm

Eremophila Brehm, 1828, Isis, col. 322. Type, by subsequent designation, *Alauda alpestris* Linnaeus*Olbcoris* Bonaparte, 1838, Nouv. Ann. Sci. Nat. Bologna 2: 407. Type, by subsequent designation, Gray, 1842, *A. alpestris* Linnaeus

Distinct from all other larks in the possession of 'horns' composed of a few lengthened feathers on either side of the crown in both sexes. Bill of medium length, rather stout. Nostrils densely covered by plumelets. Wing of only 9 primaries: first 3 (as.) subequal, the 2nd generally a fraction the longest. Tarsus strong, of moderate length; hindclaw straight, pointed, about same length as hindtoe or slightly longer. Sexes dimorphic in colour.

Cf. Whistler, H., 1925, Birds of Lahul. Ibis: 190-92 (Horned Lark).

Whistler, H., 1932, On some Larks of the Kashmir State. Ibis: 470-79.

Plate 64, fig. 18

LOCAL NAMES. None recorded.

SIZE. Bulbul; length c. 20 cm (8 in.).

FIELD CHARACTERS. A largish high-elevation lark, chiefly pinkish or vinaceous ashy brown above, white below. Face and throat whitish, with contrasty black cheeks running into a broad gorget across upper breast. A black band across crown and two tufts of long narrow feathers on either side (the 'horns') confirm its identity.

Female has the crown ashy brown without the distinctive black-and-white markings but more or less streaked with black. Black of face and breast duller

x c. 1

and more restricted.

STATUS, DISTRIBUTION and HABITAT. Resident in Gilgit and Chitral, moving altitudinally with season. Very common down at c. 1500 m between October and April whence, after forming large flocks ('of over a hundred') it suddenly disappears (Biddulph, *SF* 9: 354; Scully, *ibid.* 10: 134). Probably breeding in Chitral at the head of Turikho Valley c. 4000 m and upwards in July (Fulton, *JBNHS* 16: 56); spotted juveniles taken in August (Biddulph, *SF* 10: 274). A solitary straggler obtained in Rawalpindi dist., Punjab in March (Whistler, *JBNHS* 32: 218). Affects grassy pasture lands, banks of rivers, old moraines, and barren stony steppe country.

Extralimital. Iran in Yezd, and NE. Iran eastward from Gurgan through Khorasan, the mountains of Afghanistan, Transcaspiia, Pamirs, and western Tien Shan south to Kashgar and Yarkand in W. Sinkiang (Vaurie).

GENERAL HABITS, FOOD, VOICE and CALLS. As in 896 q.v.

BREEDING. As in 896.

MUSEUM DIAGNOSIS. Black areas of cheeks and upper breast confluent; forehead, face and throat in male always white, not yellowish.

Young (immature). Above, fulvous-brown, each feather tipped with white and subtipped blackish. Supercilium, sides of head, chin and throat yellowish; lores and ear-coverts mottled with brown. Below, breast brownish white with black spots; rest of underparts pure white.

LARKS

35

yellowish buff in ground colour densely freckled and mottled with some shade of dark brown. Average size of 11 eggs 24.5 × 17.4 mm (Osmaston). Female does (at least most of) the nest lining and incubation; male helps in feeding the young. Period of incubation undetermined.

MUSEUM DIAGNOSIS. See Key to the Subspecies; for details of plumage, Baker loc. cit. Frontal band in ♂ entirely white. Nasal plumes white at base, black at tip.

Chick (newly hatched) clothed in sparse straggly creamy white down. Supra-orbital, occipital, humeral, spinal, alar, and femoral tracts present. One terminal and two basal tongue-spots.

Young (immature), able to fly. ♂♀: Entire upperparts dark earthy brown each feather fringed or tipped with a pale yellowish buff spot, giving a spotted appearance. Lores and a patch behind eye yellowish white. Ear-coverts coalescing with a narrow moustachial streak earthy brown with pale yellowish buff fringes. Chin, throat, and a partial collar extending behind ear-coverts pale yellowish white. Breast yellowish buff, faintly spotted with blackish brown; abdomen, flanks and under tail-coverts white. Wings and coverts dark brown, all feathers broadly edged with yellowish or rufous-buff, this edge being white on basal half of second primary. Tail dark brown, the feathers edged and tipped with pale yellowish buff, most broadly on the outermost feather; central pair of tail-feathers mottled with rufous-brown. Mouth and gape yellow; no tongue-spots as in the chick. Bill, ♂ horny yellow, tip blackish; ♀ horny. Legs plumbeous-horn, soles yellowish (Whistler).

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	125-131	17-20	22-24	85-92 mm
♀♀	115-124	18-20	22-24	76-85 mm
(HW)				

COLOURS OF BARE PARTS. Iris brown. Bill black, base of lower mandible livid slate (in ♀ entire bill livid slate); mouth livid. Legs and feet black; soles horn colour.

897. Sikkim or Elwes's Horned Lark. *Eremophila alpestris eluesi* (Blanford)

Otocoris Eluesi Blanford, 1872, *Jour. Asiat. Soc. Bengal* 41 (2): 62
(Kongra Lama Pass, Sikkim)
Baker, *FBI No.* 1208, Vol. 3: 310
Plate 64, fig. 17

LOCAL NAMES. None recorded.

SIZE. Bulbul; length c. 20 cm (8 in.).

FIELD CHARACTERS. Both sexes as in 896, q.v. — also with a white band separating black cheeks from the broad pectoral gorget. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident, subject to some altitudinal movement in winter. From Rupshu and central Ladakh [where it intergrades with *longirostris* (896) in the region of Leh], eastward through Ladakh and the Himalayas, including Nepal, Sikkim, Bhutan and NEFA; from

46: 84 (Deosai Plateau, between Baltistan and Kashmir)

Baker, *FBI No.* 1207, Vol. 3: 309

LOCAL NAMES. None recorded.

SIZE. Bulbul; length c. 21 cm (8½ in.).

FIELD CHARACTERS. As in 895 but with a white band separating black cheeks from the broad pectoral gorget. See Museum Diagnosis.

Female like male but with no black band across forehead. Whole crown streaked dull black; 'horns' little more than black border to white supercilium; black of cheeks and gorget duller and more restricted.

STATUS, DISTRIBUTION and HABITAT. Resident, subject to some altitudinal movement in winter. Baluchistan and NW. Kashmir from the Karakoram

south to Baltistan, Zaskar, Lahul and Spiti, Kulu; intergrading with *eluesi* (897) in Rupshu (SE. Kashmir); from c. 3500 m up to snowline. Affects barren, stony steppe country, with scanty tufts of grass and herbaceous plants — *Artemisia* etc.; occasionally also alpine meadows.

GENERAL HABITS. One of the commonest and most abundant birds in its characteristic stony upland habitat where its coloration is remarkably oblitative. Keeps in pairs or trios; in non-breeding season in scattered flocks, sometimes of considerable size — 50 or more. Usually unafraid and confiding, running about in short spurts like a small plover or wagtail to feed, frequently in close proximity of caravans and encampments. Under excitement, as when facing up to a rival, the horns are raised. Flies with deliberate leisurely-looking full wing-beats, reminiscent of the Crested Lark (*Galerida cristata*, 899).

FOOD. Weed seeds and insects; occasionally barley gleaned in harvested upland fields.

VOICE and CALLS. A single rather mournful note *peo* occasionally uttered in flight, also reminiscent of Crested Lark's. In breeding season male sings from a rock a short, insignificant squeaky song of disjointed strophes of the volume and tone quality of a leaf-warbler's trill; 'somewhat resembles that of the Corn Bunting, and also song of the Indian Redstart' (Osmaston). Apparently has no song-flight.

BREEDING. Season, May to July. Nest, a cup-like depression in the ground about 7 cm across and 4 cm deep, neatly felted with dry grass, hair, wool or vegetable down usually white in colour. Placed in the shelter of a tiny plant or stone, usually on its leeward side as protection from the prevailing gales; sometimes quite in the open. Eggs, normally 3, sometimes 2, longish ovals, slightly glossy and often sharply pointed at the smaller end; pale

36

ALAUDIDAE

c. 3600 m up (obtained at c. 5500 m by Blanford). Descending to c. 3000 m in winter, occasionally lower (obtained at c. 1500 m in Sikkim by SA and BB). Affects bleak stony hillsides and barren windswept steppes, thinly dotted with scanty tufts of grass, *Artemisia* plants and *Caragana* bushes — the typical Tibetan Plateau facies.

Extralimital. Northern Sikkim on the steppes on the upper course of the Hwang ho, Yalung, and Yangtze, and westward through southern Tibet to Ladakh.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 896.

BREEDING. Season, nest, eggs (c/2 or 3) and breeding biology as in 896. Average size of 4 eggs 23.5 × 16.5 mm (Ludlow).

MUSEUM DIAGNOSIS. A small-billed race; paler, less streaked and more vinous above than *longirostris* (896). However, in fresh plumage upperparts darker and warmer than in *albigula* or *longirostris*; deeper pink on nape, this colour extending further down on the back and more so than in either of the above (Meinertzhagen).

MEASUREMENTS (of more or less topotypical Sikkim and Bhutan birds)

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	114-123	13-15	22-23	76-89 mm
♀♀	109-112	13-15	22-23	73-87 mm
(HW, SA, BB, RM)				

Weight 5 ♂♂ 32-37; 3 ♀♀ 29-34 g (GD).

COLOURS OF BARE PARTS. Iris brown. Bill: upper mandible horny black; lower plumbeous, brownish at tip. Legs, feet, soles and swollen pads under joints of toes greyish white; claws dark horny brown.

Genus GALERIDA Boie

Galerida Boie, 1828, *Isis*, col. 321. Type, by subsequent designation, *Alauda cristata* Linnaeus

Bill long and powerful. Nostrils covered by short plumelets. Head adorned with a thin but long upstanding crest. Wing of 10 primaries: first primary (as.) very small; 2nd reaches to nearly tip of wing; 3rd, 4th and 5th subequal and longest: in some individuals 2nd = 3rd. Hindclaw very straight, of about same length as hind toe.

898. Baluchistan Crested Lark. *Galerida cristata magna* Hume

Galerida magna Hume, 1871, Ibis: 407 (Yarkand)
Baker, FBI No. 1238, Vol. 3: 345

LOCAL NAMES. *Chindil* (Hindi for all Crested Larks); *Chigak*, *Chotib*, *Chigiz* (Baluchi); *Kerzlek* (Persian).

SIZE. Sparrow +; length c. 18 cm (7 in.).

FIELD CHARACTERS. As in 899, q.v. Indistinguishable from it unless in the hand. But when both races side by side in the field (winter) may be identified by its larger size and more sandy colour. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Breeds in Baluchistan [Kalat, Quetta and Fort Sandeman dists.; probably central Makran where intergrading with *chindola* (899) occurs]. Also breeds in the frontier mountains of West Pakistan (Kohat dist. and Chitral), above c. 2300 metres. Winters in Sind and NW. Punjab (Peshawar dist., where most numerous on spring and autumn passage. Briggs, JBNHS 32: 755). Affects desert tracts as well as cultivated semi-desert areas, often in the environs of towns and villages.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 899.

BREEDING. Season, March to mid May. Nest, eggs (cf 4 or 5) and breeding biology as in the Indian bird. Average size of 60 eggs 22.6 × 17.1 mm (Baker).

MUSEUM DIAGNOSIS. Paler and more sandy than *chindola* (899) and with a slightly thicker bill; but differs from it chiefly in being larger.

MEASUREMENTS

(London, Bombay)

Cf. Koelz, W., 1954, Contrib. Inst. Regional Exploration, No. 1: 33 (further comments on *profingus*)

Baker, FBI No. 1241, Vol. 3: 348
Plate 64, fig. 21

LOCAL NAMES. *Chinna chindil* (Telugu); *Kondai rani-baddi* (Tamil); *Komban rai-baddi* (Malayalam).

SIZE. Sparrow; length c. 15 cm (6 in.).

FIELD CHARACTERS. A rufous-brown lark with an upstanding pointed crest very similar to the larger and sandier Indian Crested Lark (899), q.v. Sexes alike. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident, apparently with some seasonal local movements, not worked out. Western peninsular India from c. 23°N. in Gujarat (Ahmedabad — 3 specimens, Hume coll. in B.M.), southward through western Maharashtra, western Mysore, western Tamil Nadu, and Kerala; plains and hills up to c. 2000 m. Affects open sparse scrub jungle, forest clearings, cultivation environs, grass-covered stony hill slopes with sheet-rock outcrops, etc. in dry- and moist-deciduous biotope; treeless downs in the S. Indian hills and grassy edges of tidal mudflats in coastal areas. Both this species and the next (902) usually found on dark soils matching the general tone of their plumage.

GENERAL HABITS. Very similar to those of Indian Crested Lark (899). In non-breeding season keeps in scattered parties of 5 to 8 birds or flocks of up to 30 or so. Wanders a great deal locally according to season, but pattern of movements not yet understood.

× c. 1

Above, sandy brown streaked with blackish. Below, white, fulvous and boldly streaked with dark brown on breast. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Resident; subject to some seasonal local movements. From Sind and the NW. frontier districts of West Pakistan, east through Kashmir foothills, Punjab (including Salt Range),

Haryana, Delhi, Uttar Pradesh, Nepal plains, Bihar and northern Madhya Pradesh; south in Rajasthan, northern Gujarat (including Saurashtra and Kutch). Affects open sandy or salt-encrusted semi-desert country, chiefly plains, and the neighbourhood of cultivation in such; grassy sandy riverain tracts; dry tidal mudflats in coastal areas.

GENERAL HABITS. Keeps in pairs or small scattered flocks. Pointed crest generally carried erect as the bird runs about picking food on the ground. Perches freely on bushes, fence-posts, and telegraph wires, etc. It is a favourite cage-bird for its song, and thrives well in captivity.

FOOD. Grains, weed seeds and insects — locust hoppers, ground beetles, ants, earthworms, etc.

VOICE and CALLS. Normal note a liquid, rather plaintive *tee-ee* or *tee-err*. Song, a clear pleasant warbling, also with occasional imitations of other birds interlarded, but of short, disjointed repeated strophes and comparatively colourless. Delivered during a modest song-flight, the bird fluttering up a few metres, flying about rather aimlessly over a circumscribed area with a leisurely fluttering or hovering action, then planing down to earth on stiffly outspread slightly quivering wings to alight on a stone or clod. The song is also uttered from a perch.

BREEDING. Season, overall March to August, chiefly April to June. Nest, a shallow cup of grass and roots in a hollow scraped in the ground, or old hoof-print of cattle, lined with finer grasses or hair. Concealed under a clod in a ploughed or fallow field, or at the foot of a grass-tuft or small plant (e.g. *Sida*) in sandy country; often banked up round the edge with flakes of unbaked earth or cowdung. Eggs, 3 or 4, dull yellowish- or greenish white, speckled and blotched with brown and purple, usually more densely at the broad end. Average size of 50 eggs 21.5 × 16.4 mm (Baker). Both sexes take part in building the nest, incubation, and feeding the young. Incubation period undetermined.

MUSEUM DIAGNOSIS. See keys to the Species and Subspecies. Differs from *magna* (898) in being darker and browner (less sandy) and having a slightly slenderer bill; but chiefly in being smaller.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	98-105	19-23	23-26	54-63 mm
♀♀	92-98	19-23	23-27	51-55 mm (SA)

Weight 10 ♂♀ 24-32 (av. 28) g — SA, BB.

FOOD. Weed seeds, often plucked off the living plant; paddy grains gleaned in stubbles, and insects — grasshoppers, ground beetles, ants, etc.

BREEDING. Season, varying with locality, practically all the year except perhaps the months of heaviest rainfall. Nest, a shallow cup of grass and rootlets lined with finer material, in a small depression in the ground, sheltered by a stone or grass-tuft. Eggs, 2 or 3, greyish white or creamy buff freely speckled all over with various shades of brown, with underlying specks and spots of lavender and grey. Average size of 40 eggs 21.5 × 15.5 mm (Baker). Breeding biology as in 899.

MUSEUM DIAGNOSIS. Smaller than 899 and with the upperparts rufous-brown instead of grey-brown. Differs from *G. deta* (902) in being larger, with the breast more heavily streaked with blackish.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	92-105	16-18	23-24	49-58 mm
♀♀	91-94	16-17	23-24	46-52 mm (SA)

COLOURS OF BARE PARTS. Iris hazel brown. Bill horny brown, paler on lower mandible; mouth chrome yellow (in nestling bright orange-red). Legs and feet fleshy brown; claws horny brown.

902. Deccan or Sykes's Crested Lark. *Galerida deta* (Sykes)

Alauda deta Sykes, 1832, Proc. Zool. Soc. London: 92 (Dukhun)
Mirafra cantillans bangsi Koelz, 1939, Proc. Biol. Soc. Washington 52: 76
(Hospet, Madras)
Baker, FBI No. 1240, Vol. 3: 347
Plate 64, fig. 19

LOCAL NAME. *Chinna chindil* (Telugu).

SIZE. Sparrow +; length c. 13 cm (5 in.).

FIELD CHARACTERS. A small rufous-brown lark with an upstanding pointed crest, similar to 899 and 901, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident; with some little understood seasonal local movements. Eastern Rajasthan, northern Gujarat and Kutch, east through the Gangetic Plain to c. 82°E. long. and south through the Peninsula, chiefly the central plateau, to southern Mysore (Rameswaram island?, Biddulph, JBNHS 40: 244); plains and hills to c. 1000 m. Affects stony, sparsely scrubbed ghat and plateau country, dry cultivation, etc. — usually dark coloured soils.

Range and habitats overlap those of 901 in many areas, but by and large this occupies the central plateau country farther inland from the coast. Some sight records almost certainly vitiated by confusing similarity, especially in song-flight, with *Mirafra j. cantillans* (872) and also Small Skylark (*Alauda fulgens*).

GENERAL HABITS. Similar to the Indian and Malabar Crested Lark (899 and 901), but song-flight and song entirely different: almost identical with those of Singing Bush Lark (872) and Small Skylark (907, 903) q.v. In one recorded case presence of Yellow-eyed Babbler in an apparently unlikely

LARKS

41

locality in Kutch initially suggested by this lark's vocal mimicry leading to subsequent confirmation (SA).

FOOD. Weed seeds and insects.

VOICE and CALLS. Song—delivered in soaring, hovering, wandering flight—almost identical with that of Singing Bush Lark (872) q.v. Of similar pattern and only slightly inferior, if at all, to the spirited melody of the Skylark, also embracing the same rapid succession of mimicked calls of other birds.

BREEDING. Season, overall March to September, chiefly May to August. Nest, site, and eggs (c/2 or 3, rarely 4) as in 901; the last smaller and somewhat more finely stippled with brown. Average size of 50 eggs 19.9 × 14.6 mm (Baker). Breeding biology as in 899.

MUSEUM DIAGNOSIS. Differs from Malabar Crested Lark (901) in being smaller, with the underparts darker and more rufous, without the whitish abdomen. Streaking on breast sparser and narrower.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	84-92	13-15	20-21	46-54 mm
♀♀	78-86	13-15	20-21	43-50 mm (SA)

Weight 5 ♂♂ 18-22 g (SA).

COLOURS OF BARE PARTS. Iris hazel brown. Bill pale flesh colour, horny brown on culmen; mouth pinkish yellow. Legs and feet brownish flesh.

Genus *ALAUDA* Linnaeus

Alda Linnaeus, 1758, Syst. Nat., ed. 10, 1: 165. Type, by original designation *Alda arvensis* Linnaeus

Bill slender and feeble, more so than in *Calandrella*. Nostrils covered by plumbelets. Wing of 10 primaries: first primary (as.) minute, of variable length in different subspecies; 2nd, 3rd and 4th primaries also variable in length, but wing always short, not reaching beyond middle of tail. Inner secondaries very long, but shorter than wing-tip. Tarsus long and fairly stout; hindclaw very long and nearly straight.

Not in Baker, FBI

Plate 64, fig. 23

LOCAL NAMES. None recorded.

SIZE. Sparrow +; length c. 18 cm (7 in.).

FIELD CHARACTERS. As of 903, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Winter visitor. Possibly more frequent than the only two specimens collected in W. Pakistan (Bahawalpur, February)¹ would suggest, but overlooked amongst *dulcivox*.

EXTRALIMITAL. Southern Europe from Spain eastward through the Balkan Peninsula, Greece and Bulgaria to Crimea, Caucasus, Transcaucasia, northern Iran, etc. For details see Vaurie, 1959, 2: 55.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 903.

BREEDING. Extralimital.

MUSEUM DIAGNOSIS. Slightly darker than *dulcivox*, less sandy in fresh plumage.

MEASUREMENTS

	Wing	Bill (from skull)	Tail
1 ♂	115	15	70 mm
1 ♀	108	14	67 mm (HW)

A. Belly white; pale rufous wash across chest and flanks; upperparts pale sandy grey.....	<i>A. g. inconspicua</i> 44
B. Belly rufous; darkest and most richly coloured on upperparts. Wing male c. 91-102; female 88-92 mm.....	<i>A. g. australis</i> 47
C. Belly rufous; upperparts not so dark as next. Wing averages smaller; male c. 88-95; female 82-89 mm.....	<i>A. g. gulgula</i> 46
D. Belly white or paler than last two; upperparts darker above than last but not so dark as <i>australis</i> . Wing averages larger; male c. 96-105; female 90-99 mm.....	<i>A. g. temnyi</i> 48
E. Not so heavily streaked and much greyer than B, C, or D	
1 Wing averages larger: male c. 101-112; female 92-101 mm.....	<i>A. g. inopinata</i> 45
2 Similar in coloration to last except in fresh plumage when it is a little darker and slightly more rufous. Wing averages smaller: male c. 98-108; female 92-96 mm.....	<i>A. g. thamarum</i> 44

¹ Identified earlier as *A. a. intermedia* Swinhoe (Whistler, JBNHS 42: 729-30).

ALAUDIDAE

42

903. *West Siberian Skylark. Alauda arvensis dulcivox* Brooks

Alda Dulcivox Brooks, 1873, Stray Feathers 1: 484 ('Himalayas and plains of North-Western Punjab', emended to Djarkent, Russian Turkestan by Vaurie, 1951, loc. cit.: 511)

Alda cinerascens Ehmcke, 1904, Jour. f. Orn.: 313 (Barnaul, west Siberia) Baker, FBI No. 1211, Vol. 3: 315

LOCAL NAME. *Bhārū* (Hindi).

SIZE. Sparrow +; length c. 18 cm (7 in.).

FIELD CHARACTERS. A dark-streaked sandy brown lark, mistakable for a pipit but of squatter build and with relatively short tail; also with outer rectrices white. A short crest visible more clearly when raised. Sexes alike. See Key to the Species, and Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Winter visitor, fairly common and abundant between November and March in West Pakistan and India—Baluchistan [valleys and plains: Quetta, Chagai (subspecies?), probably central Makran], Chitral, Gilgit, Punjab (NW. frontier districts), northern Kashmir, Himachal Pradesh, Haryana, and western Uttar Pradesh south to c. 28°N., Central Nepal—December (Fleming, 1969, JBNHS 65: 329). From plains level to c. 1500 m in winter; c. 3000 m and higher in summer. Affects grassy meadows and the neighbourhood of cultivation.

EXTRALIMITAL. Western Siberia, SE. Russia... south along the borders of Russian Turkestan through western and central Altai, western Tien Shan and Pamirs to N. Afghanistan. (For details see Vaurie, 1959, 2: 55-6.)

GENERAL HABITS, FOOD, VOICE and CALLS. As in the Small Skylark (907, 908), but song louder and more musical. Gregarious in winter; often large flocks. In song-flight does not hover with continuous quivering wing-beats like *A. gulgula* but with intermittent momentary pauses, more reminiscent of Sand Lark (*Calandrella raytal*, 891).

BREEDING. Extralimital. No authentic record of nesting within our limits. A full fledged young obtained by Fulton at c. 3300 m in Chitral in June (Perreau, JBNHS 19: 916), but no other evidence. 'All records of any *arvensis* breeding in Baluchistan are erroneous' (Ticehurst, ibid. 31: 874).

MUSEUM DIAGNOSIS. See Key to the Species. Besides the longer wing-tip *A. arvensis* differs from *A. gulgula* in having much more spotting on the breast.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
5 ♂♂	114-120	15-16	24-25	66-76 mm
9 ♀♀	104-120	14-16	24-25	61-70 mm (HW)

COLOURS OF BARE PARTS. Iris hazel or dark brown. Bill: upper mandible horny brown; lower yellowish horny. Legs and feet fleshy brown or yellowish brown.

ALAUDIDAE

44

Geographical variation in this species is clinal and single specimens notoriously difficult—often impossible—to identify subspecifically. Series in comparable plumages are not usually available, hence there has been much confusion in published literature concerning the taxonomy, nomenclature and ranges of the various races. The present arrangement also will doubtless need minor readjustments as more precise knowledge becomes available.

904. *Turkestan Small Skylark. Alauda gulgula inconspicua* Severtzov

Alda inconspicua Severtzov, 1873, Verh. Turkest. Zhivotn.: 142 (Turkestan)

Alda gulgula punjaubi Whistler, 1936, Jour. Bombay nat. Hist. Soc. 38: 767 (Ferozepore, Sutlej River)

Baker, FBI No. 1219, Vol. 3: 322

LOCAL NAMES. *Bhārū*, *Chāndīl* (Hindi).

SIZE. Sparrow +; length c. 17 cm (6½ in.).

FIELD CHARACTERS. As in the nominate race (907), q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident, subject to local migratory and nomadic movements. Baluchistan (breeding below c. 2000 m), Sind, Gujarat (including Kutch and Saurashtra), Rajasthan, Haryana, and eastward through southern Uttar Pradesh and Bihar to about long. 85°E. (Dinapore), intergrading marginally with adjacent populations. Affects open grassy and cultivated areas.

EXTRALIMITAL. Iran, Afghanistan, Transcaspiia and Russian Turkestan.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 907.

BREEDING. Season (in Baluchistan), May-June. Nest, site, eggs (normally c/3), and breeding biology, as in the nominate subspecies.

MUSEUM DIAGNOSIS. Differs from *A. g. gulgula* (907) in its markedly paler coloration, both above and below, in fresh as well as worn plumage. Above, pale fringes to feathers of upperparts colder in tint; dark central streaking narrower and less intense. Below, buff not extending from breast to vent, but largely replaced by white on abdomen. Size slightly larger.

MEASUREMENTS

	Wing	Bill (from skull)
♂♂	90-101	16-17 mm
♀♀	86-98	15-17 mm

(HW, CBT)

Weight 19 ♂♂ 24-30; 7 ♀♀ 24-29 g (Paludan, Afghanistan). 4 ♂♂ 24-30 g (SA., Bharatpur).

905. *Kashmir Small Skylark. Alauda gulgula thamarum*

R. & A. Meinertzhagen

Alda arvensis thamarum R. & A. Meinertzhagen, 1926, Bull. Brit. Orn. Cl. 46: 100 (Ladak)

Alda guttata Brooks, 1872, Jour. Asiat. Soc. Bengal 41: 84 (Kashmir) nec *Alda guttata* Lafrenaye, 1839, Rev. Zool.: 259

Baker, FBI No. 1214, Vol. 3: 318

LOCAL NAME. *Bhārū* (Hindi); *Dider*, *Didra* (Kashmiri).

SIZE. Sparrow +; length c. 17 cm (6½ in.).

FIELD CHARACTERS. As in the nominate race (907), q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident, subject to seasonal local migratory and nomadic movements, altitudinal as well as spatial. The western Himalayas in Gilgit, Baltistan, Ladakh, Zaskar, rest of Kashmir, Himachal Pradesh (Spiti, Lahul), Garhwal, Kumaon and Nepal (winter visitor to the Valley). Breeding in summer from c. 1600 m in Kashmir up to c. 4300 m in Ladakh (Indus, Nubra, Dras and Suru valleys). Affects grassy margs, upland pastures, newly ploughed fields and cultivation, etc.

Extralimital. Pamirs.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 907.

BREEDING. Season, May to July. Nest and eggs (c/3 or 4) as in the nominate race. Average size of 41 eggs 23.1 x 16.3 mm (Osmaston). Site usually a grass meadow or a lucerne or young barley field.

MUSEUM DIAGNOSIS. Similar to *A. g. gulgula* (907) but larger, darker, and less rufous on the upperparts. Spotting on breast larger, more blackish and with a tendency to coalesce at the sides in a large black spot. Differs from *inconspicua* (904) in being darker, browner and less sandy; more heavily and broadly dark-streaked on the upperparts.

MEASUREMENTS

	Wing	Bill (from skull)
♂♂	98-108	13-16 mm
♀♀	93-97	14-15 mm (HW)

COLOURS OF BARE PARTS. As in 907 and other races.

906. Tibetan Small Skylark. *Alauda gulgula inopinata* Bianchi

Alauda japonica inopinata Bianchi, 1905, Ann. Mus. St Pétersbourg
9: 24, 30, 31 (Tibet)

Baker, FBI No. 1212, Vol. 3: 316

LOCAL NAMES. Cho-mo, Nam-che = 'sky bird' (Tibet).

SIZE. Sparrow +; length c. 17 cm (6½ in.).

FIELD CHARACTERS. As in the nominate race (907), q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Breeds in SE. Tibet and NEFA (?). Winter visitor to Nepal, Darjeeling dist. (northern W. Bengal), Sikkim, Bhutan, northern Assam plains. Affects upland pastures, moist grassland, and cultivation.

Extralimital. Northern Kansu, southwestward through Tsinghai and Sikang (south to northern Yunnan) to S. Tibet. In winter also to N. Burma (Vaurie).

GENERAL HABITS, FOOD, VOICE and CALLS. As in 907.

BREEDING. Extralimital. As in 905 and other races.

MUSEUM DIAGNOSIS. Larger than *thamum* (905) and duller, less dark and rufous in fresh plumage.

dangling loosely below — singing as he mounts higher and higher till almost lost to sight. He remains suspended in the heavens more or less stationary at this pitch, hovering on vibrating wings and wafted here and there by the wind, while he continues to pour forth an unbroken torrent of spirited loud and clear melodious warbling. This exuberant performance may last for over ten minutes without an instant's pause; at the end of it the singer closes his wings and drops like a stone for some distance, opens them out to hover a little, drops once more, and so on step by step, until when within a few metres of the ground he flattens out at a tangent and lightly comes to rest near the starting-point. Several birds frequently perform over the same bit of grassland as if in vocal rivalry. Snatches of the song sometimes also delivered from a perch on a clod or stone. Both song-flight and song very similar to those of Singing Bush Lark (872) and Sykes's Crested Lark (902) and may be easily confused with either when the bird is soaring aloft.

VOICE and CALLS. Song as above — a sustained, continuous, melodious warbling, interlarded (perhaps less freely than in the other two) with convincing mimicry of the calls of numerous other birds.

FOOD. Weed seeds, tiny root bulbs and insects; frequently some grit present in stomachs.

BREEDING. Season, overall March to August, principally April, May and June. Nest, a cup-like scrape or depression in the ground lined with grass, under shelter of a clod or grass-tuft in cultivation or grassland. Eggs, 3, sometimes 2 and rarely 4, rather variable in colour, usually greyish- or yellowish white densely and finely spotted with yellowish brown or purplish brown. Average size of 65 eggs 20.6 x 15.3 mm (Baker). Both sexes share all the domestic chores. Period of incubation undetermined.

MUSEUM DIAGNOSIS. See keys to the Species and Subspecies, and Field Characters; for details of plumage Baker, loc. cit.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	87-93	14-16	22-26	49-56 mm
♀♀	82-88	13-15	21-25	49-51 mm (HW)

COLOURS OF BARE PARTS. Iris hazel brown. Bill: upper mandible horny brown, lower pinkish flesh; mouth pink, or yellowish flesh. Legs, feet, claws brownish flesh colour.

908. Nilgiri Small Skylark. *Alauda gulgula australis* Brooks

Alauda australis Brooks, 1873, Stray Feathers 1: 486 (Ootacamund, Nilgiris)
Baker, FBI No. 1216, Vol. 3: 320

LOCAL NAMES. Bhārdī (Hindi); Bhārdīa pitta, Niala pichikā (Telugu); Vāndāmbādi kūrū (Telugu); Vānampākkilī (Malayalam); Gomarittā (Sinhala).

FIELD CHARACTERS. As in 907, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident. Nilgiri, Palni and associated hills, Kerala, and Ceylon in the Hill zone of Central and Uva Provinces. From the coastal plain (in Kerala) to at least c. 1600 m. Two specimens

MEASUREMENTS

	Wing	Bill (from skull)	Tail
8 ♂♂	102-108	15-16	60-68 mm
3 ♀♀	96-99	15-16	54-60 mm (Kinnear, BB)

COLOURS OF BARE PARTS. As in 907 and other races.

907. Indian Small Skylark. *Alauda gulgula gulgula* Franklin

Alauda gulgula Franklin, 1831, Proc. Zool. Soc. London: 119
(The Ganges between Calcutta and Benares)

Baker, FBI No. 1215, Vol. 3: 319
Plate 64, fig. 22

LOCAL NAMES. Bhārdī (Hindi); Jhūnti bhārdī (Bengali); Bārdīa pitta (Telugu); Vāndāmbādi kūrū (Tamil); Gomarittā (Sinhala).

FIELD CHARACTERS. Above, brown, each feather centred blackish and edged tawny. An indistinct tuft on crown, visible more clearly when partially erected. Below, pale fulvous-buff; darker fulvous on breast, faintly streaked and spotted with blackish. Sexes alike. See Museum Diagnosis.

Doubtfully distinguishable from Siberian Skylark (903), but is slightly smaller with the markings on breast less prominent and outer rectrices rufescent-white *contra* pure white. When crest invisible can be told from Indian Pipit (1859, 1860), also confusingly similar, by the lark's somewhat dumpy build, relatively shorter tail, and more crouching stance on ground.

STATUS, DISTRIBUTION and HABITAT. Resident; subject to some seasonal local movements. Peninsular India south of the range of *inconspicua* (excluding that of *australis*, q.v.), i.e. from northern Maharashtra (c. 20°N.) to Mysore, east through Tamil Nadu, Andhra, Madhya Pradesh, Orissa, Bihar (east of c. 85°E.), Nepal (Fleming & Traylor, 1961, *Fieldiana*, Zool., 35: 474), West Bengal, Assam and East Pakistan; plains and foothills. Also Ceylon, in the low country. Peripheral intergrading with adjacent populations renders exact boundaries undefinable. Affects damp open grassland on the edge of tanks and jheels, young wheat fields and ground crops (lucerne, gram, vetches, etc.), stretches of rank grass bordering salt pans and tidal mudflats in coastal tracts; even maidans and playing fields in built-up urban localities.

Extralimital. Northern Burma.

GENERAL HABITS. Keeps in twos and threes or small scattered parties running about on grassland in short spurts with the typical crouching gait of larks. When approached, squats tight making full use of its obliterative coloration, springing up suddenly when almost trod upon, to fly away with its characteristic fluttering undulating flight. The skylark's chief claim to distinction is in its remarkably lively, beautiful and sustained aerial song. It is delivered by the male chiefly in the breeding season but sporadically also throughout the year. From a perch on a clod or stone, the bird soars almost vertically up on rapidly quivering wings — legs

identified from Hyderabad and Chanda in south Deccan (Whistler, JBNHS 36: 913-14). Affects damp grassy tank margins, rolling downs and grassy rounded hilltops, e.g. in Nilgiris, Kerala, Ceylon; cultivation environs, dry paddy stubbles in coastal and backwater areas (Kerala).

GENERAL HABITS, FOOD, VOICE and CALLS. As in 907 and other races.

BREEDING. Season, chiefly November to April/May; in Ceylon chiefly March and April. Nest, site, and eggs (normally c/3) and breeding biology as in the nominate race. Average size of 20 eggs 21.7 x 15.9 mm (Baker).

MUSEUM DIAGNOSIS. Differs from nominate *gulgula* (907) in being larger and darker, with the upperparts brighter and more rufous; from *inconspicua* by darker coloration.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	90-102	14-17	22-26	49-56 mm
♀♀	84-93	13-17	22-25	48-54 mm (HW, SA)

COLOURS OF BARE PARTS. As in 907 and other races.

909. Yunnan Small Skylark. *Alauda gulgula vernayi* Mayr

Alauda arvensis vernayi Mayr, 1941, Ibis: 375 (Changyinkhu, Burma-Yunnan border)
Not in Baker, FBI

LOCAL NAMES. None recorded.

SIZE. Sparrow; length c. 15 cm (6 in.).

FIELD CHARACTERS. As in 907, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Winter visitor? Eastern Bhutan and NEFA in the hills above c. 1600 m.

Extralimital. Southern Tibet, northern Burma, Yunnan.

GENERAL HABITS, FOOD, VOICE and CALLS. Presumably as in 907 and other races.

BREEDING. Extralimital? Not recorded. May breed in the Assam hills north of Brahmaputra river.

MUSEUM DIAGNOSIS. A very dark and richly coloured race with broad and heavy markings, darker and more rufous than *thamum* or *inopinata* (Vaurie).

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	96-105	14-16	25-27	58-68 mm
♀♀	90-98	c. 15	25-26	54-65 mm (SA, Mayr)

Weight 4 ♂♂ 27-33; 2 ♀♀ 29, 29 g (SA).

COLOURS OF BARE PARTS. Not recorded. Doubtless as in 907.

LOCAL NAMES. Not recorded.

SIZE. Sparrow —; length c. 13 cm (5 in.).

FIELD CHARACTERS. As in 910, q.v.

x c. 1

STATUS, DISTRIBUTION and HABITAT. Not uncommon but sporadic. Resident and partly migratory. Assam and adjoining areas of East Pakistan (Sylhet); NEFA (?); Nagaland (?), Manipur. Affects open riverain tracts with vertical sandy banks to the streams.

Extralimital. Transbaikalia eastward to Amurland and N. Japan. In winter Thailand, Burma, Indochinese countries, etc. (For details see Vaurie, 1959, 2: 3.)

GENERAL HABITS, FOOD, VOICE and CALLS. As in 910.

BREEDING. Season, in Assam October–November with a recrudescence in March and April. Nest and eggs (c/4–6) as in 910. Average size of 20 eggs 17.5 × 11.9 mm (Baker). Baker found both species of *Riparia* nesting in the banks of Brahmaputra river at Dibrugarh, but each species kept entirely to itself and he never noted mixed colonies.

MUSEUM DIAGNOSIS. See Key to the Subspecies.

MEASUREMENTS

SIZE. Sparrow —; length c. 12 cm (4½ in.).

50

HIRUNDINIDAE

breast; sides of neck, throat and flanks more or less suffused with smoky grey. Sexes alike.

Young (immature). Feathers of upperparts conspicuously edged with pale rufous; chin and throat fulvous.

STATUS, DISTRIBUTION and HABITAT. Widely but sporadically distributed; partly migratory, partly resident; subject also to considerable local movements as yet little understood. Baluchistan, Sind, NW. frontier districts of West Pakistan, Kashmir, Ladakh (?), Himachal Pradesh, Haryana, Uttar Pradesh, Nepal (?), Bihar, northern West Bengal and Bhutan: plains level to c. 4500 m. Breeds over most of this range. Affects the neighbourhood of large streams and rivers with vertical earth cliffs affording potential nesting sites.

Extralimital. SW. Siberia, E. Iran, Afghanistan, Russian Turkestan, NE. China, Burma, etc. (For details see Vaurie, 1959, 2: 4.)

GENERAL HABITS. Highly gregarious. Keeps in large flocks of 50 to a hundred birds or more, often in association with Cliff and other swallows and swifts. Huge congregations collect at reed-bed roosts (sometimes shared with swallows) and for colonial nesting. The birds fly about individually and in scattered parties, sometimes quite high up in the air, hawking insects in open riverain tracts, by marshes and tanks, or above fired grass fields. Commonly seen perched in long close-packed rows along telegraph wires sunning and preening themselves in the morning.

FOOD. Insects: Diptera and small beetles (Coleoptera) etc. taken on the wing.

VOICE and CALLS. When flying around nest colony, a hard *ret* or *errit*. Song, a short grating twittering.

BREEDING. Season, November to May, chiefly February to April. Nest, a pad of dry grass, straw and roots lined with a few feathers. Placed at the end of a horizontal tunnel often a metre or more deep; in large colonies, often a hundred holes or more honeycombing steep sandy banks of rivers; sometimes in company with Bank Mynas. An occupied colony presents a scene of great bustle and activity, the birds clinging to the cliff face or fluttering outside the holes, constantly coming and going and flying around uttering twitters and chirrups. Eggs, 3 or 4, glossless pure white, small replicas of those of the House Martin (*Delichon*). Average size of 40 eggs 16.5 × 12.1 mm (Baker). Both sexes partake in digging the tunnel and incubation. Incubation period undetermined.

MUSEUM DIAGNOSIS. See Field Characters and Key to Subspecies; for details of plumages and morphology (also bionomics) of the extralimital nominate race — which is darker on the underparts and with a more clear-cut breast-band — Witherby *et al.*, 1938, 2: 239–42.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♂ (99)	102–108	c. 6	c. 10	46–51 mm
♀ ♀	102–108			(Baker, SA)

† The material of the nominate race is methodical of the two of confusion and ambiguity.

52

- HIRUNDINIDAE

FIELD CHARACTERS. Similar to 910 but somewhat smaller and without the dark breast-band.

Adult. Above, greyish brown, rather darker on crown and paler on rump; wing-quills and tail darker brown. Below, chin to lower breast smoky grey; rest of underparts white. Sexes alike.

Young (immature). Feathers of upperparts, wings and tail broadly margined with pale rufous. Grey of throat and breast paler.

STATUS, DISTRIBUTION and HABITAT. Resident, subject to local movements. Indian range largely overlapping that of Collared Sand Martin (910, 911), but see footnote under 910. West Pakistan (Baluchistan, Sind, Punjab) and northern India from the Himalayan foothills including Nepal (terai, Kathmandu Valley, etc.), Bengal duars, Bhutan foothills (?); south through Rajasthan, Gujarat and Maharashtra to Bombay, Nasik, Satara (c. 18°N.), etc., east through Madhya Pradesh and Orissa to Assam and East Pakistan. Affects riverain tracts with vertical sandy banks along the streams, and alluvial cliffs — potential nesting-sites.

Extralimital. Russian Turkestan, E. Afghanistan, Burma, N. Thailand, S. Yunnan, the Indochinese countries, Formosa and N. Luzon. Resident or wandering locally (Vaurie). Other races in Africa.

GENERAL HABITS, FOOD, VOICE and CALLS. As in Collared Sand Martin (910), q.v.

BREEDING. Season, over most of its Indian range October to February. Rarely, as in Assam, a second brood may be raised in April and May (Baker). Nest and eggs (c/2–4; in Assam 5–6) as in 910. Average size of 100 eggs 17 × 12 mm (Baker).

MUSEUM DIAGNOSIS. See Key to the Species.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	90–96	c. 8	10–11	37–45 mm (SA, GD)

Weight 1 ♂ 10; 2 ♀ ♀ 9.5, 10 g (GD).

COLOURS OF BARE PARTS. Iris dark brown. Bill black. Legs and feet dark brown.

Genus *HIRUNDO* Linnaeus

Hirundo Linnaeus, 1758, Syst. Nat., ed. 10, 1: 191. Type, by subsequent designation, *Hirundo rustica* Linnaeus

Cecropis Boie, 1826, Isis (10), col. 971. Type, by subsequent designation, *Hirundo capensis* Gmelin = *Hirundo cucullata* Boddaert

Pyronoprogne Reichenbach, 1850, Syst. Av., Pl. 67, fig. 6. Type, by monotypy, *Hirundo rupestris* Scopoli

Erimachelidon Walden, 1876, Ibis: 356. Type, by subsequent designation, *Hirundo concolor* Sykes (Baker, 1930, FBI 7: 255)

Comprises the true swallows. Bill short, wide at gape, flat and triangular. Tarsi and feet unfeathered. Wings very long and pointed reaching beyond angle of tail-fork. In the majority upperparts deep glossy steel-blue and tail deeply forked, the lateral pair of rectrices greatly elongated, with the terminal half attenuated. In some (Crag Martins) upperparts dull brown and tail nearly square or only slightly forked as in *Riparia* but always showing white spots on rectrices. Nests built of mud, attached to substrate.

913. Crag Martin. *Hirundo rupestris* Scopoli*Hirundo rupestris* Scopoli, 1796, *Annus I*, Hist. Nat.: 167 (Tyrol)

Baker, FBI No. 1149, Vol. 3: 236

Plate 65, fig. 5

LOCAL NAMES. Not recorded.

SIZE. Sparrow; c. 14 cm (5½ in.).

FIELD CHARACTERS. Very like Dusky Crag Martin (914), q.v. Slightly larger and paler (ashy brown) above, with much paler (almost whitish) underparts and blackish under tail-coverts, clearly contrasting in overhead flight. Sexes alike.

Young (immature) has feathers of upperparts margined with rufous. Entire underparts pale dull rufous. (For details see Museum Diagnosis.)

STATUS, DISTRIBUTION AND HABITAT. A montane form, breeding in the Himalayas in West Pakistan (Rawalpindi and Peshawar dists.), and through Chitral, Gilgit, Ladakh, Kashmir, Himachal Pradesh, Garhwal, Kumaon, Nepal, Sikkim (?), and Bhutan, between 1600 and 5000 m. Also in northern Baluchistan (Quetta and Ziarat dists.) between 2000 and 3500 m. Winters throughout the hilly portions of the Indian subregion (Sahyadris or Western Ghats, Satpuras, Nilgiris, Palnis and other peninsular hills) — south to Mysore and Tamil Nadu; probably also Kerala whence not yet recorded. Records from eastern parts of the Peninsula scarce or lacking. Affects grassy hills with crags and precipices; is a regular *habitué* of ancient hill-forts.

SWALLOWS

55

914. Dusky Crag Martin. *Hirundo concolor concolor* Sykes*Hirundo concolor* Sykes, 1833, Proc. Zool. Soc. London: 83 (Dukhun)

Baker, FBI No. 1150, Vol. 3: 237

Plate 65, fig. 6

LOCAL NAMES. *Chātān ābābil* (Hindi); *Katrikappakshi* (Malayalam).

SIZE. Sparrow —; length c. 13 cm (5 in.).

FIELD CHARACTERS. A sooty brown swallow with short square-cut tail. Underparts only slightly paler than upper; chin, throat and foreneck dull rufous finely streaked with blackish. A roundish white spot on all tail-feathers except the middle and outermost pairs, conspicuous when the bird banks or wheels in flight. Sexes alike.

Similar to 913 but somewhat smaller and with darker underparts.

STATUS, DISTRIBUTION AND HABITAT. Resident. Widely but patchily distributed, and subject to local movements. Along the base of the Himalayas and southward through the entire Peninsula to extreme Tamil Nadu and Kerala. From Haryana, Rajasthan, N. Gujarat and Kutch, in the west, to Bihar and West Bengal in the east. Plains and hills to at least 1800 m. Affects the neighbourhood of rocky hills with crags and ancient fortifications; old buildings, preferably of stone, deserted or occupied, even in the midst of noisy populous cities, e.g. Bombay.

Extralimital. A darker subspecies [*sintlaungensis* (Stuart Baker)] in Burma and N. Thailand.

GENERAL HABITS. Similar to those of the migratory species (913). Usually seen in pairs or small parties hawking insects round crags and old buildings, resting betweenwhites on ledges and cornices etc., sometimes even inside verandas. Very much at home among rock-cut caves and ancient hill-forts (e.g. Ajanta, Ellora, Daulatabad) and old buildings in deserted historical cities like Mandu in Madhya Pradesh, and Fatehpur Sikri.

FOOD, VOICE AND CALLS. As in 913.

BREEDING. Season, varies somewhat with locality, but over its range covers more or less the entire year except perhaps November and December; in two well-marked peaks February–March and July–August. Often two broods (or more?) raised. Nest, like that of 913 — a deepish oval saucer of mud, c. 12 cm long × 8 cm wide, attached bracketwise to a vertical wall or rock face, lined with fine grass, tow, and feathers. As a rule single; sometimes in a small scattered colony. Built under eaves, archways and road culverts, or against rafters in deserted or occupied dwellings, old mosques and tombs and on ceiling of rock-cut caves as well as on natural cliffs, usually sheltered by an overhang. Same site used in subsequent years, not necessarily by same pair. Eggs, 2 to 4, white, minutely speckled and spotted with various shades of reddish brown. Average size of 100 eggs 17.6 × 12.8 mm (Baker). Both sexes take part in nest-building, incubation, and feeding the young. Incubation period undetermined.

MUSEUM DIAGNOSIS. See Key to the Species.

Young (immature). Like adult but upperparts and wings narrowly margined with rufous-grey. Chin and throat paler, and dark streaks absent.

MEASUREMENTS	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	105–113	9–11	9–10	42–46 mm (SA, HW)

HIRUNDINIDAE

54

Extralimital. S. Europe, NW. Africa through C. Asia (including Iran and Afghanistan) to Manchuria. (For details see Vaurie, 1959, 2: 6.) Not recorded in winter in Burma or Thailand.

MIGRATION. No ringing data. By end of March has mostly departed from peninsular India. Arrives in Gilgit and Chitral between third week March and mid April; remains till October, breeding between c. 1600 and 4000 m (Scully, SF 10: 100; Fulton, JBNHS 16: 55; Perreau, *ibid.* 19: 914).

GENERAL HABITS. In its winter quarters keeps in loose parties, flying about scattered individually in company with Dusky Crag Martins and other swallows around and in the environs of crags and precipices, and ancient hill-forts. Flight swallow-like — flaps interspersed with sailing glides and much agile banking and turning, punctuated by swoops to capture an insect, sometimes from near the ground or the surface of water; also drinking thus. Spends most of the day foraging on the wing; rests for short periods in between on ledges of rocky cliffs or fort walls. Roosts in company at night in similar situations.

FOOD. Dipterous insects, small flying beetles, etc.

VOICE AND CALLS. A soft low *chit-chit* uttered at rest and in flight. Song not recorded in India.

BREEDING. Season, April to June; at the highest elevations later and up to July. Nest, similar to the Western Swallow's (916), a deepish oval saucer of conglomerated mud pellets collected when wet; lined with grass and feathers. Attached like a bracket to a rock face, usually sheltered by an overhang. Built singly or in small colonies usually on inaccessible rocky cliffs and the vertical sides of narrow gorges, often directly over a stream. Eggs, 3 or 4, also like Swallow's — white boldly speckled and spotted with pale chocolate-brown with a few underlying purplish grey markings. Average size of 20 Indian-taken eggs 21.2 × 14.3 mm (Baker). Both sexes share in incubation and feeding the young. Incubation period undetermined.

MUSEUM DIAGNOSIS. See Key to the Species. A large white spot on inner web of all tail-feathers except the central and outermost pairs.

Young (immature). Like adult but upperparts and all coverts, except primary- and under-tail, with narrow rufous-ashy tips, more pronounced on rump and upper tail-coverts, tips of wing-coverts and tertials. White spots on rectrices smaller.

In contrast with other migratory swallows the adults moult before leaving the breeding area. For particulars of moult see Stresemann, E., & V., 1969, J. Orn. 110 (1): 39–42.

MEASUREMENTS

Weight 4 ♂ ♀ 12–14 g (SA).

COLOURS OF BARE PARTS. Iris brown. Bill blackish brown; mouth pinkish grey. Legs and feet pinkish brown; claws brown.

915. Pale Crag Martin. *Hirundo obsolata pallida* (Hume)*Pionoprogne pallida* Hume, 1872, *Stray Feathers* 1: 1 (Along the Gaj... Sindh...)

Kurachee... Mekan coast — Sind)

Baker, FBI No. 1151, Vol. 3: 238

Plate 65, fig. 4

LOCAL NAMES. None recorded.

SIZE. Sparrow —; length c. 13 cm (5 in.).

FIELD CHARACTERS. A sandy version of Dusky Crag Martin (914). Above, pale brownish grey; wings and tail darker. Below, rusty cream colour, more albescent on chin and throat. Sexes alike. Confusable with *H. rupestris* (913). See Key and Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident, subject to local movements. West Pakistan [Baluchistan, Sind (Khirthar range), and Punjab in the NW. frontier districts], breeding chiefly in the foothills and higher up. Also Kutch (Stoliczka), whence however not recently reported. Affects bare hilly country with crags and precipices.

Extralimital. Extends westward through S. Afghanistan and SE. Iran. Other races in Iraq, E. Arabia and N. Africa.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 913 and 914, q.v.

BREEDING. Season, nest and eggs apparently as in 914, but imperfectly known. 'Average size of [?] eggs 18.2 × 13.3 mm' (Williams, JBNHS 33: 606). Apparently breeding in Fort Munro and Quetta districts of Baluchistan, but the records equivocal. May breed in Khirthar hills of Sind.

MUSEUM DIAGNOSIS. Axillaries and under wing-coverts ashy brown, the latter with pale tips. Flanks, vent and under tail-coverts pale brownish grey, the last with pale tips. White 'mirrors' on all but central and outer pairs of rectrices towards the tips.

LOCAL NAMES. *Abūtil* (Hindi and Bengali — generally for all swallows, martins and swifts); *Katij* (Kashmir); *Kir kishi*, *Tetaki* (Brahui — Baluchistan); *Telci illātha kūrūri*, *Adai källān kūrūri*, *Tām-pādi* (Tamil); *Wārā kovela* (Telugu); *Peras pitta* (Gond); *Wēhi līhīniya* (Sinhala); *Veyalkūti* (Malayalam).

SIZE. Sparrow \pm , with long forked tail; overall length c. 18 cm (7 in.).

FIELD CHARACTERS. Adult. Glossy steel-blue above, pale pinkish white below with the typical deeply forked swallow tail (outer rectrices greatly elongated and attenuated on terminal half). Forehead, chin, and throat chestnut, the last bordered below by a blue-black pectoral or breast band. Sexes alike.

In banking flight white spots on tail-feathers (all but the central pair) clearly visible.

One half of tail: adult (left), juvenile (right) and right foot, $\times 1$

Young (immature) browner, less glossy above; pectoral band brown; chestnut parts much paler. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Breeds in Baluchistan north and west of a line from Gwadar (c. 25°N., 62°E.) to Sibi, Bannu, Chitral (probably also Gilgit and Ladakh), Kashmir (Srinagar Valley), Himachal

SWALLOWS

59

puddle while wet, drying to terracotta hardness; sometimes lined with grass and straw, and a few downy feathers. Attached like a bracket to a wall near the ceiling or side of a beam or rafters within a building, frequently a dwelling house or bazaar shop, within arm's reach of the human inmates. In Kashmir a favourite site is the beams under the hull of a houseboat just above water line. The same site, and often the same nest repaired, is used in successive seasons. Eggs, 4 to 6, white, dotted and speckled with reddish- or purplish brown, more densely at the broad end. Average size of 78 Kashmir eggs 19.6 \times 13.7 mm (Osmaston). Both sexes take part in building the nest and feeding the young. Incubation chiefly by female; period 14–16 days. Flying young commonly fed in mid-air.

MUSEUM DIAGNOSIS. For details of plumages and structure (also bionomics) see Witherby *et al.*, 1938, 2: 226–33. Differs from the eastern subspecies *gutturalis* (917) in having the blue-black pectoral band (below chestnut of throat) unbroken in the middle. Most dependable diagnostic character is the wing length: over 120 mm c. (usually) under 118 in *gutturalis*.

Young (immature). Like adult but upperparts, wings, and tail much less glossy; forehead nearly white; chin and throat pale rusty; pectoral band grayish black. Fork of tail less deep. Outermost pair of rectrices always broader than in adult.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail central outer
♂♂	120–129	10–12	10–13	93–122 mm
♀♀	116–128	—	—	40–48 76–107 mm

Outermost pair of rectrices usually broader in female than in male but sometimes equally narrow. (Witherby)

Weight 10 ♂♂ 16–22 (av. 18.1); 6 ♀♀ 16–20 (av. 18.3) g (Paludan).

COLOURS OF BARE PARTS. Iris dark brown. Bill, legs and feet black.

917. Eastern Swallow. *Hirundo rustica gutturalis* Scopoli

Hirundo gutturalis Scopoli, 1786, Del. Flor. et Faun. Insubr. 2: 95
 (New Guinea, *error*, Panay = Philippines, Hartert, 1910)
Hirundo rustica ambigua Stresemann, 1940, Orn. Monatsb. 48: 83 (Sikkim)
 Baker, FBI No. 1153, Vol. 3: 241

LOCAL NAMES. As for 916.

SIZE. Sparrow \pm , with long forked tail; overall length c. 18 cm (7 in.).

FIELD CHARACTERS. As in 916, q.v. Subspecies indistinguishable in the field. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Breeds in the Himalayas from Nepal (where it intergrades with nominate *rustica*) eastward through Darjeeling, Sikkim, Bhutan, and NEFA, to c. 3000 m; also in the Assam hills south of Brahmaputra river. Winters south to the extreme tip of the Peninsula and in Ceylon, largely overlapping the winter range of *rustica*. Winters also in the Laccadive, Maldiva, Andaman and Nicobar islands. Affects open country — cultivation, jheel environs, coastal backwaters, etc.

58

HIRUNDINIDAE

Pradesh, Garhwal, Kumaon and Nepal (Kathmandu Valley); plains and hills to c. 3000 m. Winters (c. September/October to March/April) more or less throughout the subcontinent, intermixed with the eastern subspecies *gutturalis* (917). Indistinguishable from the latter unless in the hand, and then only in good plumage. Affects open country, in the neighbourhood of rivers, jheels, cultivation and human habitations. A single record from Ceylon (Whistler, 1944: 190). In summer common around many west Himalayan hill-stations and upland villages.

EXTRALIMITAL. Europe north to between 60 and 70°N. (including Great Britain, Mediterranean countries and islands), and western Asia: Transcaucasia, Asia Minor, Iraq, E. Arabia, Iran, Afghanistan, Russian Turkistan. (For further details see Vaurie, 1959, 2: 9.)

MIGRATION. No ringing data. Begins arriving in Baluchistan and over most of its breeding range late February/early March, continuing into April. Autumn exodus commences by end August; the majority have departed for the wintering grounds by end September.

GENERAL HABITS. Highly gregarious in winter. When first arrived on migration, often seen in enormous close-packed swarms occupying long stretches of several strands of telegraph wires, widely scattered over the entire range, sunning themselves in the mornings. The restless congregation launches out in the air from time to time and gradually returns to the perch. Hawks winged insects usually low over meadows, standing crops, reed-beds, or open water in company with other swallows and swifts. Flight swift: a few rapid wing-beats followed by a graceful glide or swoop, with agile banking and turning movements. Loose parties beat back and forth over water, almost skimming the surface, with slow deliberate wing-beats as they fly upwind, scooping up floating insects. At the end of the beat the bird wheels round and shoots back non-stop downwind to the starting point. The slow upwind hunt is resumed, taking full advantage of the resistance to scan the surface. In upcountry towns and villages commonly seen hawking insects in congested bazaars among the bustling shoppers and traffic, the birds shooting up and down at high speed — almost skimming — close above the narrow horse-dung littered streets in pursuit of flies and midges, (clocked at 23–30 m.p.h.), twisting and turning adroitly, weaving in and out amongst tongas, loiterers, sacred cows and miscellaneous obstacles. Vast congregations collect to roost in partially submerged reed- and tamarisk beds, sugarcane fields, coastal mangroves, and the like, sometimes sharing these with wagtails and sand martins. The swallows arrive in the late gloaming looking like a dense swarm of midges, and after milling around high overhead for a few moments drop suddenly into the reeds, first by ones and twos, then by scores and hundreds, like thick flurries of falling leaves.

FOOD. Chiefly midges, gnats and other dipterous insects captured in the air or scooped off water; sometimes ants on the ground by alighting and shuffling about.

VOICE AND CALLS. Pleasant twittering notes uttered on the wing and while at perch. Song, a rather feeble musical twittering by male in the breeding season, lasting up to 15 seconds or more.

BREEDING. Season, chiefly mid April to end May. Nest, very like the Crag Martin's: a deepish saucer of conglomerated mud pellets collected at a

HIRUNDINIDAE

60

EXTRALIMITAL. Breeds in Tibet, Burma (?), China, Japan; winters over most of SE. Asia. For particulars see Vaurie, 1959, 2: 10.

MIGRATION. No ringing data in India. Arrives in Mysore and the Nilgiris between mid September and first week October (Betts); in Ceylon from 3rd or 4th week September (Phillips); in the Andamans about 3rd week September. Departs from the Andamans in April (Osmaston).

That our winter visitors may also derive from a very extensive area is suggested by the Eastern Swallows ringed in Bangkok City in winter from a single roosting congregation, recovered in such far-flung places as Siberia, North and South Korea, Taiwan and Malaya (McClure, H. E., 1968, Report No. FE-315-2, Migratory Animals Pathological Survey: 133).

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 916. Roosting in vast congregations on power transmission wires and pylons in suburban Bombay reported (George, P. V., JBNHS 62 (1): 160).

BREEDING. Season, May to June/July. Nest, eggs (c/4–6) and breeding biology as in 916.

MUSEUM DIAGNOSIS. Differs from nominate *rustica* (916) in having the blue-black pectoral band usually broken in the middle or with the chestnut of throat encroaching on it. Best diagnostic character is the shorter wing, usually under 118 mm.

Young (immature) recognizable from juvenile *rustica*, on a series, by the pectoral band not being so solidly dark, and the underparts whiter, not pale buff (Ticehurst, 1938: 623).

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail central outer
♂♂	110–123	11–12	9–13	27–46 72–96 mm
♀♀	108–113	11–13	10–13	39–55 67–73 mm

Weight 36 ♂♂ (possibly mixed with some *rustica*) 12–20 (av. 16) g — SA.

COLOURS OF BARE PARTS. As in 916.

918. Tytler's or Chestnutbellied Swallow. *Hirundo rustica tytleri* Jerdon

Hirundo Tytleri Jerdon, 1864, Bds. India 2 (3): 870 (Dacca)
 Baker, FBI No. 1154, Vol. 3: 242
 Plate 65, fig. 12

LOCAL NAMES. As for 916 where applicable. *Lāl ātāhī* (Bengali).

SIZE. Sparrow \pm , with long forked tail; overall length c. 18 cm (7 in.).

FIELD CHARACTERS. As of 916, q.v., but entire underparts chestnut instead of pinkish white. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Irregular winter visitor abounding in some years, scarce or absent in others — Bhutan, NEFA, Assam, Nagaland, Manipur and East Pakistan. Common and regular in winter at the Salt Lakes near Calcutta along with *rustica* and *gutturalis* (BB). Affects open well-watered country, cultivation, broad sandy river banks, etc.

EXTRALIMITAL. Winters also in northern Burma. Breeds in extreme NE. Asia and Kamchatka.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 916. On Logtak Lake, Manipur, large numbers observed in January roosting together with *H. r.*

SWALLOWS

61

gutturalis on loosely drifting rafts of water hyacinth (*Eichhornia*) on open water. Hawking insects commenced in the misty morning as soon as there was sufficient light (SA).

BREEDING. Extralimital. Breeding biology as in 916, 917.

MUSEUM DIAGNOSIS. See Field Characters and Key to the Subspecies.

Upper plumage glossed with purple-blue; bill much larger.....

..... *H. t. javanica*

Upper plumage glossed with green; bill much smaller... *H. t. domicola*

919. Nilgiri House Swallow. *Hirundo tahitica domicola* Jerdon

Hirundo domicola Jerdon, 1844, Madras Jour. Lit. Sci. 13: 173 (Nilgiri Hills)
Baker, FBI No. 1156, Vol. 3: 244
Plate 65, fig. 13

LOCAL NAMES. Kānāvārikakkili (Malayalam); Wēhi lūhinyā (Sinhala); Tāmpādi Talai illāda kūrūri (Tamil).

SIZE. Sparrow —, with deeply forked tail; length c. 13 cm (5 in.).

FIELD CHARACTERS. Adult. Above, forehead chestnut; rest of upperparts, including deeply forked tail, black with a metallic green gloss. Below, chin, throat and upper breast chestnut; rest of underparts pale ashy. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Resident; largely sedentary. Hills of southwest India from the Nilgiris southward through Kerala, and Ceylon; from c. 700 to 2400 m. In Ceylon visits the Wet zone foothills to as low as 300 m when not breeding (Phillips). Affects grassy hill slopes around tea and coffee plantations and the proximity of bungalows, factory sheds, labour barracks, etc.

GENERAL HABITS, FOOD, VOICE AND CALLS. Similar to 916. Parties frequently seen perched huddled together on bare upper branches of dead trees in clearings. Tame and confiding, nesting freely within inhabited bungalows and sheds, flying in and out of verandas and living-rooms regardless of noisy inmates and blaring radios. Flying juveniles fed by parent in mid-air, both birds fluttering and halting momentarily while food transferred to youngster's gape.

BREEDING. Season, in S. India chiefly March to May; in Ceylon December to June, chiefly February to April. Nest, a half-saucer of mud pellets, as in 916, attached to wall or rock-face, under road culverts or in tunnels; most commonly under eaves or against ceiling beams and rafters in houses; sometimes two or three nests in the same shed or veranda. Same site and nest (repaired if necessary) often used year after year. Eggs, 2 or 3, very

921. Indian Wiretailed Swallow. *Hirundo smithii filifera* Stephens

H. (irundo) filifera Stephens, 1825, in Shaw's Gen. Zool. 13: 78 (India, ex Latham)
Hirundo smithii bobrikskoi Stachanow, 1930, Orn. Monatsb. 38: 76 (Tchubek, Bokhara)
Baker, FBI No. 1157, Vol. 3: 245
Plate 65, fig. 9

LOCAL NAME. Leishra (Hindi).

SIZE. Sparrow ±; length c. 14 cm (5½ in.) excluding tail-wires.

FIELD CHARACTERS. Adult. Glossy steel-blue above, with a bright chestnut cap. Readily distinguished from other swallows both at rest and in flight by glistening pure white underparts and two long fine 'wires' projecting from tail. Sexes alike, but tail-wires of female shorter.

STATUS, DISTRIBUTION AND HABITAT. Summer (breeding) visitor to the cold-winter parts of W. Pakistan and northern India — northern Baluchistan, upper Sind, NW. frontier districts, Punjab, Kashmir, Himachal Pradesh, etc. Also Nepal, Sikkim, Bhutan and NEFA (?). Normally to c. 1500 m in the Himalayas, but has been recorded breeding up to c. 2700 m, above Chakrata [Vaid, 1965, *Indian Forester* 91(11)]. Resident elsewhere in the Peninsula subject to local movements, east to Assam and E. Pakistan, breeding south to N. Kerala (Cannanore dist.) and the Nilgiris. A straggler recorded in Ceylon (Wynell-Mayow, 1966, JBNHS 63: 442). Affects open country, cultivation and habitations essentially in the neighbourhood of water — rivers, jheels, reservoirs, etc.

Extralimital. Russian Turkestan, Afghanistan, Burma, N. Thailand, Laos, central Vietnam. Nominate *smithii* in tropical Africa.

GENERAL HABITS. Similar to other swallows, cf. 916, but is more narrowly attached to the vicinity of water; rarely met away from canals, jheels, reservoirs and the like. Loose parties skim the water surface or shoot along close to the ground over adjacent meadows or cultivation, hawking insect prey. Flight swift — a few rapid wing-flaps punctuated with graceful swoops and glides and agile turning and banking movements. Roosts in partially submerged tamarisk- and reed-beds in association with wagtails, reed warblers and other swallows.

FOOD. Small flying insects, mainly midges, gnats and other Diptera; winged ants and termites, etc.

VOICE AND CALLS. A cheerful low *chit-chit* while flying about. Song of male, a musical twittering double *chirik-weet*, *chirik-weet* repeated every two seconds or so from perch near nest. A sharp angry *chichip*, *chichip*, reminiscent of wagtail's, by way of 'war cry' while attacking an intruder, e.g. nest-pirating sparrow.

BREEDING. Season, overall March to September, the principal periods varying locally. Nest, as of Crag Martin or Swallow, an oval mud saucer c. 13 × 8 cm, lined with fine grass and feathers, attached bracketwise to a vertical surface, e.g. wall or rafter in a veranda, under arch of bridge or culvert, or under rock overhang flanking a stream. In the last situation often less than a metre above the water, and frequently in proximity of nest of Large Pied Wagtail which builds in identical situations. Wet mud collected by the birds at a puddle and plastered on substrate very gradually, pellet by pellet, to allow for hardening into a firm foundation; thus nest may take

62

HIRUNDINIDAE

like Crag Martin's or Western Swallow's, white, minutely spotted and speckled with various shades of reddish brown. Average size of 50 eggs 17.4 × 12.5 mm (Baker). Both sexes take part in nest-building, incubation, and feeding the young. Incubation period undetermined.

MUSEUM DIAGNOSIS. Differs from *H. t. javanica* (920) in having a smaller bill, and upper plumage glossed with green v. purple-blue.

Young (immature). Like adult but upperparts less metallic; chestnut forehead less defined. Chestnut of chin, throat, and breast softer and paler; rest of underparts faintly washed with pinkish white. Tertiaries and their coverts, and under tail-coverts broadly edged at tips with pinkish white. Outer rectrices blunter at tip than in adult.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail (outer)
♂ ♀	99-105	10-11	c. 11	44-47 mm (SA)

Breadth of bill at forehead c. 6 mm (Baker).

COLOURS OF BARE PARTS. Adult. Iris brown. Bill brownish black; mouth yellowish pink. Legs and feet horny brown; claws like bill. Immature. Iris brown. Bill horny brown, yellow near gape; mouth and gape yellow. Legs and feet pinkish brown; claws horny brown.

920. Javan House Swallow. *Hirundo tahitica javanica* Sparrman

Hirundo javanica Sparrman, 1789, Mus. Carls., fasc. 4, pl. 100 (Java)
Baker, FBI No. 1155, Vol. 3: 243

LOCAL NAMES. None recorded.

SIZE. Sparrow ±; length c. 14 cm (5½ in.).

FIELD CHARACTERS. As of 919, q.v. See Key to the Subspecies.

STATUS, DISTRIBUTION AND HABITAT. Breeding, and apparently resident: Andaman Islands. Not recorded in the Nicobars. Affects open country along sea coast.

Extralimital. Southern Burma from Arakan to Tenasserim. The species ranges over Malay Peninsula and Indonesia.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 916 and 919, qq.v.

BREEDING. Season, in Andamans, as yet known, May and June. Nest and eggs (c/2-4) as in 919. Built in verandas of houses (Port Blair, Butler, JBNHS 12: 557) and caves on the shore (North Button I., Osmaston, ibid. 17: 161). Average size of 40 eggs 17.5 × 12.7 mm (Baker).

MUSEUM DIAGNOSIS. See Key to the Subspecies.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	97-107	c. 10.5	c. 10-12	— mm

Breadth of bill at forehead c. 7.5 mm.

(Baker)

COLOURS OF BARE PARTS. Iris dark brown. Bill black. Legs and feet brownish black.

HIRUNDINIDAE

64

over a week to complete. Nest usually single; occasionally several close to one another but not clustered. Same site and nest (repaired or rebuilt) used year after year; two, sometimes three, successive broods raised in a season. In urban localities even occupied nests frequently usurped by House Sparrows. Eggs, 3 to 5, very like Western Swallow's, white or pinkish white minutely speckled and spotted with reddish brown. Average size of 120 eggs 18.4 × 13.1 mm (Baker). Both sexes partake in building the nest and feeding the young. Flying young fed in mid-air. Incubation apparently by female alone: 14 or 15 days. Young leave nest on 15th or 16th day but return to it to roost at night until driven off by hostile demonstrations and 'war cries' of the parents wanting it for the next brood.

MUSEUM DIAGNOSIS. See Key to Species.

Young (immature). Crown paler and browner; upperparts dull sooty brown, showing the steel gloss in patches here and there. No wires in tail. Underparts tinged with fulvous. Fledgling leaves nest in this dress, which is retained till it moults into adult plumage.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail central outer (including 'wire')
♂ ♂	113-122	11-12	9-11	30-36 109-173 mm
♀ ♀	108-116			30-36 51-71 mm (SA, HW)

COLOURS OF BARE PARTS. Iris brown. Bill blackish brown; mouth pale lemon-yellow. Legs, feet and claws blackish brown.

922. Indian Cliff Swallow. *Hirundo fluvicola* Blyth

Hirundo fluvicola Blyth, 1855, Jour. Asiat. Soc. Bengal 24: 470 (Bundelkund ex Jerdon)
Baker, FBI No. 1158, Vol. 3: 246
Plate 65, fig. 17

LOCAL NAMES. Nāhār ābābil (Hindi); Bhākhād ābābil (Gujarati).

SIZE. Sparrow —; length c. 12 cm (4½ in.).

FIELD CHARACTERS. A small swallow with a very slightly forked tail. Above, glossy steel-blue with dull chestnut forehead and crown, and pale brown rump. Below, fulvous white, profusely streaked with blackish on sides of head, chin, throat and breast. Sexes alike.

For young see Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Status unclear; apparently, like Wiretailed Swallow, a summer (breeding) visitor — end February to September — to cold-winter areas in northern W. Pakistan and NW. India. Elsewhere resident — common in the Gangetic Plain — but with marked local movements: east and south of a line from about Rawalpindi through Sambhar Lake (Rajasthan) to the Gulf of Cambay, with a western extension into Saurashtra (breeding in Jamnagar) and Kutch. Eastward along the lower Himalayas up to c. 700 m from Jammu and S. Kashmir to Gonda and Mirzapur districts, U.P.; Bihar (?), and southward through

SWALLOWS

65

the Peninsula to c. 11°N. (Coimbatore). Not recorded east of c. 84°E. — in Bengal, Assam or E. Pakistan. Stuart Baker's 'east to Sikkim' is shown to be erroneous (Whistler, JBNHS 36: 841), while its breeding in Baluchistan (Williams, *ibid.* 33: 606) is incredible and probably due to mistaken identity. Confirmation desirable. One sight record in Ceylon (Phillips, JBNHS 47: 740). Affects open country and cultivation in the vicinity of water — rivers, canals, moats, reservoirs, etc.

Extralimital. Eastern Afghanistan.

GENERAL HABITS. Highly gregarious. Usually keeps in large flocks, hawking midges etc. in close proximity of water along with other swallows. On wintry mornings often seen sitting in densely packed rows on telegraph wires near or over water till the sun is well up. At one point the congregation suddenly 'explodes' as to a given signal, and the birds disperse to feed in small groups. Flight comparatively feeble and wandering, with fewer glides and swoops than in Western Swallow.

FOOD. Midges, gnats and other dipterous insects.

VOICE AND CALLS. A sharp *trr, trr* uttered in flight. A twittering chirp in uneven chorus while clinging outside nest and shivering wings. Song, if any, not described.

BREEDING. *Season*, in cold-winter northern districts chiefly March to June; elsewhere practically all year with peak periods December to April and July to October. Often two (or three?) successive broods. *Nest*, colonial — a large agglomeration of mud, reminiscent of an untidy honeycomb or a cluster of potter wasp nests — sometimes of a hundred or more 'pots' fused together, each with a short narrow outwardly projecting entrance-tube, 5 to 12 cm long. Egg-chamber cosily lined with grass and feathers. The whole mass attached under masonry bridges spanning rivers, canals, and moats of ancient forts, under gateway arches of archaeological monuments and the like, usually above or close to water, often within populous towns. The same colony, with the nests repaired and some replaced, is occupied year after year, the site becoming traditional if left unmolested.

Breeding biology needs detailed study. Superficial observation suggests polygyny or promiscuity, many seemingly promiscuous copulations taking place on the ground while a party is collecting mud at a rain puddle. Two cases reported of a large proportion of fledged young in a colony being unaccountably found dead within the nests, in every case with the desiccated remains protruding from the narrow entrance-hole (Begbie, JBNHS 16: 512; Young, *ibid.* 16: 753).

Parties of some 20 or 30 birds fly out together to collect wet mud pellets, and back to the colony. The traffic continues all day, especially morning and afternoon. The returning birds mill around the nests in a jumble, entering and leaving the spouts; how each recognizes its own nest is a puzzle. *Eggs*, generally 3, occasionally 4, white, sometimes smudged with yellowish brown or pale sepia spots. Average size of 125 eggs 18.5 × 13.1 mm (Baker). Both sexes share in building the nest and feeding the young; apparently also in incubation. Period undetermined.

MUSEUM DIAGNOSIS. See Key to the Species.

Young (immature). Head brownish; feathers of mantle margined with rufous; of rump and wings with fulvous.

d Striations on lower plumage hardly broader than the shafts	70
B Rump paler posteriorly and becoming creamy white on the upper tail-coverts	67
II Lower plumage chestnut	72

923. Daurian Striated or Redrumped Swallow. *Hirundo daurica daurica* Linnaeus

Hirundo daurica Linnaeus, 1771, Mantissa Plant.: 528 (Siberia)

Lillia substriolata Hume, 1877, Stray Feathers 5: 268 (Cachar)

Baker, FBI No. 1159, Vol. 3: 248

LOCAL NAME. *Midli* (Khasia).

SIZE. Sparrow ±; overall length c. 20–23 cm (7½ in.) depending on length of tail.

FIELD CHARACTERS. As of 927, q.v. See Key to the Subspecies and Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Apparently rare winter visitor to the Himalayas, in Nepal, Sikkim (?), Bhutan, and NEFA.

Extralimital. Southern Siberia, eastward through the Baikal region, northern Mongolia and Transbaikalia; central western China. (For details see Vaurie, 1959, 2: 14.) Winters also in the Indochinese countries.

GENERAL HABITS, FOOD, VOICE and CALLS. As in Indian Striated Swallow (927), and other races.

68

HIRUNDINIDAE

FIELD CHARACTERS. As of 927, q.v., but rump much paler, almost whitish. See Key to the Subspecies and Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident and/or summer visitor (March to September/October). Northern Baluchistan, Punjab (NW. frontier districts), Gilgit, Chitral, Kashmir, Himachal Pradesh; between c. 1000 and 3300 m. Affects open but broken hilly country, near and away from human habitations.

Extralimital. Breeds in parts of southern Europe and eastward through western Asia (Middle-East countries) to Afghanistan and Russian Turkestan. (For details see Vaurie, 1959, 2: 12.)

GENERAL HABITS, FOOD, VOICE and CALLS. As in 927.

BREEDING recorded in N. Baluchistan (Quetta and Fort Sandeman districts), Punjab (Fort Munro), Chitral, Kashmir and Himachal Pradesh. *Season*, chiefly April to July. *Nest*, eggs (c/3 or 4) and breeding biology as in Indian Striated Swallow (927).

MUSEUM DIAGNOSIS. * Underparts varying from buffy to whitish with very narrow, faint or obsolete dark shaft-streaks* (Vaurie). Differs from *erythrogygia* (927) in having finer striations on underparts, and chestnut on rump paling off to creamy white posteriorly.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail	
				central	outer
♂ ♀	112–126	9–10	12–14	39–47	85–102 mm (HW)

Weight 4 ♂ ♂ 14–17 g (Paludan, Afghanistan).

COLOURS OF BARE PARTS. As in 927 and other races.

925. Himalayan Striated or Redrumped Swallow. *Hirundo daurica nipalensis* Hodgson

Hirundo Nipalensis Hodgson, 1836, Jour. Asiat. Soc. Bengal 5: 780 (Nepal)

Baker, FBI No. 1161, Vol. 3: 250

LOCAL NAMES. As for 927; *Phairi* (Kashmir).

SIZE. Sparrow ±; length c. 19 cm (7½ in.) including long tail.

FIELD CHARACTERS. As in 927, q.v. but with paler chestnut rump. See Key to the Subspecies and Museum Diagnosis.

Large gatherings huddled on telegraph wires in winter.

SWALLOWS

69

STATUS, DISTRIBUTION AND HABITAT. Breeds in the Himalayas from Kulu in Himachal Pradesh eastward through Garhwal, Kumaon, Nepal, Sikkim, Bhutan and NEFA; between c. 1200 and 3200 m in the western Himalayas, in a lower zone in the eastern. Winters (October/November to February/March) more or less throughout the Peninsula from Uttar Pradesh southward to Kerala, and from Gujarat and Rajasthan eastward to Orissa. In winter several subspecies are found side by side in the Indian plains, impossible to differentiate in the field with certainty: hence their movements and non-breeding ranges remain unclear. Affects cultivation, forest clearings and lightly scrubbed open country in winter; in summer (when nesting) grassy slopes and rocky hills around upland pastures and scattered homesteads, as well as populous hill villages and hill-stations.

Extralimital. Extends eastward to southwestern Sikang. Winters also in Burma.

GENERAL HABITS. Very gregarious in winter; scattered pairs or family parties in summer. Great influx of Himalayan migrants in the north and central Indian plains and Deccan from about November. Enormous congregations (swarms) commonly met with on winter mornings perched in close-packed rows of hundreds, or thousands, on telegraph wires often occupying several adjacent strands of wire over stretches of 200 metres or more, sometimes even overflowing on to neighbouring trees or the ground. Frequently the swarms settle sprawled out on damp, sandy river beds and shoals, or in newly ploughed fields. From time to time the birds launch out spontaneously to fly around in a dense rabble and gradually re-settle. The gathering disperses to hawk insects as the sun gets warmer. The sunning congregation becomes smaller day by day, gradually splitting up into smaller parties and moving on or scattering over the countryside for the season. The birds roost at night in partly submerged reed-beds and the like.

FOOD, VOICE AND CALLS. As in 927.

BREEDING. Season, overall April to August chiefly May to July. Nest, eggs (c/3 or 4, rarely 5), and breeding biology as in Indian erythropygia (927). Two broods often raised in succession in same nest; sometimes three. Nest stuck against ceiling in a veranda or living-room of occupied or derelict hill-station bungalows, busy bazaar shops, under masonry culverts or rock overhangs and in tunnels and the like; nests usually individual; sometimes two or three in the same structure, but well apart — not colonially. The same site and nest, repaired if necessary, may be used year after year.

MUSEUM DIAGNOSIS. Streaks on underparts coarser than in erythropygia, especially in winter. Rump paler chestnut (seasonally variable but never so dark as in erythropygia) and distinctly dark shaft-streaked. Differs from rufula in having more heavily streaked underparts and darker chestnut rump.

Young (immature) has no, or only obsolete, striations on breast.

MEASUREMENTS

7 ♀♀	109-120	10-11	—	—	82-95 mm (BB)

SWALLOWS

71

eastward from Punjab, Rajasthan and northern Gujarat (including Kutch and Saurashtra) to West Bengal. Plains and peninsular hills up to c. 1600 m. Not in Sind, Assam or East Pakistan. Rare straggler to Ceylon in winter. Affects open cultivated country and clearings in light deciduous forest, preferably the neighbourhood of archaeological ruins — old forts, mosques, temples, etc. — and rocky hills.

GENERAL HABITS. Much less gregarious than the migratory races, e.g. nipalensis. Keeps in pairs, family parties or small flocks hawking insects all day in company with swifts, crag martins and other swallows, alighting to rest from time to time on ledges, telegraph wires or tree-tops. Is less closely attached to the neighbourhood of water — reservoirs, streams, canals, etc. — than Wiretailed Swallow, and commonly met with hawking over drier country. Flight slower and more deliberate than that of Wiretailed, with fewer swoops. Numbers gather to hawk insects fleeing from fired grassfields and forest clearings, in mixed company with other birds. Threshing and winnowing floors and open-air grain markets, bazaars, railway goods yards and shipping docks where insects abound are also favourite hunting grounds.

FOOD. Gnats, midges and tiny flying beetles and bugs — Diptera, Coleoptera and Hemiptera. Winged ants and termites etc.

VOICE AND CALLS. Flight note, 'a loud low-pitched cheer, a sparrow-like chirp, and a more nasal queenk' (Nichols); more plaintive, and distinct from rustica's. Song, in breeding season, a cheerful subdued twittering, often uttered by the male while the pair is sitting side by side, and also near the nest (SA).

BREEDING. Season, overall April to August, the principal periods varying locally. Nest, typically retort-shaped, of conglomerated mud pellets — a bulbous hemisphere c. 15 cm in outside diameter, with a prolonged horizontal entrance-tunnel c. 15-18 cm, of c. 4 cm bore. The whole is stuck flat against the ceiling of a deserted or occupied dwelling, under the dome of ancient mosques or tombs, under masonry arches of bridges over canals, under natural rock overhangs and suchlike situations. In the developing India of today reinforced concrete road culverts are increasingly favoured. Egg-chamber copiously lined with grass, feathers and vegetable down. Eggs, 3 or 4, rarely 5, pure white. Average size of 60 eggs 21.0 × 14.4 mm (Baker). Often two or three successive broods raised in the same nest. Same site and nest, repaired or rebuilt as necessary, may be used year after year. Both birds share in nest construction, collecting mud blobs at nearby rain puddles, shuttling back and forth more or less together. Nest takes several days to complete as one mud layer must set before the next is put on; the whole dries to terracotta hardness. Both sexes incubate by turns, and both birds roost within at night even when incubation in progress. Family parties keep together by day and roost within nest at night until young become fully independent. While one bird is incubating the other will often continue to add fresh mud to the rim of the entrance-tunnel. Its diameter evidently constricts on drying, sometimes with fatal results to the inmates. Two cases recorded of birds getting stuck in the exit while trying to leave nest, and dying in that position (Davison, SF 10: 345; Himmatsinhji, JBNHS 56: 631) cf. also Cliff Swallow, p. 65. Incubation period undetermined. Nest built singly, not in colonies; frequently close to 'nest villages' of House Swifts. Often usurped by the latter and by House Sparrows.

70

HIRUNDINIDAE

Weight 2 ♀♀ 16, 18 g (GD).

COLOURS OF BARE PARTS. As in 927.

926. Japanese Striated or Redrumped Swallow. *Hirundo daurica japonica* Temminck & Schlegel

Hirundo alpestris japonica Temminck & Schlegel, 1847, in Siebold's Fauna Jap., Aves, Pl. 11: 33 (Japan)

Not in Baker, FBI cf. *H. d. daurica*, Vol. 3: 248

LOCAL NAMES. None recorded.

SIZE. Sparrow ±; length c. 19 cm (7½ in.) including long tail.

FIELD CHARACTERS. As in 927, q.v. See Key to the Subspecies and Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. A winter migrant to Uttar Pradesh, Madhya Pradesh, Gujarat (Saurashtra), Mysore (Londa), Tamil Nadu, Andhra, W. Bengal, Assam and presumably East Pakistan. A doubtful specimen from Andaman Is. (Port Blair); another taken recently in central Nepal, January (Fleming, JBNHS 65: 330). Owing to overlapping of several races in the winter quarters, their movements and non-breeding ranges unclear.

Extralimital. Breeds in Manchuria, Korea, Japan, NE. and E. China; winters also in N. Thailand and Burma. (For details see Vaurie, 1959, 2: 13.)

GENERAL HABITS, FOOD, VOICE AND CALLS. Presumably as in 927.

BREEDING. Extralimital.

MUSEUM DIAGNOSIS. Distinctly more heavily streaked below than nominate *daurica* and with faint streaks on rump which are usually absent or fainter in nominate *daurica*; somewhat smaller. Wing ♂♂ 114-125; tail 85-106 mm (Vaurie, 1959, 2: 13).

COLOURS OF BARE PARTS. As in 927 and other races.

927. Indian Striated or Redrumped Swallow.

Hirundo daurica erythropygia Sykes

Hirundo erythropygia Sykes, 1832, Proc. Zool. Soc. London: 83 (Dukhun, Poona) Baker, FBI No. 1162, Vol. 3: 251

Plate 108, fig. 1

LOCAL NAMES. *Māsūd ābābil* (Hindi); *Vāṛāṇkātrikā* (Malayalam); *Kēncī ābābil* (Gujarati).

SIZE. Sparrow ±; length c. 19 cm (7½ in.) including long tail.

FIELD CHARACTERS. A deeply fork-tailed swallow. Above, glistening steel blue-black; a narrow supercilium and sides of head chestnut connected by a chestnut half-collar on hindneck; rump chestnut, conspicuous and diagnostic in banking flight. Below, fulvous white, finely streaked with dark brown. Terminal half or one-third of under tail-coverts abruptly black. Sexes alike. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident; largely sedentary with slight seasonal local movements. More or less throughout the subcontinent, from c. 1200 m in the outer Himalayan foothills and terai south to Kerala, and

72

HIRUNDINIDAE

MUSEUM DIAGNOSIS. Size small. Rump uniform dark chestnut without blackish shaft-streaks. Striations on underparts narrow. Tail-fork comparatively shallow. An indistinct white patch on inner web of outermost rectrices. Shape and proportions of adult tail similar to that of juvenile in other races.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail central	outer
♂ ♀	104-116	9-10	13-15	39-46	70-82 mm (SA, HW)

Weight 7 ♂♂ 15-19 (av. 16.7) g — SA.

In the flesh tarsi conspicuously stouter than in *H. rustica*.

COLOURS OF BARE PARTS. Iris brown. Bill brownish black; mouth pale yellowish grey. Legs, feet and claws brownish black.

928. Ceylon Striated or Redrumped Swallow.

Hirundo daurica hypertythra Blyth

Hirundo hypertythra Blyth, 1849, Jour. Asiat. Soc. Bengal 18: B14 (Ceylon, ex Layard MS.)

Baker, FBI No. 1164, Vol. 3: 253

Plate 65, fig. 15

LOCAL NAMES. *Wēhi līhīniyā* (Sinhala); *Tām pādi*, *Tādi illāda kūṛuvī* (Tamil).

SIZE. Sparrow ±; length c. 19 cm (7½ in.) including long tail.

FIELD CHARACTERS. As in 927, q.v., but underparts deep chestnut, faintly and narrowly striated. Nuchal collar absent or ill-defined; rump much darker chestnut. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Race peculiar to Ceylon. Plentiful throughout the low country (except perhaps the Jaffna Peninsula and neighbouring islands) and hills to c. 1200 m. Affects open grassy country, paddy-fields and grass-covered hillsides.

GENERAL HABITS AND FOOD. As in 927.

VOICE AND CALLS. Loud, musical, distinctive, 'easily recognized when once heard' (Henry).

BREEDING. Season, chiefly March to July, but occasionally in September and from November to January (Phillips). Nest and eggs (c/2 or 3) as in 927. Average size of 7 eggs 21.3 × 14.3 mm (Baker).

MUSEUM DIAGNOSIS. See Field Characters (above) and Key to the Subspecies

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	102-122	c. 7	c. 12-13	75-78 mm (Baker)

Weight 2 ♂♂ 14, 16 g (SDR).

COLOURS OF BARE PARTS. Iris sepia brown. Bill blackish brown. Legs and feet vinous brown (Wait).

SWALLOWS

73

929. Chinese Striated or Redrumped Swallow. *Hirundo striolata* mayri Hall*Hirundo striolata* mayri Hall, 1953, Ibis 95: 547

(Singhaling, Hkamti, Upper Chindwin, Burma)

LOCAL NAME. *Inra gobi* (Kacha Naga).SIZE. Sparrow \pm ; length c. 19 cm (7½ in.) including long tail.

FIELD CHARACTERS. As in 927, q.v. See Key to the Species.

STATUS, DISTRIBUTION and HABITAT. Partly resident, partly winter visitor. Assam hills south of Brahmaputra R. (Khasi, N. Cachar, etc.) and in the Margherita area (Lakhimpur dist.), Nagaland, Manipur, and the hills of East Pakistan(?).

EXTRALIMITAL. Burma, Thailand, and Indochinese countries.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 927.

BREEDING. Season, in Assam (c. 1000-1400 m) April and May. Nest and eggs (c/3 to 5 generally 4) pure white as in races of *daurica*. 'Exceptionally an egg may be found with a few faint reddish specks on the larger end.' Average size of 30 Assam eggs 21.4 × 14.7 mm (Baker).MUSEUM DIAGNOSIS. Rufous collar on hindneck absent or broadly interrupted. Much more heavily and coarsely streaked on underparts than *H. d. nipalensis*; rump-band narrower, darker chestnut, with the shaft-streaks sometimes ill-defined.

MEASUREMENTS

9 ♂♀ Wing 120-124; tail 83-97 mm (Mayr, SDR)

Weight 1 ♀ 22 g (SDR).

COLOURS OF BARE PARTS. As in 927 and other races of *daurica*.

Genus DELICHON Horsfield & Moore

Delichon Horsfield & Moore, 1854, Cat. Bds. Mus. E.I. Co. 1: 384. Type, by monotypy, *Delichon nipalensis* Moore

Distinguished from all other swallows by wholly feathered or 'stockinged' tarsi and toes. Rump conspicuously white. Tail varying from deeply forked to almost square.

Key to the Species

Weight 1 ♂ 17 g (Paludan).

COLOURS OF BARE PARTS. Iris brown. Bill black (adult) or horn brown (immature). Legs and feet pinkish yellow, covered with white feathers.

931. Kashmir House Martin. *Delichon urbica cashmeriensis* (Gould)*Chelidon Cashmeriensis* Gould, 1858, Proc. Zool. Soc. London: 356 (Kashmir)

Baker, FBI No. 1142, Vol. 3: 228

Plate 65, fig. 10

LOCAL NAMES. None recorded.

SIZE. Sparrow; length c. 15 cm (6 in.).

FIELD CHARACTERS. As in 930, q.v., but with the rump and underparts sullied with smoky grey, not glistening white. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Resident, and partly local migrant. Breeds in the Himalayas between c. 1500 and 5000 m altitude. Chitral, Gilgit, Kashmir, Himachal Pradesh and eastward through Nepal, Sikkim, Bhutan and NEFA. Sight records often confused with *D. u. urbica*. Winter range imperfectly known but occurs in the foothills, terai and duars, and in the northern plains from Ambala east through Kumaon, U.P., Bihar to Assam and East Pakistan (?). Affects open valleys, grassy hillsides with cliffs, and the environs of mountain villages.

EXTRALIMITAL. SE. Afghanistan, SE. Tibet, eastward to Kansu (for particulars see Vaurie, 1959, 2: 16-17). Recorded in winter from N. Thailand and N. Burma.

GENERAL HABITS. Typical swallow, cf. 927. Highly gregarious while nesting as well as at other times. Loose parties commonly seen hawking midges and tiny winged insects in company with Striated and other swallows and house swifts high above gorges and stream valleys, terraced fields, or above the rising smoke of forest fires. In Kashmir canals and waterways are favourite hunting resorts. Flight swift and graceful — a few rapid wing-beats followed by effortless glides and swoops, and agile twisting, turning and banking movements.

FOOD. Insects, chiefly Diptera, taken on the wing.

HIRUNDINIDAE

74

930. European House Martin. *Delichon urbica urbica* (Linnaeus)*Hirundo urbica* Linnaeus, 1758, Syst. Nat., ed. 10, 1: 192 (in Europe = Sweden) Baker, FBI No. 1141, Vol. 3: 226

LOCAL NAMES. None recorded.

SIZE. Sparrow; length c. 15 cm (6 in.).

FIELD CHARACTERS. A small black and white swallow with short forked tail. Above, glossy blue-black with glistening white rump; below, pure white including feathered legs and feet. Sexes alike.

Tail, 'stockinged' foot, head and bill. × c. 1

In flight its diagnostic points are: white rump as in House Swift; white underparts as in Wiretailed Swallow; short slightly forked tail as in Cliff Swallow.

STATUS, DISTRIBUTION and HABITAT. Status unclear owing to difficulty of distinguishing in the field from Kashmir Martin (931). Apparently breeds at high altitudes in Ladakh and N. Kashmir (Shyok, Nubra and Indus valleys) also in the valleys of the Dras, Suru, Zaskar and other rivers of that region between c. 3000 and 4500 m. Sporadic in winter, and/or on migration, in the NW. frontier districts of W. Pakistan and N. Baluchistan, Nepal foothills (specimen, April, Fleming, JBNHS 65: 330), and in peninsular India mostly down the western side. Recorded from Gujarat, Saurashtra, Maharashtra, Madhya Pradesh, Mysore, Nilgiri Hills and Kerala — as late as end April and mid May. For particulars of occurrences in the Peninsula see Editors, JBNHS 65: 222. Has also occurred in the Laccadive and Maldives Is. (Mathew & Ambedkar, JBNHS 61: 189; Phillips & Sims, ibid. 56: 214). Affects open valleys and grassy hillsides with cliffs.

EXTRALIMITAL. Russian Turkestan, Afghanistan, Iran, Transcaucasia, Asia Minor; the Mediterranean countries and nearly all Europe (including Great Britain) north to Scandinavia. For particulars see Vaurie, 1959, 2: 15.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 931.

BREEDING. Season, in Ladakh, June and July. Nest and eggs, as in Kashmir House Martin (931).

There is considerable confusion in published (sight) records, and both *urbica* and *cashmeriensis* are reported breeding in the same localities, often

HIRUNDINIDAE

76

VOICE and CALLS. Not intelligibly described: only as 'squeaks and twittering'.

BREEDING. Season, chiefly end May to mid July. Nest, a deep earthen cup, or rounded 'pot', of agglomerated mud pellets attached under a rock-ledge or overhang on a high cliff-face, leaving a narrow slit between ceiling and nest-top for the bird to squeeze in. Sometimes nest-top actually connected to ceiling, in which case a small lateral entrance-hole left at top. Architecture of nest varies according to site and contours of substrate. Nests built solitarily or in small scattered groups — 10 to 12 (or more) — not in clusters like House Swifts; lined with grass and feathers. In high mountain villages sometimes builds under eaves or window corners of wooden houses, the nests looking singularly like enlarged nests of potter wasps (*Eumenes*). Eggs, 3 or 4, white, unmarked. Average size of 80 eggs 17.9 × 12.7 mm (Baker). Incubation period undetermined. Often two broods raised. Both sexes take part in nest-building, incubation and feeding the young. Food brought assiduously every few minutes, the birds fluttering at nest momentarily without alighting, hurriedly transferring the morsels to the widely gaping bills crowding the entrance, and flying off to fetch more. Young apparently fend for themselves on leaving nest though returning to roost in it with parents the first few nights. Not observed being fed in mid-air like other swallows.MUSEUM DIAGNOSIS. See Field Characters. Differs from *D. u. urbica* (930) further in having the ear-coverts mostly dark brown (v. white); axillaries and underwing dark brown; fork in tail shallower.

Young (immature). Above, rump white, sometimes with a pale vinous wash; rest of upperparts, including wings and tail, dark brown with slight gloss on mantle and scapulars. Below, as in adult, or washed with pale vinous.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♀	99-105	8-10	9-11	38-43 mm (CBT, HW)

Weight 1 ♂ 14.7 g (GD); 1 o? 15 g (SA).

COLOURS OF BARE PARTS. As in 930.

932. Nepal House Martin. *Delichon nipalensis nipalensis* Moore*Delichon nipalensis* 'Hodgson' = Moore in Horsfield & Moore, 1854, Cat. Bds. Mus. E.I. Co. 1: 384 (Nepal)*Delichon nipalensis bartlettii* Koelz, 1952 (Sept.), Jour. Zool. Soc. India 4: 43 (Himuntha, Lushai Hills)*Hirundo cuttingi ernstmayri* Walters, 1953 [Feb.], (1952), Bonner Zool. Beitr. 3: 280 (New name for *D. nipalensis* Moore if placed in genus *Hirundo*, preoccupied) Baker, FBI No. 1144, Vol. 3: 230

Plate 65, fig. 7

LOCAL NAMES. *Biri dzo* (Cachar); *Inra bi* (Naga).SIZE. Sparrow \pm ; length c. 13 cm (5 in.).

FIELD CHARACTERS. A small black and white swallow with a short square-cut tail. Above, steely blue-black including ear-coverts, wings and tail. Rump

SWALLOWS

77

glistening white. A broken white collar on hindneck. *Below*, chin and throat dull black; under tail-coverts glossy black. Rest of underparts pure white including 'stockinged' legs and feet. Sexes alike.

Could casually be confused with *D. urtica*, but on a good view, black throat and under tail-coverts, and square-ended tail (v. forked) diagnostic.

STATUS, DISTRIBUTION and HABITAT. Resident, with some local (mostly altitudinal) movements. The Himalayas from Garhwal and Kumaon through Nepal, Sikkim, Bhutan and NEFA; Assam hills south of Brahmaputra R., Nagaland, Manipur, Mizo; East Pakistan hills (?). Breeding between c. 2000 and 4000 m; down to c. 350 m in winter. Affects river valleys, mountain ridges with vertical cliffs, etc.

Extralimital. N. Burma and N. Vietnam.

GENERAL HABITS. Highly gregarious; very similar to those of the Kashmir House Martin (931), q.v. Subject to sudden sporadic appearances and disappearances in winter. The birds fly round continuously in a scattered rabble hawking insects high up in the air or skimming the tree-tops and bushes. From time to time one will suddenly climb almost vertically for 10 metres or so (to take a midge?) and then dive and flatten out when quite close to the bush or ground again. The fast smooth-flowing flight with its swoops, glides and 'tight' turns has been likened to skating.

FOOD. Tiny winged insects, mostly Diptera.

VOICE and CALLS. On the whole very silent. Occasionally utters a short high-pitched *chi-i* in flight (Lister).

BREEDING. *Season*, overall April to July, the peak periods varying locally and with altitude. *Nest*, as in Kashmir House Martin, a deep earthen bowl or 'pot', lined with fine grass and feathers, attached under a rock overhang on a vertical cliff-face, with a narrow slit or hole near top for entrance. Not recorded nesting in houses. Nests colonial, often 25 to 50 or so under the same overhang close together, sometimes almost touching one another, but not agglomerated in a mass or 'village' like House Swifts. *Eggs*, 3 or 4, rarely 5, white, unmarked, very like those of 931. Average size of 21 eggs 18.6 × 12.8 mm (Baker). Both sexes share in building the nest, incubation, and feeding the young. Incubation period undetermined.

MUSEUM DIAGNOSIS. See Field Characters.

Young (immature). Like adult but black of upperparts less glossy, and white of underparts sullied with buff.

MEASUREMENTS	Wing	Bill (from skull)	Tarsus	Tail (SA)
♂ ♀	90-98	7-9	11-12	37-41 mm

Weight 1 ♂ 14, 1 ♀ 16 g (SA).

COLOURS OF BARE PARTS. Iris brown. Bill black. Legs and feet (through white stockings) pale brownish flesh; claws horny brown.

A significant difference in the pattern of moult and plumage renewal between this species and *D. u. cashmeriensis*, closely correlated with their ecological peculiarities, has recently been described. See Stresemann, E., & V., 1969, 'Die Mauser von *Ptyonoprogne rupestris* and *Delichon nipalensis*'. *Jour. Orn.* 110 (1): 39-52.

Plate 66, fig. 12

LOCAL NAMES. *Dūdiya lātorā*, *Sāfēd lātorā*, *Bādā lātorā* (Hindi); *Dūdhiō* or *Mōto lātorā* (Gujarati); *Kachka*, *Anjānā* (Bengal); *Peddā kiriti gādu* (Telugu).

SIZE. Myna ±; overall length c. 25 cm (9½ in.) including long tail.

FIELD CHARACTERS. A 'bull-headed' silvery grey bird with longish graduated black-and-white tail. Wings black with a pure white patch or 'mirror' which flashes conspicuously in flight. A broad black band from forehead and bill backward across eye to ear-coverts. Heavy hooked bill like a bird of prey's. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Resident; local movements (winter dispersal) not worked out. Breeds in Baluchistan (Las Bela to Nal in south Kalat, Sibi plain), Sind, NW. frontier districts, Punjab, Rajasthan, Gujarat (including Kutch and Saurashtra) and through the Bombay Deccan south to Mysore (Belgaum); east through Madhya Pradesh, Maharashtra (to c. Nagpur), and Andhra (north of Kistna R.) to Bihar and southern W. Bengal; E. Pakistan (nr. Kushtia, c. 23°54'N., 89°07'E. — H. Rashid, 1967); from plains level to c. 1200 m. Two records from Tamil Nadu (Cuddapah dist.); one unconfirmed sight record from Ceylon (Phillips). Affects open semi-desert country, sparse scrub jungle, edges of desert cultivation, and thorn- and dry-deciduous forest.

78

LANIIDAE

Family LANIIDAE: Shrikes or 'Butcher Birds'

For morphological characters and description see Van Tyne, J. & Berger, A. J., 1959: 534; Baker, E. C. Stuart, 1924, FBI 2: 283-4; Olivier, G. G., 1964, Article 'Shrike' in Thomson, A. L. (ed.), *New Dict. Birds*. London and New York.

Grey Shrike (933)

Genus LANIUS Linnaeus

Lanius Linnaeus, 1758, Syst. Nat., ed. 10, 1: 93. Type, by subsequent designation.

Lanius excubitor Linnaeus

Cf. Olivier, G., 1944, Monogr. des Pies-Grièches du genre *Lanius*, Rouen: 1-324 Bill very stout and laterally compressed, the upper mandible downcurved and hooked, and with a large tooth and a deep notch near the tip; Nostils nearly round, almost hidden by numerous bristles. Plumage firm but not spinous. Wings pointed. Tail equal to or longer than wing, strongly graduated.

80

LANIIDAE

GENERAL HABITS. Bold and aggressive. Keeps singly or in widely separated pairs, perched upright on an exposed thorn bush or telegraph wire surveying the surroundings. Pounces from time to time on crawling prey which is either carried back in bill to the perch or disposed of on the ground, held underfoot and torn to pieces before being devoured by vicious jabs and upward tugs of the sharp hooked beak. Each individual has a staked-out feeding territory, frequented day after day and jealously guarded against interlopers. Has the well-known habit, shared by many of its congeners, of maintaining a 'larder' where surplus food (locusts, lizards, young mice, young birds, etc.) is impaled on thorns etc. to be eaten at leisure (hence the English name 'butcher bird'). Everywhere excessively wary and usually difficult to approach: this evidently an inherent trait and not the result of persecution. In common with other shrikes has the shikra-like trick of dropping from its perch when alarmed or suspicious and flying off at high speed flat along the ground on rapidly 'vibrating' wings, swooping steeply upwards to settle on another exposed bush-top a hundred metres or so away.

FOOD. Entirely carnivorous. Insects — locusts (adults and hoppers), *Chrotogonus* spp., black ants (e.g. *Myrmecocystus laevis*) and other Hymenoptera, *Agrotis* caterpillars, beetles, bugs, etc. (Hussain & Bhalla, JBNHS 39: 834). Also lizards, young rodents (mice, squirrels, etc.), and young or sickly birds (full-grown lark and young Brahminy Myna recorded); known to attack a wounded sandgrouse and drill a hole through back of its skull (O'Brien, JBNHS 26: 667).

VOICE and CALLS. Common call 'a harsh kwi-riick, kwi-riick' (Dharma-kumarsinhji). Notes of concern a grating *che-che* uttered by parent from near by when its nest being examined. In breeding season male has a short lively tinkling song, rather like Grey Tit's, but more musical. Like other shrikes, is an accomplished mimic of other birds' calls.

BREEDING. *Season*, overall January to October, mainly March to June. *Nest*, a deep compact cup of thorny twigs and grass intermixed with rag, hair, lumps of cotton, feathers, wool, etc. with the rags and rubbish hanging untidily from the structure. Size between c. 13 and 18 cm across externally, with the cup c. 8 to 10 cm in diameter and c. 6-7 cm deep. Placed in a babool or *Prosopis* tree or in a thorn bush, 2 to 4 metres up; commonly in the same locality and in more or less the same site year after year (sometimes the old nest renovated) unless disturbed. Old nests of crows and babblers often appropriated and adapted. *Eggs*, 3 to 6, considerably variable in colour and size. Commonest type pale greenish white thickly blotched and spotted with purplish brown, especially at the broad end. Some eggs very reminiscent of House Crow's. For range of variations see Baker, *Nidification* 2: 254-5. Average size of 100 eggs 25.9 × 19.7 mm (Baker). Both sexes take part in nest-building, incubation and feeding the young. Incubation period undetermined.

MUSEUM DIAGNOSIS. See keys to the Species and Subspecies. Underparts pure white. Bill heavier and tail longer than in *pallidirostris* (934). Black frontal band 4-5 mm wide; narrower in first-winter plumage.

Young (immature). *Above*, grey clouded with brown, with obsolete dark bars; *underparts* and all wing-coverts tipped fulvous. *Below*, white tinged with fulvous. Post-juvénal moult includes body, all coverts except primary, and the tertials. First-winter plumage distinguished by pale tips to primary-coverts.

SHRIKES

81

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	108-115	20-26	30-33	106-122 mm
♀♀	105-113	19-25	29-32	107-118 mm (SA)

Weight 1 ♂ 52; 3 ♀♀ 55-66 g (BB).

COLOURS OF BARE PARTS. Iris dark brown. Bill horny black; mouth pale pink or greyish pink. Legs, feet and claws blackish brown.

MISCELLANEOUS. Young birds easily reared in captivity, becoming quite tame, flying freely and coming at call. In Mogul times was trained, along with falconets (*Microhierax*) to hunt sparrows and even larger birds.

934. Baluchistan Grey Shrike. *Lanius excubitor pallidirostris* Cassin

Lanius pallidirostris Cassin, 1852, Proc. Acad. Sci. Philadelphia 5: 244
(East Africa = Eritrea vide Meinertzhagen, 1954, Bds. Arabia: 164)
Baker, FBI No. 707, Vol. 2: 287

LOCAL NAMES. None recorded.

SIZE. Myna ±; overall length c. 25 cm (9½ in.) including long tail.

FIELD CHARACTERS. As in 933, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Summer (breeding) visitor — March to October/November — to northern Baluchistan from Kalat to Fort Sandeman between c. 1500 and 2100 metres. Resident and breeding (?) in coastal Makran. Straggles in winter to the Sibi plain, Sind, Punjab and Rajasthan: probably often overlooked among the commoner *lahtora*. Affects open semi-desert country.

Extralimital. The desert and semi-desert parts of the Astrakhan region east to Zaisan Nor, Dzungaria, S. Mongolia, southward to the Aral-Caspian region, Russian Turkestan, Transcaspia, NE. Iran, etc. In winter to Iraq and NE. Africa. For particulars see Vaurie, 1959, 2: 114.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 933.

BREEDING. Breeds in the valleys on the lower parts of the higher hills in N. Baluchistan. Season, nest, eggs and breeding biology as in *lahtora* (933).

MUSEUM DIAGNOSIS. Differs from *exuber* (935) and *lahtora* (933) in lacking, or almost lacking, the black frontal band; lores more dusky, not so pure black; no grey on under wing-coverts; underparts usually with a faint pinkish wash. Bill horn colour r. black.

MEASUREMENTS

	Wing	Tail
♂♀	105-112 (rarely up to 117)	104-116 mm (Hartert)

Outermost rectrices 25-30 mm shorter than central pair.

Females usually smaller than males.

COLOURS OF BARE PARTS. Iris brown. Bill horn colour (except in a very few adults). Legs, feet and claws blackish brown.

SHRIKES

83

Extralimital. From Bulgaria, Rumania and SE. Russia eastward across W. Siberia to the Yenisey Valley. For particulars see Vaurie, 1959, 2: 109.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 933 and other subspecies.

BREEDING. Extralimital.

MUSEUM DIAGNOSIS. Differs from other subspecies in having the frontal band whitish. Grey of upperparts paler than in *lahtora* (about the same as in *pallidirostris*); rump and upper tail-coverts whitish; lesser wing-coverts grey; basal part (c. 25 mm) of tail-feathers white; black of flight-feathers confined to c. 25 mm on subterminal part of secondaries and to c. 40 mm of primaries.

MEASUREMENTS

10 ♂♂ Wing 113-119 (av. 115) mm — Vaurie
COLOURS OF BARE PARTS. As in 933.

937. Lesser Grey Shrike. *Lanius minor* Gmelin

Lanius minor Gmelin, 1788, Syst. Nat. 1: 308 (Italy)
Not in Baker, FBI
Plate 66, fig. 11

LOCAL NAMES. None recorded.

SIZE. Myna ±; length c. 23 cm (9 in.) including tail.

FIELD CHARACTERS. A slightly smaller edition of the Grey Shrike in general effect, but with the forehead black contra grey with a narrow black frontal band.

STATUS, DISTRIBUTION AND HABITAT. Status? Has been obtained on passage (?) in N. Baluchistan (near Quetta in May, and at Chaman in April); there is a specimen from Kandahar in the British Museum (14.iv.1881). May occur in the NW. frontier districts of West Pakistan. Affects open semi-desert and cultivation with scattered thorn bushes.

Extralimital. Afghanistan, Iran, Asia Minor, S. Europe, etc. For particulars see Vaurie, 1959, 2: 106-7.

BREEDING. Extralimital.

MUSEUM DIAGNOSIS. Upper breast and flanks tinged with rose-pink; rest of underparts white. Differs from *exuber* also in wing formula: 1st primary (as.) equal to or slightly longer (c. 3 mm) than primary coverts; 2nd primary shorter than 3rd by c. 2 mm. In *exuber* group 1st primary never less than 18 mm longer than primary coverts; 2nd primary at least 6 mm shorter than 3rd (Meinertzhagen).

MEASUREMENTS

	Wing	Tarsus	Tail
♂♀	c. 115-123	c. 25	85-95 mm (Hartert)

Females usually somewhat smaller

Weight 2 ♂♂ 42, 48; 2 ♀♀ 46, 46 g (Paludan, Afghanistan).

COLOURS OF BARE PARTS. Iris brown. Bill, legs, feet and claws black.

938. Chestnutrumped Shrike. *Lanius collurio* Lesson

Lanius collurio Lesson, 1832, in Bélanger, Voy. Ind.-Orient., Zool.: 250-1 (Pegu)
Baker, FBI No. 711, Vol. 2: 291
Plate 66, fig. 10

LOCAL NAMES. None recorded in India.

SIZE. Bulbul ±; length c. 23 cm (8½ in.).

82

LANIIDAE

935. Persian Grey Shrike. *Lanius excubitor aucheri* Bonaparte

Lanius aucheri Bonaparte, 1833, Rev. Mag. Zool. 5: 294 (Persia)
Baker, FBI No. 708, Vol. 2: 288

LOCAL NAMES. None recorded.

SIZE. Myna ±; length c. 25 cm (9½ in.) including long tail.

FIELD CHARACTERS. As in 933, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. A scarce winter visitor to N. Baluchistan; more common in central and coastal Makran, from the valley of the Hingol westward. Arrives early September. Affects semi-desert scrub country.

Extralimital. West coast of the Red Sea in Eritrea, Ethiopia, and Somalia. N. Arabia, Sinai Peninsula, Palestine, Iraq, S. Iran, etc. For particulars see Vaurie, 1959, 2: 113.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 933.

BREEDING. Extralimital; as in 933.

MUSEUM DIAGNOSIS. Frontal black band narrower; grey of upperparts uniform, not paling on rump and upper tail-coverts as in *lahtora*. Lesser coverts grey; inner edge of inner web of secondaries usually white the rest brown, but this rather variable. Underparts with a greyish wash.

Young (immature). Above, pale grey washed with isabelline; ear-coverts dark brown. Below, white washed with cream on breast and with a few shadows of dark barring; wing-coverts and tertials dark brown tipped with buffish white.

MEASUREMENTS

	Wing	Tail
♂♀	107-116 (mostly 106-110)	c. 106-118 mm (Hartert)

COLOURS OF BARE PARTS. As in 933.

936. Turkestan Grey Shrike. *Lanius excubitor homeyeri* Cabanis

Lanius Homeyeri Cabanis, 1873, Jour. f. Orn. 21: 75 (Sarepta)
Lanius excubitor var. *leucoptera* Severtzov, 1875, Stray Feathers 3: 430
(Upper Naryn River, Turkestan)
Lanius Przeczalskii Bogdanov, 1881, Wur. der Russ. Faun.: 147 (Tashkent)
Baker, FBI No. 709, Vol. 2: 289

LOCAL NAMES. None recorded.

SIZE. Myna ±; length c. 25 cm (9½ in.) including long tail.

FIELD CHARACTERS. As in 933, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Vagrants recorded between November and January only from Baluchistan (Quetta), Gilgit, and Kashmir (Avantipur near Srinagar — F. Ludlow); perhaps driven south in hard winters.

Originally identified, possibly quite correctly, as *homeyeri*, the specimens not now available for re-examination. However, assigned by Vaurie to *leucoptera* which he recognizes as distinct. He describes *leucoptera* as similar to *homeyeri* but distinctly paler, with the rump and upper tail-coverts white, not grey or tinged with greyish, and with the white area in the wing very much larger. It is also said to average very slightly larger: Wing 10 ♂♂ 116-123 (av. 118.5) c. 10 ♂♂ of *homeyeri* Wing 113-119 (av. 115) mm. Further specimens needed for study.

84

LANIIDAE

FIELD CHARACTERS. Male. Above, forehead, lores, ear-coverts and around eyes black, shading to dark ashy on crown and paling on nape and sides of neck; rest of upperparts chestnut. Wings blackish brown with a white 'mirror' or speculum conspicuous in flight. Below, chin, throat and under tail-coverts white; rest pale fulvous or whitish. Tail black-and-white, the two central pairs of rectrices tipped with rufous, the others with whitish.

Female like male but lores and nasal feathers whitish.

STATUS, DISTRIBUTION AND HABITAT. Passage migrant in the plains and foothills of eastern Assam (Cachar dist.), Nagaland (?), Manipur, and perhaps East Pakistan. Records of breeding in N. Cachar need confirmation. Affects gardens, secondary jungle and outskirts of cultivation.

Extralimital. Burma, Thailand, Yunnan, Indochinese countries.

GENERAL HABITS. Typical shrike, cf. 933. Usually met with singly, perched on a dead tree-stump, telegraph wire or other point of vantage, swaying its tail, darting to the ground every now and again to take an insect, and often returning to the same perch.

FOOD. Grasshoppers and other insects, lizards and small terrestrial animals.

VOICE AND CALLS. Harsh grating as well as musical notes. Song, described as 'sweet and full'.

BREEDING. Extralimital.

MUSEUM DIAGNOSIS. See Key to the Species and Field Characters.

Young (immature). Above, whole head dark brown, the forehead feathers with tiny pale centres and all with small pale tips; rest of upperparts, median and lesser coverts rufous, barred with dark brown; rest of wings dark brown with fulvous instead of ferruginous edges; white bases of flight-feathers rather less than in adult. Tail pattern as in adult but brown replaces black and the white is sullied by rusty; rectrices narrower and more pointed. Postjuvenile and postnuptial moults complete; August to October. No spring moult (Ticehurst MSS.).

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂♀	85-94	17-19	c. 25	92-102 mm (CBT)

COLOURS OF BARE PARTS. Iris reddish brown. Bill horny brown, black at tip and on culmen, flesh at base. Legs and feet dark slate.

LANIUS VITTATUS Valenciennes

Key to the Subspecies

Paler above and averaging larger.....*L. v. nargianus*
Darker above and smaller.....*L. v. vittatus*

939. Baluchistan Baybacked Shrike. *Lanius vittatus nargianus* Vaurie

Lanius vittatus nargianus Vaurie, 1955, Amer. Mus. Novit., No. 1752: 10
(Champur, southern Persian Baluchistan)
Baker, FBI No. 710, Vol. 2: 289 (= *vittatus*)

LOCAL NAMES. *Nargiani* (Baluchi); *Gmeh* (Brahui).

SIZE. Bulbul; length c. 18 cm (7 in.).

SHRIKES

85

FIELD CHARACTERS. As in 940, q.v. See *Museum Diagnosis*.

STATUS, DISTRIBUTION and HABITAT. Resident throughout central and coastal Makran south of Las Bela and in the Sibi Plain. Summer (breeding) visitor to N. Baluchistan, arriving end March, departing August/September, ascending some of the higher hills to c. 1600 m. Intergrades with nominate *rittatus* in Sind and NW. Punjab. Affects open scrub country and outskirts of cultivation.

Extralimital. Adjoining Persian Baluchistan, E. Persia and S. Afghanistan. Reported from Transcaspi.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 940.

BREEDING. Season, April to June. Nest, eggs and breeding biology as in 940.

MUSEUM DIAGNOSIS. 'Paler above in both sexes than nominate *rittatus*; averaging larger, in 10 ad. ♂♂ (paratypes), wing 86-92 (88.8), bill 17-20 (18.5), as against 82-88 (85.5) and 15.5-18 (16.5) in 10 ♂♂ from southern Madras' (Vaurie). Weight 1 ♂ 26 g (Paludan, Afghanistan).

COLOURS OF BARE PARTS. As in 940.

940. Indian Baybacked Shrike. *Lanius vittatus vittatus* Valenciennes

Lanius vittatus Valenciennes, 1826, Dict. Sci. Nat., ed. Levrault 40: 227 (Pondicherry) Baker, FBI No. 710, Vol. 2: 289 Plate 66, fig. 6

LOCAL NAMES. *Pāchānāk* (Hindi); *Pāchnāk lātor* (Gujarati); *Boro* (Sindi); *Chhota kilator*, *Khayrī kārkatā* (Bengali); *Chinna bilinki*, *Venne dega* (Telugu); *Kichān kūrūci* (Tamil); *Anurakili* (Malayalam).

SIZE. Bulbul; length c. 18 cm (7 in.).

FIELD CHARACTERS. Smaller than Rufousbacked Shrike. Above, head white-and-grey with a broad black band across forehead encircling eye and reaching back to end of ear-coverts; back chestnut-maroon; rump whitish. Below, white; fulvous on breast, rusty on flanks. Sexes alike, but frontal band somewhat narrower in female.

Small size, chestnut back, white rump, contrasty black-and-white tail, and roundish white 'mirrors' on black wings diagnostic in flight.

Immature birds with rufous tail and minus white wing-mirror, confusingly like Pale Brown or Rufous shrikes (942, 943) but usually show some grey on lower rump.

STATUS, DISTRIBUTION and HABITAT. Resident, with marked seasonal movements, particularly in the northern parts. All India and W. Pakistan from along the outer Himalayan ranges (to c. 2000 m) — including Chitral, Kashmir south of Pir Panjal range, and Nepal terai — south throughout the Peninsula to Kanyakumari, and from Sind eastward to West Bengal; plains and hills. Not Assam, East Pakistan or Ceylon. Affects dry open scrub country and outskirts of cultivation. Preferential habitat intermediate between dry semi-desert of Grey Shrike (933) and wooded, well-watered facies of Rufousbacked (946).

GENERAL HABITS. Typical shrike. Very parochial, inhabiting the same beat day after day and jealously guarding it against interlopers. Usually

SHRIKES

87

First-year. A dull edition of adult except for the unmoulted parts of wing and tail. Frontal black band may be absent; band through eye may be brown; nape to mantle may be washed with ashy grey; sides of breast may be marked with dark crescents. Some may breed during next spring in this dress, others presumably moult to adult (Tiechurst MSS.).

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	82-90	15-18	21-24	81-96 mm (usually under 90) (SA, HW)

Weight 17 ♂ ♀ 18-24 (av. 20.8) g — SA, BB.

COLOURS OF BARE PARTS. Iris brown. Bill dark horny brown or black (in immature paler at base of lower mandible); mouth pink (in imm. yellow). Legs, feet and claws plumbeous- or horny black, paler in immature.

LANTUS COLLURIO Linnaeus

Cf. Stegmann, B., 1930, *Orn. Monatsb.* 38: 106-18

Key to the Subspecies

	Page
A Tail black and white; back chestnut contrasting with ashy head and nape	87

1 A conspicuous wing-patch	88
2 Wing-patch concealed	89

941. Redbacked Shrike. *Lanius collurio collurio* Linnaeus

Lanius Collurio Linnaeus, 1758, Syst. Nat., ed. 10, 1: 94 (Sweden)
L. (lanius) collurio pallidifrons Johansen, 1932, Jour. f. Orn. 92: 199
(Tomsk, West Siberia)
Baker, FBI No. 717, Vol. 2: 298
Plate 66, fig. 13

LOCAL NAMES. None recorded.

SIZE. Bulbul —; length c. 17 cm (7 in.).

FIELD CHARACTERS. Male (adult), confusingly similar to Baybacked Shrike (940) in size and coloration. Distinguished from it by absence of white wing-speculum and by greater amount of white in tail.

Female (adult), like male but duller; usually without the black band through eye.

Young birds impossible to differentiate in the field from immature *phoenicuroides* (942); for distinguishing in the hand see *Museum Diagnosis*.

STATUS, DISTRIBUTION and HABITAT. Regular autumn passage migrant in small numbers through W. Pakistan and extreme western Rajasthan and N. Gujarat via Arabia and east Africa to its winter quarters in Africa. Recorded in Gilgit, Sind (Karachi), N. Gujarat (Banaskantha, Kutch, Saurashtra). Return passage in spring evidently largely misses out these parts: only sporadic solos sight-recorded in Kutch (end March) and at Quetta (May). Affects open scrub jungle and outskirts of cultivation.

86

LANIIDAE

seen solitary or in separated pairs keeping a look-out for prey from some exposed perch — bush-top, dead tree or telegraph wire — swinging its tail from side to side, dropping to the ground now and again to seize its quarry and returning to the same or a nearby perch. Quarry held underfoot and torn to pieces with the sharp hooked bill before being devoured. 'Larders' less common than in Grey or Rufousbacked shrikes.

FOOD. Caterpillars, beetles, ants and other Hymenoptera and Neuroptera. Also large insects, e.g. crickets and grasshoppers, as well as lizards, and occasionally young mice and nestling birds.

VOICE and CALLS. Normally a harsh, rather scolding *chur-r* or *chee-ur*, sometimes sounding very like the squealing of a frog caught by a snake. In breeding season a pleasant, rambling, warbling song (♂) interlarded with faithful mimicry of many other birds' calls.

BREEDING. Season, overall February to September; chiefly February to April in South India, May to July elsewhere. Nest, a neat compact cup of grass, rags, wool, tow and feathers with much cobweb on the exterior as binding material. Placed at moderate heights (c. 2 to 4 m up) in the fork of a thorn tree such as *Acacia*, *Prosopis* or *Zizyphus*. Eggs, 3 to 5, very variable in coloration and markings; commonest type pale greenish white, thickly blotched and spotted with purplish brown, especially at the broad end. Average size of 100 eggs 20.8 × 15.7 mm (Baker). Both sexes share in building the nest, incubation (?) and feeding the young. Incubation period undetermined. Often two broods raised in a season, usually with a fresh nest for each.

Courtship. Male alights close to female on a branch, the two sometimes almost touching each other. He cranes out his neck stiffly and with tail partially cocked utters harsh excited cries, his face turned away from the female the while but obviously talking 'at' her. She remains seemingly unconcerned, and while being serenaded may even fly down to the ground to pick an insect and back to a different perch. Here she is promptly followed by the male who repeats his amorous antics. He may vary the harsh cries by the pretty warbling mimicking song. His face still remains turned away from her during the performance but his body inclined towards her in a sidling posture. Every little while she utters a harsh *chee-ur* (of approval or encouragement?) whereupon the male hops stiffly a couple of centimetres closer to her, maintaining the same rigid stance of head and body. Copulation probably follows, but not observed. Sometimes two males may pay court in this manner to the same female, each making a sudden dash at his rival betweenwhiles in an attempt to beat him off.

MUSEUM DIAGNOSIS. See keys to the Species and Subspecies, and Field Characters.

Young (immature). Upperparts mealy grey, tinged rufous on mantle and upper tail-coverts, and all with dark bars and pale tips; ear-coverts brown; greater coverts and tertials rufous with pale tips and dark contour lines; primary coverts and flight-feathers dark brown with pale tips and narrow rufescent outer edges; a faint indication of white wing-patch of adult (in ♂ only?). Tail rufous with subterminal dark brown contour lines and pale tips; outer pair of rectrices rufous-white. Below, white with variable amount of dark wavy bars on flanks and breast. Postjuvinal moult includes body, all wing-coverts except primary-, tertials and a variable number of tail-feathers.

88

LANIIDAE

Extralimital. Most of Europe, east to W. Altai, south to Caucasus, Asia Minor, Iran. Winters in tropical and S. Africa.

GENERAL HABITS, FOOD, VOICE and CALLS. Typical of the family.

BREEDING. Extralimital; largely as in 940.

MUSEUM DIAGNOSIS. See keys to the Species and Subspecies; for details of plumages, and bionomics, Witherby, 1938, 1: 292-6; Baker, loc. cit.

Young (immature). Above, buff to rufous, barred with black crescents; ear-coverts dark brown; wing-coverts and tertials dark brown with rufous edges and tips and subterminal dark contour lines. Tail as in adult female (i.e. brown, all but the two central pairs of rectrices with narrow white tips and edges and dark subterminal contour lines) but more rufous. Below, creamy white with dark crescents on breast and sides.

In the hand young bird can be told apart from immature *phoenicuroides* by being more barred and more rufescent above. Tail darker rufous; outer web of outer rectrices white, not rufous.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♂	88-98	12-14	22-25	70-82 mm
♀ ♀	87-96	—	—	— mm (Witherby)

COLOURS OF BARE PARTS. Iris dark brown. Bill black (♂), brown (♀ and imm.). Legs, feet and claws blackish (♂), brownish grey (♀ and imm.).

942. Rufous Shrike. *Lanius collurio phoenicuroides* (Schalow)

Otomela phoenicuroides Schalow, 1875, Jour. f. Orn. 23: 148 (Tschimkent)
Baker, FBI No. 722, Vol. 2: 303
Plate 66, fig. 8

LOCAL NAMES. *Lāl lātor* (Quetta); *Ganj* (Brahui).

SIZE. Bulbul —; length c. 17 cm (7 in.).

FIELD CHARACTERS. Pale sandy brown above, buffy whitish below, with rusty red rump and tail. Closely resembles Pale Brown Shrike (943), but crown rufous-brown contrasting with sandy brown back. Supercilium usually more distinct and white; lores and band through eye black; white speculum usually more prominent. Underparts white with a rosy tinge.

Female. Like male but rather less bright above and with some fine brown squamations on underparts. Eye-streak and speculum less pronounced.

Young birds impossible to differentiate in the field from immature *collurio* (941); for distinguishing in the hand see *Museum Diagnosis*.

STATUS, DISTRIBUTION and HABITAT. Breeds in West Pakistan in the hills of NE. Baluchistan near Quetta (Murda, Takatu, Khaliphath, Ziarat) between c. 2000 and 3000 m. Regular autumn passage migrant in NW. Frontier districts, Gilgit, S. Punjab, Makran, Sind, Rajasthan (Mount Abu, Jodhpur); small numbers overwintering (September to March) in N. Gujarat and Kutch where intermediates between this form and *isabellinus* have been collected. Affects sparsely scrubbed semi-desert.

Extralimital. Mountains of Turkestan, Tien Shan, Pamirs, Transcaspi, Dzungaria, N. Afghanistan, Iran. In winter to Arabia and NE. Africa

SHRIKES

89

(Sudan, Ethiopia, etc.). For further particulars of range see Vaurie, 1959, 2: 98.

GENERAL HABITS, FOOD, VOICE and CALLS. Typical of the shrikes, cf. 933, 940.

REEDING. Season, in Baluchistan April to June. Nest, a massive cup of fine flexible twigs, grass, fibres, etc. and untidy bits of wool and rags where available, lined with soft grass or hair. Placed in the centre of a low thorny bush or in the fork of a branch with the main stem of a roadside tree, 3 to 5 metres up. Eggs, 5, occasionally 6, as typical of the shrikes (cf. 940), greenish white with the usual variations. A variety with salmon-pink ground reported as common in the Quetta neighbourhood. Average size of 20 eggs 22.8 × 16.2 mm (Williams).

MUSEUM DIAGNOSIS. Compared with *isabellinus* (943) wing-coverts darker; upper tail-coverts and tail more foxy red; outermost rectrices fall short of tail-tip by 10-16 mm.

Compared with *cristatus* (949) tail more foxy red; crown and back contrasting, not uniform rich russet brown; outermost rectrices longer.

Young (immature). Like female but less contrast between crown and upperparts; a good deal of dark and pale cross-barring on upperparts and lesser coverts; greater coverts, tertials and tail with dark submarginal contour lines and pale tips. Underparts with ochraceous tinge and dark squamate markings except on throat and under tail-coverts. Not so saturated above as in *cristatus* (Ticehurst MSS.).

In the hand young bird can be told apart from immature *collurio* (941) by being less barred, less rufescent above. Tail paler rufous; outer web and tip of outer rectrices rufous, not white.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	91-97	17-20	25-27	78-85 mm
♀♀	90-94	17-20	24-25	78-83 mm (SA)

Weight 7 ♂♂ 24-29; 5 ♀♀ 25-28 g (Paludan, Afghanistan); 4 co? (Nov./Dec.) 28-34 g — SA, Kutch.

COLOURS OF BARE PARTS. Iris dark brown. Bill black. Legs, feet and claws black. In immature bill horn brown above, flesh-coloured below.

943. Pale Brown Shrike. *Lanius collurio isabellinus* Hemprich & Ehrenberg

Lanius isabellinus Hemprich & Ehrenberg, 1833, Symb. Phys. Avium fol. c. (Kunfuda, Arabia)

Baker, FBI No. 721, Vol. 2: 302

Plate 66, fig. 7

LOCAL NAME. *Mulkalo* (Sindi).

SIZE. Bulbul —; length c. 17 cm (7 in.).

FIELD CHARACTERS. A pale sandy brown shrike with rusty red rump and tail; very similar to the Rufous (942) but uniformly coloured above, without the contrast between crown and back.

Male. Feathers at base of upper mandible, lores and supercilium fulvous white; a spot in front of eye, and ear-coverts black. A hidden white speculum

SHRIKES

91

LANIUS TEPHRONOTUS (Vigors)

Cf. Dunajewski, A., 1939, *Jour. f. Orn.* 87: 38; Mayr, E., 1947, JBNHS 47: 125-7; Biswas, B., 1950, *ibid.* 49: 444-55

Key to the Subspecies

Back dark grey; rufous more extensive, generally up to the hind-most scapulars..... *L. t. lahulensis*
Back slaty; rufous less extensive..... *L. t. tephronotus*

944. Ladakh Greybacked Shrike. *Lanius tephronotus lahulensis* Koelz

Lanius tephronotus lahulensis Koelz, 1950, Amer. Mus. Novit., No. 1452: 7 (Kolung, Lahul, Punjab, India)

Baker, FBI No. 716 (part), Vol. 2: 297

LOCAL NAMES. None recorded.

SIZE. Bulbul+; length c. 25 cm (10 in.).

FIELD CHARACTERS. As in 945, q.v. See Key to the Subspecies and Museum Diagnosis. Confusingly like *L. s. caniceps* (947) of southern peninsular India but grey of upperparts darker, and usually only rump and upper tail-coverts cinnamon. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Resident and altitudinal migrant. Northern Kashmir, Baltistan, east to Ladakh (Kargil and Suru valleys), and Himachal Pradesh (Lahul, Spiti, Kulu, etc.). Breeds between c. 2700 and 3300 m; descends to lower elevations in the NW. Himalayas in winter. Affects open scrub and secondary growth in and around abandoned hill cultivation clearings.

Extralimital. Probably adjacent western Tibet.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 945.

REEDING. Season, chiefly June and July. Nest, an untidy bulky cup, largely composed of wool intermixed with thorny twigs, grass, rags and feathers bound together with fibres; usually lined with fine grass stems. Placed 1.5 to 3 metres or so up in a fair-sized thorn bush or small tree (*Berberis*, *Hippophae*, etc.). Position usually given away by the birds' harsh scolding chatter in the vicinity. Eggs, 4 to 6, somewhat variable in ground colour, most commonly pale grey-green blotched and spotted with grey-brown or brown, with numerous secondary markings of lavender and grey. Average size of 200 eggs [including those of the Tibetan form (943)] 24.9 × 18.7 mm (Baker).

MUSEUM DIAGNOSIS. Similar to nominate *tephronotus* but paler grey above, and usually with a white area at the base of the primaries (which is lacking or very poorly indicated in nominate *tephronotus*). Bill weaker, more slender and not so high. Averages somewhat smaller: Wing 10 ♂♂ 93-103 (97) mm, as against 98-105 (100.5) mm in 10 ♂♂ of nominate *tephronotus* (Vaurie).

MEASUREMENTS

	Wing	Bill (from skull)	Tail
17 ♂♂	92-103 (av. 95.9)	20-23 (21.3)	109-120 mm (115.8)
6 ♀♀	93-96 (94.9)	21-23 (22)	105-111 mm (108.8) (BB)

COLOURS OF BARE PARTS. As in 945.

90

LANIIDAE

at base of brown primaries, barely visible in flight. Tail dull rufous, the central rectrices browner. Below, pale fulvous, richer on flanks.

Female. Like male but with eye-spot and ear-coverts brown instead of black. Wing-speculum usually absent; underparts sometimes with faint dark squamations on breast.

Young (immature). Field identification unsatisfactory; see Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Winter visitor (September/October to March) and passage migrant. Plains of W. Pakistan and NW. India in Baluchistan, W. Punjab, Sind, Rajasthan, Gujarat (including Kutch and Saurashtra), south through Maharashtra to Nasik and Greater Bombay: chiefly west and north of a line from Khandesh through Sehore (M.P.) to Gorakhpur (U.P.). Stragglers recorded from Nepal, N. Bengal (Jalpaiguri), Bihar (Darbhanga), and eastern Madhya Pradesh (Raipur). Rare in Ladakh (Osmaston, JBNHS 31: 988); evidently not found in Kashmir or normally in the NW. Himalayas. Affects cultivation-outskirts in semi-desert, scanty babool and tamarisk jungle, etc.

Extralimital. From Issyk-kul and Dzungaria west through the plains of Turkestan to the Kirghiz Steppes. Winters largely in Arabia and NE. Africa.

GENERAL HABITS, FOOD, VOICE and CALLS. Typical of the family, cf. 933, 940.

REEDING. Extralimital. Recorded by Meinertzhagen as breeding near Quetta, in addition to *phoenicuroides* (1914, JBNHS 23: 363). However, confirmation has been lacking, and in his *Birds of Arabia* (1954: 173) *isabellinus* is referred to merely as wintering in NW. India (second thoughts!).

MUSEUM DIAGNOSIS. See keys to the Species and Subspecies, and Field Characters. 2nd primary (as.) equal to, or just longer or shorter than 5th (Ticehurst).

A good distinction between *isabellinus* and *phoenicuroides* on the one hand and *cristatus* on the other is the comparative shortness of the outermost rectrix in the former: from tip of this feather to tail-tip 10-16 mm in *isabellinus* (and *phoenicuroides*), 19-24 mm in *cristatus*.

Adults of this shrike and *cristatus* (949) have complete moults in both spring and autumn which take place in the winter quarters. Summer and Winter plumages alike.

Young (immature). Supercilium pale and inconspicuous. Upperparts as in adult but finely and sparingly barred with dark brown; dark submarginal contour lines on greater coverts and tertials, but those on tail hardly visible; pale tips to primary coverts. Below, dull white spangled with brown crescentic bars.

MEASUREMENTS

	Wing	Tail
9 ♂♂	89-94 (av. 91.0)	76-84 mm (av. 79.2)
4 ♀♀	86-95	70-81 mm (Paludan)

Weight 1 ♂ 26 g (BB). 3 ♂♂ 28-33; 3 ♀♀ 27-32 g (Paludan, Afghanistan). Bill (from skull) 18-20 mm (SA).

COLOURS OF BARE PARTS. Iris dark brown. Bill dark brown above and at tip, horn-flesh colour on rest. Legs, feet and claws slaty black.

LANIIDAE

92

945. Eastern Tibet Greybacked Shrike. *Lanius tephronotus tephronotus* (Vigors)

Collurio tephronotus Vigors, 1831, Proc. Zool. Soc. London: 43 (Himalayas, restricted to Gyantse, Tibet, by Baker, 1924, FBI 2: 297; re-restricted to 'Foothills of the Himalayas near Darjeeling, where breeding birds of the Gyantse district may be expected to winter' by Mayr, 1947, loc. cit.: 127)

Lanius nipalensis Hodgson, 1837, Ind. Rev. 1: 445 (Nepal)

Baker, FBI No. 716, Vol. 2: 297

Plate 66, fig. 15

LOCAL NAMES. *Bhadraya* (Nepal hills); *Bagaya tentha* (Nepal plains); *Sakrik pho* (Lepcha); *Tolera* (Bhutanese); *Tré tré* (Tibetan).

SIZE. Bulbul +; length c. 25 cm (10 in.).

FIELD CHARACTERS. Superficially very like Rufousbacked Shrike. Above, narrow forehead and a broad band through eyes to ear-coverts black. Crown, nape, hindneck, and back dark leaden grey or slaty. Rump and upper tail-coverts rufous, this colour not extending beyond rump; tail chestnut-brown. Wings black, only sometimes with an insignificant white patch or 'mirror'. Below, rufous, paler on abdomen. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Breeds in Garhwal, Kumaon and eastward through Nepal (?), Sikkim, Bhutan and NEFA, between c. 2700 and 4500 m. Winters at lower elevations and in the foothills and adjoining plains in Uttar Pradesh, Nepal Valley, Bihar, Madhya Pradesh (straggler), West Bengal, Assam, Manipur, and probably northern E. Pakistan. Affects open scrub, semi-cultivation, gardens and orchards.

Extralimital. Breeds also in eastern Tibet north to Sikang, south to N. Yunnan, east to W. Szechuan. Winters in Burma, S. Yunnan, N. Thailand and the Indochinese countries. For details see Vaurie, 1959, 2: 105.

GENERAL HABITS. A high-elevation shrike, descending to its winter quarters in September/October and leaving again by March/April. Habits and behaviour typical of the family; very similar to those of Rufousbacked and South Indian Greybacked shrikes (946, 947) q.v. Seen singly or in widely separated pairs keeping a look-out for creeping prey from bush-tops. Noisy and conspicuous. Has jealously guarded feeding territories where intrusion by others of its kind is actively resented. On disturbance or alarm drops from its perch and flies with rapid wing-beats flat along the ground sweeping upward to settle on another vantage point a hundred metres or so away.

FOOD. Crickets, grasshoppers, caterpillars and other insects; lizards, nestling birds, baby mice, etc. Also maintains 'larders' of surplus food impaled on thorns.

VOICE and CALLS. Harsh grating cries as if seized by hawk; most noisy towards sunset. Also mimics other birds' calls.

REEDING. Season, nest and eggs (c/3-6) as in 944.

MUSEUM DIAGNOSIS. Like *lahulensis* (944) but somewhat larger, darker, more slaty grey above. Bill stouter. White supercilium and white wing-spot often, but not always, absent. Rufous on lower plumage usually richer and more extensive than in *tephronotus*.

Postnuptial moult completed by December and some, apparently first year birds, perform a complete moult in April (CBT).

SHRIKES

93

Young (immature). Breast, belly and flanks more or less spangled with narrow dark brown bars; some indication of this also on upper tail-coverts. As in *erythronotus* there is variation in the white wing-spot, white supercilium, tail, and in the amount of postjuvénal moult.

MEASUREMENTS				
	Wing	Bill (from skull)	Tarsus	Tail
♂ ♀	95-108	20-23	28-30	102-119 mm (SA, BB, HW)

Weight 8 ♂♂ 39-51; 4 ♀♀ 43-54 g (GD, SA, BB).
COLOURS OF BARE PARTS. Iris brown. Bill horny brown or black, paler at base of lower mandible. Legs, feet and claws horny black.

1 Upper back more or less suffused with rufous..... <i>L. s. erythronotus</i>	93
2 Upper back with no tinge of rufous..... <i>L. s. caniceps</i>	96

946. Rufousbacked Shrike. *Lanius schach erythronotus* (Vigors)

Collurio erythronotus Vigors, 1831, *Proc. Zool. Soc. London*: 42 (Himalayas, restricted to Lucknow by Baker, 1924, FBI 2: 295; re-restricted to Simla-Almora dist. by Ticehurst & Whistler, 1924, *Ibis*: 468-73)
Baker, FBI No. 714, Vol. 2: 295
Plate 66, fig. 17

LOCAL NAMES. *Mattiya latora*, *Kajala latora* (Hindi); *Majhla latora* (Saugor, M.P.); *Hara wataj* (*wataj* = executioner, Kashmiri); *Terra lilinchi* (Telugu).
SIZE. Bulbul +; length c. 25 cm (10 in.).

FIELD CHARACTERS. A typical shrike with large head, stout laterally compressed hook-tipped bill, and longish graduated tail.
Adult. Above, forehead and a broad band through eye black; crown, nape, sides and hindneck, and upper back clear grey diffusing to rufous or cinnamon on rest of upperparts. Tail black and rufous. Below, chin, throat and upper breast white; rest of underparts pale rufous. Wings blackish with a white wing-spot or mirror, conspicuous in flight. Sexes alike.
STATUS, DISTRIBUTION AND HABITAT. Breeds in W. Pakistan and India, in NE. Baluchistan, Sind, Punjab (NW. frontier districts, Murree hills, Salt Range, etc.), Chitral, Gilgit, Astor, Kashmir, along the outer ranges of the W. Himalayas eastward to Kumaon (Almora dist.) up to c. 3000 m. Arrives early April, leaves c. September. Also breeds in Uttar Pradesh southward to E. Maharashtra (Nagpur); in the west, in Rajasthan and southward through Gujarat and W. Maharashtra to N. Mysore (Belgaum).

SHRIKES

95

cuckoo shrike, purple sunbird (song), koel, pied crested-, hawk-, common and Indian cuckoos, magpie-robin. Other sounds such as call of striped squirrel and yelping of new-born puppies also realistically woven into the song and following one another in smooth succession. Is very quick to learn, and often reproduces the calls long after the originals have left the locality, signifying a remarkably retentive memory.

BREEDING. Season, overall March to July; chiefly April-May in the plains, May to July in Kashmir and elsewhere in the Himalayas. Nest, a bulky, deepish, loosely built cup of thorny twigs, rubbish, dirty rags, wool, hair, bits of papery bark, roots, etc. lined with fine grass stems. It measures c. 18-19 cm across on the outside; diameter of cup c. 7-8 cm, depth c. 5-6 cm. Placed 3 or 4 metres up amongst a cluster of twigs in a willow or thorny tree; occasionally at the base of leaf-stalks in a small date or palmyra palm. Eggs, 3 to 6, usually 4 or 5, somewhat variable in shape, colour and size: mostly greyish or greenish white in ground colour, fairly heavily marked with sepia or dark grey or yellowish brown in a zone at the big end. Average size of 95 eggs 23 x 17.9 mm (Osmaston). Both sexes take part in building the nest, incubation and tending the young. Incubation period undetermined. Often has two successive broods (sometimes three) using the same nest for both. Commonly brood-parasitized by the cuckoos *Cuculus canorus*, *C. varius* and *Clamator jacobinus*.

MUSEUM DIAGNOSIS. See Key to the Subspecies. White wing-speculum large. Rufous of rump extends to mantle; in *caniceps* more or less confined to rump. But there is some variation in the amount of rufous colour in the upperparts, and individual winter specimens are often impossible to place with certainty.

Young (immature). General colour scheme as in adult but feathers of upperparts with narrow dark brown bars, and with ochraceous or fulvous tips on head and neck; band through eye blackish brown (v. black); primary coverts dark brown, rest of coverts dark brown with rufescent tips and edges; flight-feathers dark brown with pale tips; tail brown tinged with rufous, and with paler tips. Below, chin and throat white; rest of underparts cream coloured with dark cross-bars on breast and flanks.

First-year birds recognized by browner wings without the white mirror, browner unmoulted parts of tail, and sometimes a brownish cast to the grey of the upperparts.

MEASUREMENTS				
	Wing	Bill (from skull)	Tarsus	Tail
♂♂	88-98	19-23	27-30	107-127 mm
♀♀	87-95	19-23	25-29	107-119 mm (BB, SA)

Weight 6 ♂♂ 37-41; 5 ♀♀ 33-41 g (Paludan — Afghanistan).
COLOURS OF BARE PARTS. Iris brown. Bill black, flesh coloured at base of lower mandible. Legs, feet and claws brownish black.

LANIIDAE

94

Intergrades with *caniceps* (947) and *tricolor* (948) on the southern and eastern edges of its breeding range.

In much of the above areas commoner in winter, in addition to spreading out then to W. Bengal, Andhra Pradesh (Hyderabad), E. Madhya Pradesh (Bastar dist.), and coastal Makran in Baluchistan. However, the wide overlap of the similar-looking races in winter has resulted in some confusion and ambiguity in the records for the Peninsula.

Affects openly wooded, well-watered country — cultivation, gardens, orchards, roadside hedges, etc. Partial to groves of young date and palmyra palms.

Extralimital. Southern Russian Turkestan, eastward to Ferghana, southward to Transcaspia, NE. Iran, Afghanistan. For particulars see Vauric, 1959, 2: 105-6.

GENERAL HABITS. As of the family. Pugnacious, bold and rapacious; keeps singly or in widely separated pairs, each to its own particular beat or feeding territory, haunting the same day after day all through the season and guarding it fiercely against intrusion by others of its kind. Perches upright on an exposed bush-top, stake, or telegraph wire keeping a sharp look-out for crawling prey. Glides down at an angle, swiftly and silently, to seize the quarry in bill and bear it away. Often pirates food from other birds, even bigger than itself, by bouncing into them bodily while on the ground, knocking them down and making off with the prize before they have recovered from their outraged surprise! Kills young sparrows, mice and other small animals by pouncing and smothering them on the ground and striking viciously and repeatedly on the head with the powerful bill. Often only the brain eaten, the rest impaled on a thorn along with other surplus food as a larder. Will sometimes hawk insects (moths, winged termites, etc.) in the air, launching short sorties from a perch, turning and twisting on the wing in pursuit and returning to base with the quarry.

FOOD. Any small living creature that can be overpowered: crickets, locusts and hoppers, grasshoppers, caterpillars, ants and other Hymenoptera, beetles and other insects; lizards, frogs, fledglings, sickly or disabled birds, young field mice, etc. Also earthworms, and once a two-inch *chilwa* fish (*Chela argentea*). Once reported eating ripe fruit of neem (*Melia* sp.) — Neelakantan, JBNHS 50: 666-7.

VOICE AND CALLS. Vociferous and noisy, particularly in breeding season. Normal notes harsh, grating, complaining cries as if in distress, reminiscent of squealing of frog caught by snake. Note *gritk gritk* or *jultk jultk* followed by a yapping *yaon yaon*. When angry, harsh scolding cries 'closely resembling those of a Corncrake (*Crex crex*) heard in the distance' (Magrath). In breeding season has a beautiful subdued musical song, uttered in the nature of a soliloquy, sustained unbrokenly sometimes for fifteen minutes or more at a stretch. Is an accomplished and versatile mimic of other birds' calls which are freely interlarded in its own song. Among species imitated to perfection the following recorded: pariah kite, common and pied mynas, house and yellowthroated sparrows, swallow, swift, parakeet, redvented bulbul, common, jungle, and yellow-eyed babblers, grey and black partridge, yellow- and redwattled lapwings, common sandpiper, large and small green bee-eaters, baya (chorus), Indian nightjar, rain quail, large

LANIIDAE

96

947. South Indian Greybacked Shrike. *Lanius schach caniceps* Blyth

Lanius caniceps Blyth, 1846, *Jour. Asiat. Soc. Bengal* 15: 302 (India, restricted to Madras by Whistler & Kinnear, 1930, *Jour. Bombay nat. Hist. Soc.* 34: 396)
Lanius schach kathiawarensis Koelz, *Amer. Mus. Novit.*, 1452: 7 (Jamwala, Junagadh, Kathiawar Peninsula, India)
Baker, FBI No. 715, Vol. 4: 296

LOCAL NAMES. Same as for 946; *Kattu karuci*, *Pey karuci* (Tamil).

SIZE. Bulbul +; length c. 25 cm (10 in.).

FIELD CHARACTERS. As of 946, q.v. See Museum Diagnosis.

Immature birds easily confused in the field with various subadult stages of *Lanius collurio phoenicuroides* (942) and *L. c. isabellinus* (943), but *schach* has the upperparts greyer v. browner in the others.

STATUS, DISTRIBUTION AND HABITAT. Resident, subject to local seasonal movements, thus only a winter visitor in parts of its range. NW. Ceylon (dry coastal belt in Jaffna Peninsula and offshore islands). Peninsular India from the extreme south to Kutch and Saurashtra in Gujarat, thence eastward through Madhya Pradesh and Andhra; plains level to c. 1200 m. Intergrades with *erythronotus* at the northern edge of its breeding range. Affects deciduous openly wooded country — cultivation, orchards, date groves, etc.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 946. In Ceylon, frogs reported to be a favourite prey. Also takes mantises (Mantidae) and dragonflies (Libellulidae).

BREEDING. Season, in India chiefly March to May-June (up to July-August in Kutch); in Ceylon December to June, chiefly April-May. Nest, and eggs (c/3 to 6; in Ceylon, 2 to 4) and breeding biology as in 946. Average size of 100 eggs 22.6 x 18.0 mm (Baker).

MUSEUM DIAGNOSIS. Differs from *erythronotus* (946) in having the grey of head and mantle paler and extending down to rump, which alone (with the upper tail-coverts) is cinnamon-rufous. But there is a continuous cline in this character and individual examples are difficult to assign with certainty, especially in winter when there is an intermingling of the subspecies.

MEASUREMENTS				
	Wing	Bill (from skull)	Tarsus	Tail
♂♂	90-98	19-22	26-29	113-127 mm
♀♀	87-95	19-22	26-29	100-118 mm (SA, BB, HW)

Weight 7 ♂♂ 33-38 g (SA).
COLOURS OF BARE PARTS. As in 946.

948. Blackheaded Shrike. *Lanius schach tricolor* (Hodgson)

(*Collurio*) *Tricolor* Hodgson, 1837, *Ind. Rev.* 1 (10): 446 (Nepal, restricted to Kathmandu, Nepal Valley, by Biswas, 1950, loc. cit., below: 451)
Baker, FBI No. 712, Vol. 2: 292 (= *n. nigripes*)
Vol. 6, plate 66 fig. 18

LOCAL NAME. *Sakrik pho* (Lepcha).
SIZE. Bulbul +; length c. 25 cm (10 in.).

SHRIKES

97

FIELD CHARACTERS. A typical shrike with black head and a small white patch or 'mirror' on the blackish wings, particularly conspicuous in flight.

Above, crown, sides of head, nape and hindneck black. Upper back ashy grey changing to light chestnut on rest of upper plumage. Tail black, tipped and margined with rufous. *Below*, cheeks, chin and throat white shading to pale rufous on breast and to bright rufous on rest of lower plumage excepting abdomen which is whitish. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Breeds in the Himalayas between c. 3000 and 4300 m, in Garhwal, Kumaon, Nepal and eastward through Sikkim, Bhutan and NEFA (?). Winters at lower elevations in the above areas (below c. 1700 m) and in the plains of Uttar Pradesh (westernmost record Jagadhri, Ambala dist. — Jones, JBNHS 26: 675), Bihar, Orissa, W. Bengal, Assam, Nagaland, Manipur, and E. Pakistan. Affects open wooded country: light forest, scrub jungle, gardens and orchards, etc. Very partial to tall grassland with scattered bushes.

A large hybrid zone between this and the two preceding forms (946 and 947) occurs in the hills of eastern Uttar Pradesh and western Nepal. [Recorded breeding in W. Bengal (24-Parganas dist.) — S. C. Law, JBNHS 36: 261-2.] Wintering specimens showing intermediate characters have been taken in U.P., Nepal, Bihar, Madhya Pradesh, south to Orissa and northern Andhra in the Eastern Ghats.

Extralimital. Burma, Yunnan, Thailand, Vietnam.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 946, q.v. Keeps singly perched on bush-tops, telegraph wires, etc. whence it makes sallies to the ground for creeping prey. Has the usual harsh chattering and scolding notes of shrikes, but is also a very good songster and accomplished mimic. During the breeding season the male delivers a song of considerable sweetness, range and duration, interlarded with numerous other birds' calls and snatches of song.

BREEDING. Season, April to July, chiefly May and June. *Nest*, as in 946 — a massive, compact cup of grass-stems, thorny twigs, etc., lined with softer grass, roots and fibres; built in shrubs, bamboo clumps or small trees mostly up to c. 6 m from the ground. *Eggs*, 4-6, variable, pink to buff or pale green, blotched and spotted with greyish-, reddish-, or purplish brown, more densely at the broad end. Average size of 200 eggs 23.6 × 17.9 mm (Baker). Both sexes share in building the nest, incubation, and feeding the young. Incubation period, *vide* Baker, 14-15 days.

MUSEUM DIAGNOSIS. See Field Characters and Key to the Subspecies; for a full discussion on *Lanius schach* and its subspecies in SE. Asia — B. Biswas, 1950, JBNHS 49: 444-55.

Young (immature). *Above*, upperparts and sides of head pale ochraceous brown with small black bars on head and larger V-shaped bars on mantle — all with ochraceous tips; lower back and rump pale dull ochraceous with no bars; upper tail-coverts rufous; lores and ear-coverts blackish. *Below*, creamy white with no bars; under tail-coverts tinged fulvous. Wing-coverts dark brown with rusty spots and tips. Tail brown, not black; outer two pairs of rectrices dull fulvous (not black) with rufous-white outer webs sharply defined. Postjuvenile moult of body and apparently all coverts except primary. First-year birds distinguished by juvenal tail (Ticehurst, MSS.).

SHRIKES

99

Lanius cristatus

Winter ranges 1 *cristatus* (949). 2 *lucionensis* (950).

1959, 2: 100.) Winters also in Burma, Thailand, Malay Peninsula, Indo-chinese countries, etc. Some non-breeding birds apparently overwinter in the Andamans.

GENERAL HABITS. Typical of the shrikes, cf. 933, 946. Perhaps more crepuscular than others: commonly seen on the move and hunting till well after dusk, when also it is particularly noisy.

FOOD. Locusts, grasshoppers, crickets and other insects; sickly or fledgling birds, baby mice, lizards, etc. A white-eye (*Zosterops*) has been found impaled in its larder.

VOICE AND CALLS. A harsh loud swearing or scolding *chr-r-r-r* commonly uttered: distinguishable from that of Rufous-backed Shrike. Only sub-song occasionally heard in its winter quarters — a sweet but faint, almost inaudible warbling, like a very subdued and mellow version of the Rosy Pastor's chattering song, with mimicry of other bird-calls interlarded. Singing often detected only by the pulsations of the bird's throat and the accompanying up-and-down vibrations of the tail (SA).

BREEDING. Extralimital. Alleged nesting within Indian limits — N. Cachar and Khasi hills (Baker) — lacks substantiation.

MUSEUM DIAGNOSIS. Differs from *L. c. phoenicuroides* (942) in having the tail browner, and rump and upper tail-coverts concolorous with back v. contrasting rusty red. Most reliably diagnosed from it by comparative lengths of outermost rectrices: distance from tip of this feather to tip of central rectrices 19-24 mm, against 10-16 mm in *phoenicuroides* (and *isabellinus*).

Adults have two complete moults — in spring and autumn — in the winter quarters (cf. *isabellinus*, 943).

Young (immature). Juvenile like that of *Lanius c. phoenicuroides* (942), q.v., but darker, more saturated rufous above. Outer tail-feathers shorter but with the same

98

LANIIDAE

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	93-101	20-23	29-34	115-135 mm
♀♀	92-96	20-23	27-29	106-126 mm (SA, BB)

Weight 8 ♂♂ 39-50; 2 ♀♀ 43, 43 g (SA, GD, Paynter).

COLOURS OF BARE PARTS. Iris dark brown. Bill black, horny or flesh coloured at base in winter. Legs and feet slaty- or brownish black.

LANIUS CRISTATUS Linnaeus

Key to the Subspecies

Crown practically the same colour as back.....	<i>L. c. cristatus</i>
Crown grey	<i>L. c. lucionensis</i>

949. Brown Shrike. *Lanius cristatus cristatus* Linnaeus

Lanius cristatus Linnaeus, 1758, Syst. Nat., ed. 10, 1: 93 (Benghala)

Baker, FBI No. 719, Vol. 2: 300

Plate 66, fig. 9

LOCAL NAMES. *Kārkātā* (all shrikes — Bengali); *Kerkheta* (Hindi); *Batte gādu*, *Batte kiriti gādu* (Telugu).

SIZE. Bulbul ±; length c. 19 cm (7½ in.).

FIELD CHARACTERS. Adult. Entire upperparts including crown, rump and upper tail-coverts reddish brown; forehead and supercilium white; a black line through eyes to ear-coverts. Tail rufous-brown. Wings brownish black, edged rufous; no white 'mirror' or speculum. *Below*, chin, cheeks and throat white; rest pale fulvous, tinged with variable amount of rufescent on breast and belly. Sexes alike.

Some adults have the breast and sides spangled with dark crescentic bars.

Easily confused in the field with the very similar *L. c. phoenicuroides* (942) and *L. c. isabellinus* (943) along its western limits, but is darker and with the tail less red. See Key to the Species and Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Winter visitor. All India including NEFA, Assam, Nagaland and Manipur together with Nepal, Sikkim, Bhutan and E. Pakistan, roughly south and east of a line from Ahmednagar through the Surat Dangs (Gujarat), Mhow (Madhya Pradesh), Lucknow (Uttar Pradesh) and Nepal. Also winters in Ceylon (common), and the Laccadive, Maldivé, Andaman and Nicobar islands (?). From plains level to c. 2100 m in the Himalayas and in the peninsular and Assam hills. Affects forest edges and clearings, secondary scrub jungle and grass-covered hillsides with scattered bushes and small trees etc. in dry-deciduous and semi-evergreen biotope. Arrives chiefly August-September: mostly gone by mid April, some individuals staying on till early June.

Extralimital. Breeds in Siberia from Tomsk to the Kolyma R. and Kamchatka south to N. Mongolia and N. Amurland. (For details see Vaurie,

100

LANIIDAE

dark subterminal contour lines by which first-year birds can always be recognized; these contour lines also present on the greater coverts and tertials.

First-year birds (♂♀) richer, darker and more rufous-brown above than first-year *phoenicuroides*, with the same dark contour lines to tertials and crescentic barring below (Ticehurst, MSS.).

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	85-89	18-20	24-26	78-86 mm
♀♀	80-89	18-20	24-26	78-89 mm (SA, HW)

Weight 3 ♂♂ 30-39; 2 ♀♀ 33, 34 g (GD, Paynter). 14 ♂♀ (winter) 21-35 (av. 28.0) g — SA.

COLOURS OF BARE PARTS. Iris brown. Bill horny brown, paler at gape and base of lower mandible; mouth pale pinkish flesh. Legs and feet plumbeous or bluish grey; claws horny brown.

950. Philippine Shrike. *Lanius cristatus lucionensis* Linnaeus

Lanius lucionensis Linnaeus, 1766, Syst. Nat., ed. 12, 1: 135 (Luzon)

Baker, FBI No. 720, Vol. 2: 302

LOCAL NAMES. Same as for 949.

SIZE. Bulbul ±; length c. 19 cm (7½ in.).

FIELD CHARACTERS. As of *cristatus* (949), q.v., but with forehead and supercilium greyish white; crown greyish brown contrasting with rest of upperparts; rump and upper tail-coverts tinged with rufous. Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Winter visitor (September to April) chiefly to the Andaman and Nicobar islands (common), and Ceylon (occasional or regular?); believed to reach there via the Andamans. One old record for Kerala (Hume, 1876, SF 4: 393). Affects secondary jungle, gardens around habitations, and forest clearings for settlements, hill and plain.

Extralimital. Breeds in Szechuan, E. China, Korea. Winters also in Burma, Thailand, Malaya, Indonesian islands, Philippines, Taiwan, etc.

GENERAL HABITS AND FOOD. As in 949.

VOICE AND CALLS. Harsh chattering as in 949. Song reminiscent of a Sedge Warbler's; also that of Thickbilled Warbler (*Phragmatichela ardor*, 1549) — P. F. Wickham, Burma.

BREEDING. Extralimital. Non-breeding examples taken in the Andamans in June and July suggest possibility of some overwintering there.

MUSEUM DIAGNOSIS. See Field Characters and Key to the Subspecies. Edges of tertials and of secondaries paler rufous than in *cristatus*.

First-year birds have the entire upperparts more greyish brown than in *cristatus*.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂♀	87-92	c. 15	c. 24-25	77-89 mm (Baker)

Wing ♂♀ 90-94 mm (Hartert).

Plate 63, fig. 5

LOCAL NAMES. As for other yellow orioles, cf. 953. *Sathiat* (Assam).
SIZE. Myna; length c. 25 cm (10 in.).
FIELD CHARACTERS. As of 953, q.v. See Key to the Subspecies.

x c. 1

STATUS, DISTRIBUTION and HABITAT. Occasional winter visitor: recorded in Mysore, Kerala, Tamil Nadu, Andhra Pradesh, Assam and E. Pakistan. Ceylon (once). Solos twice sight-recorded in the same residential garden in Bombay City, both in February — 1944 and 1946 (Rev. R. Dyke Acland,

Oriolus chinensis

■ Breeding ▨ Winter

Unnumbered, other races

- 1 *diffusus* (954).
2 *tenuirostris* (955).
3 *andamanensis* (956).
4 *macrourus* (957).

ORIOLES

107

rather surprised *whetow* or a liquid *chuck, tarry-you* (W. T. Loke); 'a curious *maow* like a peevish cat' (Smythies). Also a harsh grating cry, monotonously repeated.

BREEDING. Season, chiefly May and June. Nest and eggs (c/2 or 3), as in 953, the latter described as 'a beautiful pale pink, the markings nearly all surrounded by a reddish halo as if they had run'. Average size of 30 eggs 27.9 × 20.7 mm (Baker). Breeding biology as in 953.

MUSEUM DIAGNOSIS. See Key to the Subspecies.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	142-155	30-33	more or less as in <i>diffusus</i>	(Baker)

Weight 5 ♂ ♀ 2.5-3.25 oz. = c. 72-92 g (Scully, Davison).

COLOURS OF BARE PARTS. Iris blood-pink, eyelids paler. Bill livid pink, brighter in summer. Legs and feet plumbeous; claws black.

956. Andaman Blacknaped Oriole. *Oriolus chinensis andamanensis* Tytler

Oriolus andamanensis Tytler, in Beavan, 1867, Ibis: 326
(South Andamans)

Baker, FBI No. 957, Vol. 3: 10

LOCAL NAMES. None recorded.

SIZE. Myna —; length c. 23 cm (9 in.).

FIELD CHARACTERS. As of 953, q.v.: slightly smaller. See Key to the Subspecies.

STATUS, DISTRIBUTION and HABITAT. Resident; endemic. Andaman Islands. Common and conspicuous, particularly in the South and Middle groups. Affects wooded country — open forest as well as around settlements.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 953.

BREEDING. Season, April to June. Nest, as in 953: the typical deep cup of woven grass and fibres (here often coconut), suspended like a cradle or hammock in a horizontal fork of leafy twigs near the tip of a pliant out-hanging branch, between c. 3 and 6 or 7 m from the ground. 'Nest usually decorated outside with sprays of a small climbing Aselepiad with orbicular leaves' (Osmaston). Eggs, 2 or 3, white generally more or less tinged with claret and with dark purplish brown spots which appear to have run from the edges, and with a few underlying grey spots (Osmaston). Average size of 30 eggs 29.7 × 21.6 mm (Baker). Breeding biology presumably as in 953.

MUSEUM DIAGNOSIS. See Key to the Subspecies.

MEASUREMENTS

♂ ♀	Wing	Bill (from feathers)	Tarsus	Tail
5 ♂ ♂	130-140 (av. 136.6)	29-31	90-104 mm (av. 98)	
1 ♀	133	28	92 mm (HA)	

COLOURS OF BARE PARTS. As in 953.

106

ORIOLIDAE

pers. comm. — subspecies?). Affects mixed deciduous and evergreen secondary jungle, rubber plantations, etc. and well-wooded gardens in urban areas.

Extralimital. Breeds in eastern Siberia (Khabarovsk Province), Ussuriland, Manchuria, NE. China, Korea, Yunnan, N. Vietnam. (For details see Vaurie, 1959, 2: 118.) Winters mostly in the Indochinese countries, Malay Peninsula, Thailand, Burma.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 955.

BREEDING. Extralimital. As in: 955.

MUSEUM DIAGNOSIS. See Key to the Subspecies.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	147-155	28-31	c. 24	89-95 mm (Baker)

955. Slenderbilled Blacknaped Oriole. *Oriolus chinensis tenuirostris* Blyth

O. (riolus) tenuirostris Blyth, 1846, Jour. Asiat. Soc. Bengal 15: 48

(Central India; restricted to Assam by Deignan, 1945, Bull. U.S. Nat. Mus., No. 186: 296)

Baker, FBI No. 955, Vol. 3: 9

Plate 63, fig. 6

LOCAL NAMES. As in 953.

SIZE. Myna; length c. 25 cm (10 in.).

FIELD CHARACTERS. Very like the Golden Oriole (953) — brilliant golden yellow with black in wings and tail — but with the eye-band continued behind to meet over nape. See Key to the Subspecies.

Female duller and greener.

STATUS, DISTRIBUTION and HABITAT. Equivocal. According to Baker 'breeds in the lower Himalayas from Nepal to eastern Assam between the foothills and 6000 ft [c. 2000 m]'. However, there are no definite records of its breeding within Indian limits except Baker's own in the North Cachar and Khasi hills. The statement about the Himalayas needs confirmation since most observers in Nepal, Sikkim and Bhutan have recorded the bird only as a comparatively rare winter visitor (October-March). Apparently winter visitor also to the duars of W. Bengal and adjacent plains; Nagaland; Manipur; E. Pakistan (Chittagong Hill Tracts). Affects open well-wooded country.

Extralimital. Breeds in Burma, Yunnan and N. Laos. Recorded from Thailand in winter.

GENERAL HABITS. Similar to Golden Oriole (953). Arboreal, keeping singly or in pairs to large, well-foliaged and fruit-bearing trees.

FOOD. Fruits, berries and insects. Wild figs (*Ficus* spp.), and berries of *Trema orientalis* specifically mentioned; also nectar of *Salmalia* and *Erythrina* flowers.

VOICE and CALLS. Melodious liquid flute-like notes, similar to Golden Oriole's but with a distinct diagnostic quality. 'A pleasing long-drawn

LOCAL NAMES. *Peelāk*, *Zērdāk* (Hindi); *Pēlārī tēpār peelāk* (Lucknow); *Pēlārī* (Gorakhpur, U.P.); *Bēnē bēnē*, *Hāli pākhi* (Bengali); *Hakhi*, *Heti* (Assamese).

SIZE. Myna; length c. 25 cm (10 in.).

ORIOLES

109

FIELD CHARACTERS. Adult. Brilliant golden yellow with jet black head, throat and upper breast, and some black in wings and tail. Sexes alike, but upperparts of female tinged with olive.

Young (immature) paler. *Above*, forehead yellow, crown and sides of head blackish streaked with yellow. *Below*, chin and throat white, breast yellow, streaked black.

STATUS, DISTRIBUTION and HABITAT. Resident, subject to local movements. The Himalayan foothills (mostly under 1200 m), duns, bhabar, terai, duars and adjoining plains, from Himachal Pradesh (Kangra, c. 76°E.) eastward through Garhwal, Kumaon, Nepal, Sikkim, Bhutan, NEFA (Mishmi Hills); Assam, Manipur, E. Pakistan. The Gangetic Plain and along northern Madhya Pradesh to Bihar and W. Bengal, Andaman Islands (summer)¹. Affects well-wooded country — open forest, mango groves, etc. around habitations and cultivation, gardens and compounds with large trees within urban limits, etc.

Extralimital. Burma south to Tenasserim; Shan States; Thailand. Other races extend the species to the Indochinese countries, Malay Peninsula, Sumatra, Borneo, etc.

GENERAL HABITS. Very similar to those of the Golden Oriole (953). Chiefly arboreal and frugivorous, but also takes insects and will sometimes even descend to the ground for one. Keeps singly or in pairs; in family parties of 3 or 4 after the breeding season until the young can fend for themselves. Often in loose association with mixed hunting parties of insect-eating birds, bulbuls, etc., flying about from tree to tree.

FOOD. Predominantly banyan, peepul and other wild figs (*Ficus* spp.); berries, and flower-nectar (e.g. of *Salmalia*, *Bombax* and *Erythrina* spp.). Also moths, weevils, hemipterous bugs, ants and other insects — same as under 953, q.v.

VOICE and CALLS. A loud, harsh, rather nasal *kwaak*, and melodious fluty whistles like the Golden Oriole's, yet distinctive. Rendered as *uwe-you* (Y, U) or *uwe-you-you*. During the midday heat in the breeding season, male delivers a long-drawn broken song in the nature of a soliloquy from a shady branch (once timed 15 minutes!): a syncopated jumble of mellow fluty notes interspersed with harsh *cheeahs* and *kwaaks*, reminiscent of the Rufousbacked Shrike's compositions (SA). While calling the bird bends low with tail fully spread.

BREEDING. Season, March to August, principally March and April. *Nest*, like the Golden Oriole's — a deep cup of woven grass and bast-fibres, slung like a hammock within a fork of twigs near the end of an outganging branch in some large leafy mango, sheesham or similar tree, 4 to 10 m or so from the ground. *Eggs*, 2 to 4, usually 3, warm salmon-pink in ground colour, spotted with chestnut-brown to deep red-brown, with underlying spots

¹ [960a] Andaman birds, hitherto believed to be summer visitors of the nominate form, have recently been described as *O. x. andamanensis* ssp. nov. (Humayun Abdulali, 1966, JBNHS 63: 421-2).

MUSEUM DIAGNOSIS. Size small, as in *cydonensis*: 6 ♂♂ Wing 122-134; Tail 72-84 mm; 5 ♀♀ Wing 125-130, Tail 76-82 mm.

Deeper yellow than in *cydonensis*; edges to outer webs of inner secondaries yellow v. yellowish white; underparts of female and immature (with streaked throat) apparently as dark as in adult male v. paler in Indian birds (HA).

Separation from Ceylon population on above colour characters seems doubtfully tenable.

ORIOLES

111

MUSEUM DIAGNOSIS. Size intermediate. Yellow on inner secondaries and tertiaries reduced to terminal spots.

First-year birds have a fairly broad yellow frontal band, but yellow edging to feathers of crown and nape much reduced and often absent.

MEASUREMENTS		Wing	Bill (from skull)	Tarsus	Tail
17	♂♂	131-140	27-32	—	82-87 mm (HW)
	♂♂	129-144	28-32	25-27	82-91 mm
	♀♀	130-138	28-31	24-26	83-88 mm (SA)

COLOURS OF BARE PARTS. Adult. Iris blood red or crimson. Bill and mouth livid pink. Legs and feet bluish- or slaty brown; claws black. Young (immature). Iris greyish black. Bill horny black; mouth grey and pale pink. Legs and feet blackish grey; claws horny brown.

960. Ceylon Blackheaded Oriole. *Oriolus xanthornus ceylonensis* Bonaparte

O. (oriolus) ceylonensis Bonaparte, 1850, Comp. Gen. Av. 1: 347 (Ceylon)
Baker, FBI No. 959, Vol. 3: 12

LOCAL NAMES. *Kāhā kūrūllā*, *Woraka maddula* (Sinhala); *Māmbālā kūrūvi* (Tamil)
SIZE. Myna —; length c. 24 cm (9½ in.).

FIELD CHARACTERS. As of 958, q.v. Appreciably smaller. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Endemic in Ceylon. Widely distributed and plentiful locally throughout the well-wooded areas of the lowlands and lower hills to c. 1200 m, occasionally up to c. 2000 m.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 958, q.v. Notes described as 'loud melodious flutings' — *h' yaw haw wheeyou*, the *whee* much higher in the scale than the rest (Henry); a harsh *kwaak* besides.

BREEDING. Season, October to May, chiefly March and April, occasionally August. *Nest* and *eggs* (normally c/2) as in the Indian races, but eggs apparently whiter, only faintly tinged with pink. Average size of 40 eggs 27.0 × 19.4 mm (Baker). Breeding biology as in 958.

MUSEUM DIAGNOSIS. Size small. Yellow on inner secondaries and tertiaries as in 959; reduced to terminal spots. Adult female differs from adult male in being paler, less rich yellow on the upperparts.

First-year birds have the yellow on the head reduced to a narrow or almost obsolete frontal band. In first-year plumage, retained till the second autumn, both sexes have the black of the chin and throat replaced by black and white striping; breast more or less obsoletely streaked; wings duller and more washed with green (Whistler).

MEASUREMENTS		Wing	Bill (from skull)	Tarsus	Tail
17	♂♂	124-135	28-32	23-25	77-84 mm
7	♀♀	123-131	28-30	22-24	75-84 mm (HW)

COLOURS OF BARE PARTS. As in 958.

110

ORIOLIDAE

of dark inky purple. Average size of 60 eggs 28.0 × 19.4 mm (Baker). Both sexes share in building the nest, incubation, and tending the young. Incubation period unrecorded. Commonly builds in the same tree, often even on the same leafy branch, as holds a nest of the Black Drongo (*Dicrurus adsimilis*), doubtless for the protection afforded by these pugnacious birds against nest-robbing crows and other marauders.

MUSEUM DIAGNOSIS. Distinguished (a) by large size, and (b) by the very extensive yellow on inner secondaries and tertiaries forming a broad edging.

First-year birds have a broad yellow band on forehead, accompanied by yellow edging to all the black feathers of crown and nape. May breed in this plumage.

MEASUREMENTS		Wing	Bill (from skull)	Tail
20	♂♂	135-151	30-33	86-100 mm
Female not significantly smaller.				
2	♂♂	143, 143	31, 32	96, 99 mm (HW)
2	♀♀	137, 139	30, 31	92, 93 mm (BB)

Weight 1 ♂ 79 g (BB).

COLOURS OF BARE PARTS. Iris crimson. Bill fleshy pink. Legs and feet deep plumbeous; claws black; pads white (Biswas).

959. South Indian Blackheaded Oriole. *Oriolus xanthornus maderaspatanus* Franklin¹

Oriolus Maderaspatanus Franklin, 1831, Proc. Zool. Soc. London: 118
(Ganges between Calcutta and Benares, and in the Vindhyan Hills, etc., restricted to Jubbulpore by Whistler & Kinnear, 1934, Jour. Bombay nat. Hist. Soc. 36: 585)
Baker, FBI No. 958 (part), Vol. 3: 11

LOCAL NAMES. *Peelāk* (Hindi); *Konda vāṅḡ pāṇḍu* (Telugu); *Mānjūkruppān* (Malayalam).

SIZE. Myna; length c. 25 cm (10 in.).

FIELD CHARACTERS. As of 958, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Resident, subject to local movements. Peninsular India south of the Gangetic Plain, from Gujarat (not north or west of Mount Abu or Saurashtra, though one record from Kutch (Mandvi) — JBNHS 66: 376, and Madhya Pradesh east to southern Bihar, Orissa and Andhra; from plains level to c. 1700 m (sparingly in the Ghats, Nilgiri, Palni and other peninsular hills). Affects well-wooded country in moist-deciduous and semi-evergreen biotope — open forest, village groves, mango orchards, gardens and compounds in towns and cities.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 958.

BREEDING. Season, March to July; sometimes extending into September. *Nest* and *eggs* (c/2 or 3), as in the North Indian (nominate) form.

¹ Subspecies considered questionable by some authors. See Biswas, B., 1949, *Rec. Ind. Mus.* 47: 233-4; Rand & Fleming, 1957, *Firdians*, Zool., 41: 108.

112

ORIOLIDAE

961. Indian Maroon Oriole. *Oriolus traillii traillii* (Vigors)

Pastor Traillii Vigors, 1832, Proc. Zool. Soc. London, pt. 1: 175
(Himalayas-Darjeeling vide Baker, 1921, Jour. Bombay nat. Hist. Soc. 27: 698)
Baker, FBI No. 961, Vol. 3: 14
Plate 63, fig. 7

LOCAL NAMES. *Melambok* (Lepcha); *Tania pia* (Bhutaneese); *Singatee* (Nepali).

SIZE. Myna +; length c. 28 cm (11 in.).

FIELD CHARACTERS. Male (adult), overall glossy crimson-maroon. Head, neck and wings black; tail chestnut-maroon.

Young (immature) male like adult female.

Female (adult), more or less like adult male above, but underparts greyish white streaked with blackish.

In overhead flight against the clear sky appears as a dark bird with square-cut claret-crimson tail.

STATUS, DISTRIBUTION and HABITAT. Resident, subject to seasonal local movements. The lower Himalayas to c. 2400 m from Himachal Pradesh (Kotgarh, c. 77°30'E), eastward through Garhwal, Kumaon, Nepal, Sikkim, N. Bengal (Darjeeling dist. and duars), Bhutan, and NEFA. Assam hills south of Brahmaputra R., Nagaland, Manipur; E. Pakistan (Chittagong Hill Tracts). Affects moist-deciduous and evergreen forest, chiefly in the duars and foothills but extends into adjacent plains.

Extralimital. Burma to Shan States and N. Tenasserim; N. Yunnan; N. and W. Thailand and the Indochinese countries. Another race in Vietnam.

GENERAL HABITS. Very similar to those of the yellow orioles, 953, 958, qq.v. Keeps singly or in pairs much to the tree-tops in high dense forest, chiefly in the foothills; commonly in association with drongos, minivets, nuthatches, etc. Sometimes descends into low bushes or to the forest floor.

FOOD. Wild figs and berries; insects; flower-nectar.

VOICE and CALLS. A harsh *kee-ah*, usually followed by rich liquid fluty whistles like *pi-lo-lo*, indistinguishable from those of the Golden Oriole, but more varied. Some calls reminiscent of snatches of song of *Zoothera citrina*; some others of the rattling 'laugh' of a woodpecker!

BREEDING. Season, principally April and May. *Nest*, a deep massive cup of woven bast fibres bound with cobwebs and suspended hammockwise in the horizontal fork of a branch 4 to 10 m or so up, in thick jungle. *Eggs*, 2 or 3, pinkish white spotted with black or reddish brown. Average size of 24 eggs 29.4 × 20.6 mm (Baker). Both sexes share in building the nest, incubation, and tending the young. Incubation period unrecorded.

MUSEUM DIAGNOSIS. Subadult ♂ has the mantle sullied with black; bases of feathers of upper- and underparts greyish, not snow-white as in adult; traces of dark streaks on belly; outer webs of rectrices black or partly so.

Subadult ♀, like adult but with traces of whitish margins on throat feathers.

MEASUREMENTS		Wing	Bill (from skull)	Tarsus	Tail
♂♂		141-153	31-35	25-27	93-110 mm
♀♀		140-146	29-33	25-26	100-112 mm (SA. BP)

DRONGOS

113

Weight 7 ♂ 67-81; 3 ♀ 67-68 g (SA, GD, BB).

COLOURS OF BARE PARTS. Iris (adult) biscuit colour to creamy white; (imm.) brown. Bill pale bluish grey. Legs and feet plumbeous; claws horny brown.

Family DICRURIDAE: Drongos

For morphological characters and description see Van Tyne, J. & Berger, A. J., 1959: 505; Baker, E. C. Stuart, 1924, FBI 2: 352; Vaurie, C., 1964, Article Drongo¹ in Thomson, A. L. (ed.) *New Dict. Birds*. London & New York.

Genus DICRURUS Vieillot

Dicrurus Vieillot, 1816, Anal. nouv. orn.: 41. Type, by subsequent designation (G. R. Gray), *Ceruus Balicassius* Linnaeus

Chibia Hodgson, 1836, Ind. Rev. 1: 324. Type, by subsequent designation (G. R. Gray), *Edolius barbatus* J. E. Gray = *Ceruus hottentottus* Linnaeus

Bhringa Hodgson, 1836, Ind. Rev. 1: 325. Type, by monotypy, *Bhringa tectirostris* Hodgson

Chaptia Hodgson, 1836, Ind. Rev. 1: 326. Type, by monotypy, *Chaptia muscipetoides* Hodgson = *Dicrurus erurus* Vieillot

Dicrurus Gloger, 1841, Genéin. Hand. Hills. Naturg.: 347. Type, by monotypy, *Cuculus paradisus* Linnaeus

Dicrurorides Hume, 1873, Stray Feathers 1: 408. Type, by original designation, *Dicrurorides dicruriformis* Hume

Dicrurulus Oates, 1889, Fauna Brit. India, Bds. 1: 322. Type, by monotypy, *Dicrurus lephorhizus* Vieillot

Cf. Vaurie, C., 1949, *Bull. Amer. Mus. Nat. Hist.* 93: 205-342

Coloration chiefly glossy jet black; greyish or slaty in some species. Bill stout, sharply carinated; covered at base by dense short feathers partially concealing nostrils. Head uncrested, or with variably pronounced tuft on forehead. Tail variable in shape and structure: long and deeply forked, or with outer rectrices upcurved at end, or prolonged as bare shafts ending in rackets or spatulae. Wings long and pointed, of ten primaries. Legs short with strong toes and sharp curved claws.

Key to the Species

	Page
I Outer rectrices greatly lengthened and part of shafts bare	
A Terminal portion of outermost rectrices equally webbed on both sides	128
B Terminal portion of outermost rectrices much more broadly webbed on the inner than on the outer side (though seemingly vice versa)	135
II Outer rectrices not greatly lengthened; no portion of shaft bare	
C Forehead tufted	
a Tuft composed of a few hair-like feathers more than three centimetres long	131
b Tuft composed of a few hair-like feathers, less than two centimetres long	133
c Tuft composed of ordinary feathers less than two centimetres long	140

DRONGOS

115

(oak, rhododendron, etc.) and openly wooded country, often about cultivation and outskirts of habitations.

Extralimital. Adjacent SE. Iran and E. Afghanistan.

GENERAL HABITS. Arboreal and wholly carnivorous: of great economic usefulness to agriculture in destroying vast quantities of insect pests. Usually seen singly perched on leafless tree-tops, telegraph wires, fence posts, or earthen bunds separating fields. From such exposed look-out posts swoops to the ground for prey or launches sallies in aerial pursuit. Sometimes settles on the ground to pick up ants or winged termites emerging from their holes. Commonly in attendance on grazing cattle or wild herbivores, snatching the insects disturbed by the animals' movements through the grass, riding upon their backs, jogging along complacently with their progress. Often indulges in unabashed piracy, setting upon foraging birds with speed and determination, pursuing them relentlessly with agile twists and turns and forcing them to jettison their lawful prize. Whereupon the drongo retrieves the quarry in mid-air (sometimes in its feet) and calmly flies back with it to a perch, holding the insect down in its claws and tearing it to pieces with the hooked bill before devouring. Considerable numbers will collect at forest fires or fired grassland to hunt the insects fleeing through the rising smoke. Is one of the earliest risers amongst birds, often astir and calling well before dawn; similarly, is one of the last birds to retire, sometimes hunting till well into the dusk: then frequently seen flying up vertically at intervals to snatch a winged termite or other crepuscular insect, diving with closed wings back to the perch. Several birds thus engaged after winged termites is a common sight. Is bold and pugnacious, and very swift and agile on the wing. A pair will fearlessly attack and put to flight large birds like crows, and even raptors, blundering within the precincts of the nest-tree with angry 'war-cries' and much ferocity, the pair manoeuvring in concert, shooting straight into the intruder from below and the sides, diving at it from above and describing circles round it—like fighter planes tackling a heavy bomber—leaving the outraged visitor nonplussed and defenceless while making a hasty getaway. Numbers concentrate to roost in company, particularly during winter, in bamboo clumps etc., the birds dispersing in ones and twos at early dawn for their respective feeding territories. Bathes on the wing, plunging down and dipping at the surface of a pool or stream, then returning to a nearby perch to shake off the water and preen. At approach of breeding season two birds, frequently a trio (sex?), will sit close together or face to face and talk loudly 'at' one another ('argue') in harsh scolding notes, raising head and forepart of body and bobbing violently up and down—like hammering with the bill—and fluttering the wings from time to time as if to emphasize some important point in the argument. The significance of these postures in the courtship behaviour needs study.

FOOD. Predominantly insects; on occasion lizards, small birds (*Prinia*, *Zosterops*, *Agithina* recorded) and small bats (*Microchiroptera*). Very partial to flower-nectar, e.g. of *Salmaia malabarica*, *Bombax insignis*, *Butea monspesia*, *Erythrina* spp., and many others, and from the pollen invariably found on forehead and throat-feathers, doubtless helps in cross-pollination. Moths and butterflies (occasional); of the latter the following identified: *Danaus*

114

Dicrurus macrocerus tripi Koelz, 1954, Contrib. Inst. Regional Exploration, No. 1: 15 (Palasbari, Assam)¹

Baker, FBI No. 767, Vol. 2: 357

LOCAL NAMES. *Bijāngā*, *Būchāngā*, *Kōhāl*, *Kālkālāhi* (Hindi); *Jepāl kalhit* (Punjab); *Finga* (Bengali); *Thampal* (NW. Pakistan); *Kolaho*, *Gohalo* (Brahui); *Charoi*, *Chirai* (Manipur); *Phenchu* (Nowgong, Assam).

SIZE. Bulbul +; length, including long forked tail, c. 31 cm (12½ in.).

FIELD CHARACTERS. Slim, glossy jet black with long deeply forked tail. Sexes alike. When outer tail-feathers moulting (August-September), tail-fork disappears giving the bird a curiously puzzling look.

STATUS, DISTRIBUTION AND HABITAT. Resident, subject to some seasonal local and altitudinal migration. West Pakistan and northern India from Baluchistan east to Kashmir, eastward along the Himalayas to Nepal, Sikkim, Bhutan foothills, Assam, Nagaland, Manipur and East Pakistan. South to Rajasthan, Uttar Pradesh, Bihar and W. Bengal. Intergrades with *macrocerus* (963) in Sind, southern Rajasthan and southern Uttar Pradesh, and with *cathoecus* (of Burma) in SE. Assam and Manipur. From plains level to c. 2100 m in summer (breeding visitor, March/April to September/October), descending to lower altitudes in winter. Affects light hill forest

¹ This name refers to the easternmost population of *albirictus* which here begins to show a trend towards *cathoecus* of Burma.

116

DICRURIDAE

limniace and/or *septentrionis*, *D. aglaea*, *D. chrysippus*, *Euploea coreta*, *E. core*, *Hypolimnas bolina* and *Catopsilia crocale* (Leslie Andrews, JBNHS 20: 850). Among stomach contents of specimens from an intensively cultivated tract in Bihar the following insects (mainly agricultural pests) classified: locusts, grasshoppers and crickets (*Gryllotalpa africana*, *Gryllodes melanosephalus*, *Chrologonus* spp., *Brachytrypus achatinus*), beetles (*Myloecerus discolor*, *M. maculatus*, *Opatrum depressum*), bugs (*Nezara viridula*), ants (*Myrmecocystus setipes*, *Camponotus compressus*, *Oecophylla smaragdina*), termites, bees, etc. (Mason & Lefroy, 1912). Has been observed to capture the ferocious rock bee, *Apis dorsata*.

VOICE AND CALLS. Normal and most common, a defiant-sounding harsh shikra-like double-noted *ti-ti*; also a harsh *cheee-cheee-chick*, and chattering. Particularly noisy at dusk. At commencement of breeding season, indulges in noisy duets *cheee-ti* or *cheee-titi* (*cheee* harsh; rest musical) chiefly during the hour or two preceding daybreak.

BREEDING. Season, overall April to August, principally May and June. Nest, a flimsy-bottomed shallow cup of fine twigs, grasses, bents and fibres cemented together and bound to the substrate with cobwebs. Placed in a horizontal fork of twigs usually near the extremity of a branch between 4 and 12 metres from the ground. Mango (*Mangifera indica*), sheesham (*Dalbergia sissoo*), babool (*Acacia nilotica*) and kandi (*Prosopis spicigera*) in the plains, and oaks (*Quercus*) in the hills—preferably a tree standing by itself in the open with an unobstructed view of the surroundings—are widely favoured. Eggs, 3 or 4, somewhat variable: mostly whitish or pinkish cream, spotted and blotched with black or reddish brown. Average size of 60 eggs 27.1 × 19.8 mm (Baker). Both sexes take part in building the nest, incubation and tending the young. Nests sometimes brood-parasitized by various cuckoos: Drongo-Cuckoo (*Surniculus lugubris*, 588) and Koel (*Eudynamis scolopacea*, 590) thus recorded. Mild mannered birds such as orioles, doves, green pigeons and bulbuls commonly build in the same tree as holds a Black Drongo's nest, thereby profiting from the bird's vigilance and pugnacity in warding off potential marauders.

MUSEUM DIAGNOSIS. The largest-winged and longest-tailed form. White rictal spot usually present. For plumage changes from juvenile to adult, see under *Dicrurus e. macrocerus* (963).

MEASUREMENTS

	Wing	Bill (from skull)	Tail (outer)	Depth of fork
♂ ♀	143-167	24-28	152-180	— mm
				(CBT)
5 ♂ ♂	153-156	25-28	159-172	51-63 mm
3 ♀ ♀	149-153	26 (2)	159-166	48-56 mm
				(BB)

Weight 4 ♂ 39-59; 1 ♀ 41 g (Pahudan, GD).

There is considerable overlap in the measurements of both wing and tail in the sexes, and adult males and females cannot be separated on measurement alone.

COLOURS OF BARE PARTS. Iris blood red to deep crimson (reddish brown to brownish red in first-year birds). Bill, legs, feet and claws black; pads grey (Barnes).

DRONGOS

117

963. South Indian Black Drongo or King Crow. *Dicrurus adsimilis macrocerus* Vieillot

Dicrurus macrocerus Vieillot, 1817, Nouv. Dict. d'Hist. Nat., nouv. éd., 9: 588, based on 'Le Drongolon' of Levaillant, 1805, Ois. d'Afr. 4, pl. 174: 72 (India, restricted to Orissa by Baker, 1924, FBI 2: 356, re-restricted to Madras City by Vaurie, 1949, loc. cit.: 237)

Dicrurus macrocerus peninsularis Ticehurst, 1932, Bull. Brit. Orn. Cl. 53: 20 (Madras City)

Baker, FBI No. 766, Vol. 2: 356
Plate 67, fig. 1

LOCAL NAMES. *Kōlsā*, *Būchāngā* or *Bijāngā*, *Kōtwāl*, *Kālkāldāchi* (Hindi); *Karanjua* (Madhya Pradesh); *Finga* (Bengali); *Kānchh*, *Kālkānchh* (Kutch); *Kunik*, *Kālkāldāchi* (Sind); *Pāsālā pōli gādu* (Telugu); *Kari kārūmān*, *Karihān*, *Karuvattu vali* (Tamil); *Kakka tāmpūrātti*, *Anaranchi* (Malayalam); *Kosita*, *Kālo koshi* (Gujarati); *Chosia*, *Kōtwāl* (Marathi).

SIZE. Bulbul +; length, including long forked tail, c. 31 cm (12½ in.).

FIELD CHARACTERS. As of 962, q.v. See Museum Diagnosis.

× c. 1

STATUS, DISTRIBUTION and HABITAT. Common resident, subject to some seasonal local migration. Throughout peninsular India south of a line roughly from Kutch and Saurashtra eastward through Madhya Pradesh and Orissa to southwest Bengal (intergrading with *albirictus* north of this area). From plains level to c. 2100 m; rarer in the hills. Affects

open deciduous forest and cultivated country, chiefly in the neighbourhood of habitations.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 962.

BREEDING. Season, chiefly March to June/July. Nest, eggs (c/3 or 4, rarely 5), and breeding biology as in the northern form (962).

MUSEUM DIAGNOSIS. Smaller than Himalayan-north Indian *albirictus*; larger than Ceylonese *minor* (964). White rictal spot usually present.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail central outer
♂ ♀	130-145	23-26	—	— 135-161 mm (CBT)
♂ ♂	130-147	23-26	19-23	90-102 134-168 mm
♀ ♀	130-144	23-26	19-23	93-98 143-157 mm (SA, HW)

Weight 15 ♂ ♀ 40-51 (av. 45.7) g — SA.

All three subspecies go through the same plumage stages as follows:

The juvenile differs from the adult in having,

1. body plumage softer and browner with very little metallic gloss and that confined to the upper plumage,
2. wings and tail shorter and duller with less gloss,

965. Indian Grey Drongo. *Dicrurus leucophaeus longicaudatus* Hay

(*Dicrurus*) *longicaudatus* Lord Arthur Hay, in Jerdon, 1845, Madras Jour. Lit. Sci. 13: 121 nom. nud.

Dicrurus longicaudatus A. Hay, in Horsfield & Moore, 1854, Cat. Bds. Mus. E.I. Co. 1: 152 (Segour Pass, Neilgherries); also A. Hay in Jerdon, 1862, Bds. India 1: 430

Dicrurus leucophaeus minimus Baker, 1918, Novit. Zool. 25: 296 (Ceylon)

Dicrurus leucophaeus beavani Vaurie, 1949, Bull. Amer. Mus. Nat. Hist. 93: 243 (Khudi Khel, eastern Afghanistan)

Baker, FBI No. 775, Vol. 2: 362
Plate 67, fig. 8

LOCAL NAMES. *Neel finga* (Bengali); *Erattāi vālan kūruvi* (Tamil); *Kakkattāmpūrān* (Malayalam); *Gunkots*, *Telakots* (Kashmiri).

SIZE. Same as of Black Drongo: bulbul +. Length c. 30 cm (12 in.).

FIELD CHARACTERS. A slim glossy slate-black drongo with long deeply forked tail and conspicuous crimson eyes. Underparts duller unglossed grey. Sexes alike.

'Slimmer build, relatively longer, deeper-forked tail and better-wooded habitat will help differentiation from Black Drongo of open plains, and ruby-red eye will clinch the diagnosis.

When deep tail-fork absent during moult, could be casually confused in the distance with Black Bulbul (*Hyphantornis madagascariensis*, 1148/9) but which has red bill and legs.

STATUS, DISTRIBUTION and HABITAT. Breeds in the Himalayas in West Pakistan and India (foothills, up to c. 3300 m) from the Afghan frontier (Safed Koh) east through Chitral, Gilgit, Kashmir, Himachal Pradesh, Garhwal, Kumaon, Nepal, Sikkim, northern W. Bengal (Darjeeling dist.), and Bhutan, where it intergrades with *hopwoodi* (966). In winter (September/October to March/April) descends to lower altitudes and spreads out throughout the better-wooded portions of the northern plains and the Peninsula (including non-arid portions of Rajasthan, Kutch and Saurashtra),

118

DICRURIDAE

Tail, × c. 1

3. under wing-coverts edged with white; outer edge of secondaries may also be narrowly edged white.

The postjuvinal moult does not include,

1. primaries, secondaries and tertiaries; primary-, greater-, and sometimes a few median coverts; under wing-coverts,
2. tail.

The first-winter and summer plumage is distinguished from adult plumage by,

1. long upper tail-coverts being usually edged with white,
2. lower plumage less glossy, the feathers from lower breast to under tail-coverts being fringed with white to a variable extent (these gradually wear down and in summer are less noticeable),
3. duller, more faded appearance of the unmoulted parts of the juvenile plumage, and the white edging on the under wing-coverts.

This plumage is retained until the autumn when the first complete moult gives fully adult plumage in the second winter. Adults occasionally have the under tail-coverts edged with white, but never so the upper tail-coverts or the under wing-coverts (Whistler).

COLOURS OF BARE PARTS. As of 962.

964. Ceylon Black Drongo or King Crow. *Dicrurus adsimilis minor* Blyth

Dicrurus minor Blyth, 1854, Cat. Bds. Mus. Asiatic Soc., Pref. app. 3, No. 1219: 22 (Ceylon)

Baker, FBI No. 768, Vol. 2: 358

LOCAL NAMES. *Kāudā* (Sinhala); *Erattāi vālan kūruvi* (Tamil).

SIZE. Bulbul +; length, including longish forked tail, c. 26 cm (11 in.).

FIELD CHARACTERS. As of 962, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Endemic to Ceylon. Common in the low-country Dry zone in the northwest coastal areas from Puttalam to Jaffna Peninsula, occasionally straying in winter to other districts in the Wet and Hill zones (Phillips). Affects openly wooded country.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 962. Notes described as 'loud, ringing and varied, some of them very musical' (Henry). Is a good mimic of other birds' calls.

BREEDING. Season, February to June, chiefly April and May. Nest, eggs (c/2 or 3, rarely 4), and breeding biology as in the Indian subspecies. Average size of 21 eggs 24.2 × 18.1 mm (Baker).

MUSEUM DIAGNOSIS. The smallest of the three Indian forms, with a smaller, weaker bill.

120

DICRURIDAE

east to W. Bengal, south through Tamil Nadu and Kerala. Winter visitor also to Ceylon.

Affects pine, oak and rhododendron forest in the Himalayas; broken, well-wooded country (deciduous as well as evergreen) in its winter range. Mixed bamboo jungle, edge of forest clearings, and shady village groves are favourite haunts. In SW. India coffee and cardamom plantations in shola forest (with tall shade trees), and gardens or 'kampongs' by the backwater homesteads are especially favoured.

Extralimital. Eastern Afghanistan south of the Hindu Kush (Vaurie).

GENERAL HABITS. Very similar to those of Black Drongo (962), q.v. but essentially a forest bird, not found in open cultivated country. Keeps singly, in pairs or small noisy parties, perching high up in tree-tops, launching agile swooping sallies after flying insects close to the ground or in and out amongst the tree-trunks and foliage canopy; sometimes gatherings of 30 or more birds, e.g. at a hatch of winged termites emerging from a nest-mound in forest. Crepuscular; often hunting till almost quite dark.

FOOD. As in Black Drongo, mainly insects — locusts, grasshoppers, crickets, moths, termites, etc.; occasionally butterflies, lizards and small birds (warbler, iora). Bees from a hive (Ingilis). Very fond of flower-nectar, and invariably amongst the most regular visitors to *Salmalia* and *Erythrina* blossoms and to those of the introduced *Grevillea robusta* and various *Eucalyptus* spp.

VOICE and CALLS. A varied assortment of harsh screeches and pleasant musical whistling notes. One common call: a harsh challenging *cheet-cheet-chick* (like the Black Drongo's) followed by a pleasant querulous whistling *kil-kil-kil-kil* (or *tililili*), very like the 'song' of the Striped Squirrel (*Funambulus pennanti*). Another common call rendered as *drāngh-gip, gip-gip-drāngh* (Magrath). Is a good mimic of other birds' calls as well.

BREEDING. Season, chiefly April to June. Nest, a neat shallow saucer of lichens and leaves bound together and secured in position with cobwebs; lined with fine grass. Fixed like a cradle in a horizontal or vertical fork at the end of a slender branch, often 15 to 20 m up, in a pine, oak, chinar, sal or similar tall tree. Eggs, 3 or 4, like those of Black Drongo (962/3) but more variable in ground colour (some rich salmon or deep terracotta) and somewhat more heavily marked. Average size of 200 eggs 23.6 × 18.2 mm (Baker). Both sexes take part in building the nest, incubation, and tending the young. Incubation period undetermined.

MUSEUM DIAGNOSIS. See Key to the Subspecies.

Juvenile plumage differs from adult in two important particulars: (1) body plumage softer and a browner black, practically without any gloss, (2) wings and tail as in adult but considerably shorter. Postjuvinal moult excludes primaries and primary coverts, secondaries and greater coverts, tertiaries, and rectrices. These are retained to the following autumn so that first-winter and first-summer birds differ from adults in their more worn and faded, also shorter, wings and tail. When measuring specimens it is therefore essential that adult and first-year birds also be measured separately to ensure satisfactory comparison. First-year birds also appear to be paler and duller on the abdomen, slight white fringes being more noticeable, especially on under tail-coverts. Complete postnuptial moult evidently takes place between July and September. There is no definite spring moult, though odd body feathers are changed.

DRONGOS

121

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail	
				central	outer
♂♂	136-148	25-28	18-20	89-93	140-187 mm
♀♀	131-144	25-28	18-20	89-96	148-168 mm

Weight 40 ♂♀ (October, in winter quarters) 32-45 (av. 37.6) g (SA).

COLOURS OF BARE PARTS. Iris brownish red, orange-red, or crimson. Bill, legs, feet and claws black. Mouth brownish pink, pale pink, or slaty pink.

966. Assam Grey Drongo. *Dicrurus leucophaeus hopwoodi* Baker

Dicrurus leucophaeus hopwoodi Baker, 1918, Novit. Zool. 25: 294 (Dacca)

Dicrurus leucophaeus stevensi Baker, 1918, Novit. Zool. 25: 295 (Darjeeling)

Baker, FBI No. 773, Vol. 2: 361

LOCAL NAMES. *Nel fings* (Bengali); *Sahim*, *Sahim pha* (Lepcha); *Chu-chum* (Bhutancese).

SIZE. Same as of Black Drongo: bulbul +. Length c. 30 cm (12 in.).

FIELD CHARACTERS. As of 965, q.v. See Key to the Subspecies.

STATUS, DISTRIBUTION and HABITAT. Breeds in the eastern Himalayas in Bhutan (where it intergrades with *longicaudatus*) and NEFA; also Assam hills north and south of Brahmaputra R., Nagaland and Manipur (?) from the edge of the plains to c. 2100 m. In winter spreads south into the plains of West Bengal, Assam and E. Pakistan. Affects well-wooded country, as 965. *Extralimital*. Northern and central Burma and Indochinese countries. (For details see Vaurie, 1959, 2: 122.)

GENERAL HABITS, FOOD, VOICE and CALLS. As in 965.

BREEDING. Season, April to June. *Nest*, eggs (c/3 or 4) and breeding biology as in 965.

MUSEUM DIAGNOSIS. See Key to the Subspecies. Paler above and below than *longicaudatus*; tail averages a little shorter and less deeply forked.

MEASUREMENTS

Dicrurus leucophaeus meridionalis Hachisuka, 1926, Bull. Brit. Orn. Cl. 47: 56

(Seven Finger Range, central Hainan)

Baker, FBI No. 779, Vol. 2: 367 (= *leucophaeus*)

Plate 67, fig. 9

SIZE. Same as of Black Drongo: bulbul +. Length c. 30 cm (12 in.).

FIELD CHARACTERS. As of 965, q.v., but much paler grey. See Museum Diagnosis.

DRONGOS

123

GENERAL HABITS. Typical of the family. Keeps in noisy twos and threes, often in association with roving hunting parties of other insectivorous birds and — wherever the two occur together — very commonly with the Bronzed Drongo. Hawks winged insects from tree-tops oftener like a flycatcher, making short looping sallies after them, turning and twisting in the air, snapping up the quarry in the bill or claws (if of large size), and returning with it to the same or a nearby perch. Is markedly crepuscular, often keeping up the hunt till well after dusk when almost quite dark.

FOOD. Crickets, grasshoppers, moths, winged termites and other insects. Occasionally small birds like warblers, chased and seized in the claws in mid-air. Food often pirated from other birds by dogged pursuit or surprise attack. Flower-nectar, e.g. of *Bombax* and *Erythrina* regularly eaten; doubtlessly promotes cross-pollination.

VOICE and CALLS. Pattern similar to King Crow's, but calls much less harsh. Normally 3 or 4 pleasant whistling notes — one of the commonest bird-calls wherever the drongo present. Has many pleasing whistles, some of rich oriole or thrush quality. 'Often whistles very quietly as if trying the notes over under its breath' (Hewitson). Is an excellent and convincing mimic: imitates, among others, Tailor Bird, Wood Shrike and Iora to perfection, not only the sweet sibilant whistles of the last but also the occasional *chr-r-r* with which they are punctuated.

BREEDING. Season, overall March to June, mostly March and April. *Nest*, not markedly different from that of Black Drongo (962) except as regards the site which is normally in mixed teak and bamboo and similar open forest. Eggs, usually 2 or 3, sometimes 4, more like those of Grey Drongo than of Black. A common type is warm salmon pink in ground colour, blotched and spotted with black or reddish brown. Average size of 40 eggs 23.6 × 17.8 mm (Baker). Both sexes take part in building the nest, incubation and tending the young. Incubation period unrecorded.

MUSEUM DIAGNOSIS. See Key to the Subspecies.

Young (immature) very brown, with traces of white barring on breast, flanks, axillaries and under wing-coverts.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail	
				central	outer
♂♂	122-137	22-25	18-20	85-91	112-130 mm
♀♀	118-129	22-25 (27)	18-21	85-95	113-130 mm

Weight 2 oo? 39, 41 g (SA).

COLOURS OF BARE PARTS. Iris brownish red. Bill black; mouth pale pink, slaty pink or pale pinkish yellow. Legs, feet and claws black.

968. Ceylon Whitebellied Drongo. *Dicrurus caeruleus insularis* (Sharpe)

Buchanga insularis Sharpe, 1877, Cat. Bds. Brit. Mus. 3: 253

(Lunugalla, Madodouna, Ceylon)

Baker, FBI No. 777 (part), Vol. 2: 365

LOCAL NAMES. *Kāndā*, *Kāndā* *amittiya* (Sinhala); *Erattai eḷḷān kūrāri* (Tamil).

SIZE. Bulbul +; length c. 24 cm (9½ in.).

DICRURIDAE

122

STATUS, DISTRIBUTION and HABITAT. Rare vagrant? A specimen collected in Nagaland, 20.i.1936 at Chizami (Khezabama) c. 40 km ESE. of Kohima the only definite record within Indian limits (P. K. Das, 1965, JBNHS 62: 557). Possibly occurs in or visits the Andaman Is. (a specimen of '*leucogenys*' — Hume, 1876, SF 4: 289).

Extralimital. SE. China inland . . . and on the coast south from the Fukien-Kwangtung boundary. Migrates to Hainan, and through the Indo-chinese countries, E. and S. Thailand to the Malay Peninsula as far south as Malacca (Vaurie).

MUSEUM DIAGNOSIS. Adult (♂♀), overall pale French grey; a frontal band and chin blackish; a whitish oval patch on each side of head extending from bill to over ear-coverts. Under wing-coverts whitish at edges and tips of the feathers. Young (immature), slightly darker grey; whitish check-patches less distinct.

MEASUREMENTS

	Wing	Bill (from skull)	Tail		Depth of fork
			central	outer	
♂♂	139-145	23-28	101-108	130-142	29-38 mm
♀♀	137-145	24-28	101-109	129-131	27-30 mm

967. Indian Whitebellied Drongo. *Dicrurus caeruleus caeruleus* (Linnaeus)

Lenius caeruleus Linnaeus, 1758, Syst. Nat., ed. 10, 1: 95 (Benghala)

Baker, FBI No. 777 (part), Vol. 2: 365

Plate 67, fig. 12

LOCAL NAMES. *Pādhāri būchāngā*, *Dhapri* (Hindi); *Dhouli* (Bengal); *Nella* or *Konda pāsāla poligādu* (Telugu).

SIZE. Bulbul +; length c. 24 cm (9½ in.).

FIELD CHARACTERS. A typical drongo with long, deeply forked tail. Glossy indigo colour above, brownish grey below with white belly and under tail-coverts. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Resident, subject to some seasonal local and altitudinal movement. All India south and east of a line roughly from Kutch (Bhuj, Mandvi) to Ambala and Simla, thence eastward through Uttar Pradesh, Nepal, Bihar and W. Bengal. From plains level to c. 2000 m, in dry- and moist-deciduous and bamboo forest. Partial to shady paths and edges of clearings in thin tree jungle, and wooded compounds in inhabited rural areas.

124

DICRURIDAE

FIELD CHARACTERS. As of 967, q.v. See Key to the Subspecies and Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Subspecies endemic to Ceylon. Resident. Common in the low-country Dry zone and Hill zone to at least c. 1500 m. Affects outskirts of forest and well-wooded areas.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 967.

BREEDING. Season, February to June, chiefly March and April. *Nest*, eggs (c/2 or 3) and breeding biology, as in 967. Average size of 75 eggs (together with those of 969) 22.0 × 17.1 mm (Baker).

MUSEUM DIAGNOSIS. Darker (purer black) above than peninsular birds but only slightly so than those from Kerala. White of abdomen reduced: not sharply defined or extending to flanks as in 967. Bill heavier.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail	
				central	outer
8 ♂♂	119-127	25-26	19-20	80-91	104-117 mm

COLOURS OF BARE PARTS. As in 967.

969. Ceylon Whitevented Drongo. *Dicrurus caeruleus leucopygialis* Blyth

Dicrurus leucopygialis Blyth, 1846, Jour. Asiat. Soc. Bengal 15: 298

(Colombo, W.P., Ceylon)

Baker, FBI No. 778, Vol. 2: 366

LOCAL NAMES. Same as for 968 in Sinhala and Tamil.

SIZE. Bulbul +; length c. 23 cm (9½ in.).

FIELD CHARACTERS. As of 967 and 968, qq.v., but dark bellied, the white restricted to vent, under tail-coverts and posterior flanks. Sexes alike.

STATUS, DISTRIBUTION and HABITAT. Subspecies endemic to Ceylon. Resident. Common in the low-country Wet zone and neighbouring lower hills to c. 500 m. Confined to forest and well-wooded areas.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 967 and 968.

BREEDING. Season, February to April, chiefly March. *Nest*, eggs (c/2 or 3) and breeding biology, as in 967.

MUSEUM DIAGNOSIS. See Key to the Subspecies and Field Characters. An ecological form, grading into *insularis* in the drier northern, eastern and southeastern parts of the Island.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail

125

970. Crowbilled Drongo. *Dicrurus annectans* (Hodgson)(Bhuchanga) *Annectans* Hodgson, 1836, Ind. Rev. 1 (8): 326 (Nepal)
Baker, FBI No. 765, Vol. 2: 353

Plate 67, fig. 3

LOCAL NAME. *Kak raja sorai* (Assam).

SIZE. Myna +; length c. 27 cm (10½ in.) to tip of tail.

FIELD CHARACTERS. A glossy jet black drongo very like the familiar King Crow (963) but with larger, heavier bill and shorter, less deeply forked tail. Distinguished also by stockier build and forest habitat (v. open cultivation). Sexes alike.

x c. 1

STATUS, DISTRIBUTION and HABITAT. Resident (or breeding summer visitor?); seasonal movements and migrations unclear. Uttar Pradesh from Kumaon (c. Almora), Nepal (terai and duns), Sikkim (lowlands), N.

Bengal (duars), Bhutan (foothills), Assam north and south of Brahmaputra R., Nagaland, Manipur, East Pakistan (hill tracts); from plains level to c. 700 m. A doubtful record from Nicobar Is., possibly a straggler (1874, Hume,

Dicrurus annectans

Distributional range

SF 2: 209). Affects dense moist-deciduous and evergreen forest; also well-wooded compounds with large trees in this biotope.

Extralimital. N. and C. Burma, N. Thailand. Migrates through Tenasserim, Malay Peninsula and islands, to Sumatra, Java, Borneo.

DRONGOS

127

STATUS, DISTRIBUTION and HABITAT. Resident, moving about locally in winter. Uttar Pradesh (from c. Mussooree) eastward through Nepal, Sikkim, Bhutan, NEFA, Assam (north and south of Brahmaputra R.), Nagaland, Manipur, Mizo (?), East Pakistan; West Bengal and eastern Bihar southward along the Eastern Ghats complex in Orissa, eastern Madhya Pradesh (Bastar dist.), Andhra and Tamil Nadu; east across the Shevaroy Hills

Dicrurus aeneus

Distributional range

D. a. aeneus (971).

to southern Kerala; thence northward along the Sahyadri or Western Ghats strip (including Nilgiri, Palni, and associated hills) to north of Bombay -- probably to the Tapi river, c. 21°N. (unconfirmed sight record, Surat Dangs, February, SA). Up to c. 2000 m in the Himalayas and peninsular hills. Affects broken foothills country for preference, in moist-deciduous and evergreen forest biotope. Keeps to wooded glades, the edge of forest paths, firelines and clearings, mixed bamboo jungle, tea, coffee and rubber plantations; in Kerala the fruit gardens or 'kampongs' around the back-water homesteads are favourite resorts.

Extralimital. Burma, Yunnan, Thailand, Indochinese countries, Malay Peninsula south to c. 4°N. whereabouts it intergrades with *malayensis*.

GENERAL HABITS. Forest-haunting and strictly arboreal. Keeps singly or in pairs to wooded shady glades with dense undergrowth, often near water; hardly ever ventures out in the open. Very parochial and territorial, frequenting the same spot day after day, and winter after winter. Commonly associates with the mixed foraging parties of insectivorous birds in forest. Hawks very much in the manner of a flycatcher, making short sprightly aerial sallies, often swooping close to the ground to snatch a winged insect and looping back to the same perch. Also makes vertical sorties of a metre or two from tree-tops, diving back to the perch with wings closed after each

126

DICRURIDAE

GENERAL HABITS. A comparatively low-elevation forest drongo, not uncommon seasonally in the appropriate habitats of its range. Keeps to tall undergrowth and lower parts of the foliage canopy rather than to exposed tree-tops. Little specifically recorded. Close superficial similarity to and possible confusion with Black and Bronzed drongos vitiates the reliability of casual field observations.

FOOD. Crickets, grasshoppers, hemipterous bugs, flying termites, and other insects; doubtless also other small living creatures.

VOICE and CALLS. Described as similar to those of Black Drongo but 'peculiarly clear and loud' (A. E. Osmaston), 'pleasanter and more musical' (BB).

BREEDING. Season, April to June. Nest, a small fragile-looking shallow cup of grasses, rootlets, fibres, etc. bound together with cobwebs, reminiscent of nest of cuckoo-shrike or minivet; cradled in a horizontal fork of a slender branch c. 5 to 12 metres up, in heavy forest; occasionally in scrub jungle. Eggs, 3 or 4, variable; usually pale cream to warm salmon or salmon-buff, longitudinally streaked (rather than spotted) with red-brown or purple-brown, with underlying streaks of pale grey or lavender, the markings more numerous at the broad end. Average size of 100 eggs 26.3 x 19.4 mm (Baker). Both sexes take part in building the nest, but *sic* Baker only the female incubates. Incubation period undetermined.

MUSEUM DIAGNOSIS. Whole plumage glossed with steel-blue. Under wing-coverts dull black with a round white spot at tip of each feather. Tail-fork shallow; outer rectrices curving outward.

First-year birds spotted with white from throat downwards, the spots becoming broad white tips on belly and under tail-coverts; flanks ashy grey.

MEASUREMENTS

	Wing	Bill (from skull)	Tail central	outer	Depth of fork
♂♂	140-150	28-32	99-107	119-134	18-26 mm
♀♀	137-147	28-30	100-112	120-130	15-28 mm (Vaurie)

Weight 1 ♀ 44 g (SDR).

COLOURS OF BARE PARTS. Iris hazel or deep brown to lake red. Bill, legs, feet and claws black.

971. Bronzed Drongo. *Dicrurus aeneus aeneus* Vieillot*Dicrurus aeneus* Vieillot, 1817, Nouv. Dict. d'Hist. Nat. 9: 586

(Bengal, restricted to Dacca by Baker, 1924, Fauna Br. India, Birds 2: 368)

Baker, FBI No. 780, 781, Vol. 2: 368, 369

Plate 67, fig. 6

LOCAL NAMES. *Chhota bhūjāngā* (Bengal); *Chhota kārāj* (Hindi, Gorakhpur); *Chaptia* (Nepal); *Chinna kārī kūrūni* (Tamil); *Lālitakaka* (Malayalam).

SIZE. Bulbul +; length c. 24 cm (9½ in.) including longish forked tail.

FIELD CHARACTERS. A small black forest drongo, highly glossed all over with bronze-green and blue. Superficially like the familiar Black Drongo or King Crow but appreciably smaller, more iridescent, and with less deeply forked tail. Bill broad and flattened like flycatcher's. Sexes alike.

DICRURIDAE

128

capture. Is characteristically bold and pugnacious and will attack and put to rout crows and even raptors intruding within the precincts of its nest-tree.

FOOD. Winged insects: midges, flies, ants, moths (Diptera, Hymenoptera, Lepidoptera), etc.; also flower-nectar.

VOICE and CALLS. Noisy and demonstrative during breeding season, comparatively silent otherwise. Has a wide repertoire of loud clear musical whistles interwoven with excellent and faithful mimicry of other birds' calls.

BREEDING. Season, overall March to June. Nest, a shallow cup of fragments of inner bark of trees, strips of banana leaf, grasses, etc. felted and cemented together and fixed into the site with vegetable fibres and cobwebs; copiously plastered on the outside with the latter until nearly white in colour, but usually very inconspicuous. Size of nest approximately 10 cm (outside diameter); cup c. 7 cm across x 4 cm deep inside; suspended like a hammock in a horizontal fork in terminal twigs of a leafless lateral branch of a teak sapling or similar small tree; sometimes near the tip of a curving bamboo stem. Eggs, 3 or 4, variable; most common type pale pinkish fawn to pale salmon-pink with an irregular zone of darker cloudy spots, in some cases reddish or purplish, round the broad end. Size of eggs c. 21 x 16 mm. Both sexes take part in building the nest, incubation, and rearing the young. Incubation period undetermined.

MUSEUM DIAGNOSIS. Differs from extralimital *malayensis* (with which South Indian birds were placed by Baker) in being larger, with the rump generally lighter coloured (often grey) and without gloss; abdomen, vent and under tail-coverts also more grey.

MEASUREMENTS

	Wing	Bill (from skull)	Tail central	outer	Depth of fork
♂♂	112-131	20-25	78-93	105-131	19-39 mm
♀♀	112-127	21-25	80-92	105-124	19-36 mm (Vaurie)

Tarsus 15-17 mm (SA)

Weight 5 ♂♂ 26-28; 2 ♀♀ 22, 30 g (SDR, GD, BB).

COLOURS OF BARE PARTS. Iris brown to reddish brown or crimson. Bill black; mouth greyish pink or slaty pink. Legs, feet and claws black.

972. Lesser Racket-tailed Drongo. *Dicrurus semifer lectirostris* (Hodgson)(Bhringa) *Tectirostris* Hodgson, 1836, Ind. Rev. 1 (8): 325 (Nepal)

Baker, FBI No. 786, Vol. 2: 375

Plate 67, fig. 2

LOCAL NAMES. *Chhōis bhīmāj* (Bengal, Assam); *Namsong punnong* (Lepcha); *Poyadiyapo* (Bhutanese); *Das raja kashiba* (Chachari).

DRONGOS

129

SIZE. Myna +; length c. 28 cm (11 in.), plus c. 9 cm to end of tail-rackets. FIELD CHARACTERS. A glossy metallic black forest drongo with a velvety pad-like tuft of feathers above base of bill; two curiously elongated wire-like outer tail-feathers ending in spatulae or 'rackets', fully webbed on both sides of shaft (contra 976, q.v.). Sexes alike.

In the flying bird these rackets, undulating behind, look singularly like a pair of angry bumble-bees in hot pursuit!

STATUS, DISTRIBUTION and HABITAT. Resident. The lower

Himalayas from Garhwal (Tons Valley, c. 78°E.) eastward through Kumaon, Nepal, Sikkim, N. Bengal (Darjeeling dist.), Bhutan and NEFA. Assam north and south of Brahmaputra R., Nagaland, Manipur, Mizo. East Pakistan

Dicrurus remifer

■ Distributional range

D. r. tectirostris (972).

(hill tracts); from the edge of the plains, through the foothills up to c. 2000 m. Affects heavy moist-deciduous and evergreen forest.

Extralimital. Burma south to c. 16°N. lat., Yunnan, N. Thailand and the Indochinese countries. Other races in Cambodia, Malay Peninsula, Sumatra, Java.

GENERAL HABITS. Entirely arboreal. Keeps singly or in twos and threes to tree-tops or high up within dense foliage canopy in heavy jungle. Frequents shady glades and edge of openings, firelines or forest streams. Hawks winged insects usually in the manner of a flycatcher, making

130

DICRURIDAE

Tail, x c. 1

short looping sallies, often swooping close to the ground, and returning to the same or a nearby perch. Is regularly met in association with the itinerant mixed hunting parties of flycatchers, laughing thrushes and assorted insectivorous forest birds, often side by side with its larger racket-tailed congener (976), which has very similar habits. Flight dipping and noisy.

FOOD. Chiefly insects; also flower-nectar.

VOICE and CALLS. A wide range of loud metallic musical whistles not readily distinguishable from those of Large Racket-tailed Drongo; like it, also an excellent mimic of other birds' calls.

BREEDING. Season, April to June. Nest, a shallow cup of roots, grass stems, wiry tendrils, etc. rather loosely bound together with cobwebs and secured with the same hammockwise in a horizontal fork of twigs near the extremity of a lateral branch; sometimes high up in a large tree but usually under c. 7 metres from the ground; occasionally low down in the fork of a bamboo almost within hand reach. Eggs, 3 or 4, variable in ground colour from pale pink to rich salmon-pink or terracotta, blotched and freckled with darker terracotta or purplish brown, more densely at the broad end. Average size of 100 eggs 25.5 x 18.4 mm (Baker). Both sexes take part in building the nest, incubation and rearing the young. Incubation period undetermined.

Brood-parasitism by Drongo-Cuckoo (*Surniculus lugubris*, 588) reported (Hopwood & McKenzie, JBNHS 25: 89).

MUSEUM DIAGNOSIS. Young (immature). Duller, less glossy above, greyer on abdomen, with the white tips to axillaries and under wing-coverts larger than in adult. Lacks frontal tuft and tail-rackets. Tail normal shaped (i.e. without bare shafts) and slightly forked.

For description of succession of 1st-year, 2nd-year and 3rd-year (adult) plumages see Vaurie, 1949: 271.

MEASUREMENTS

	Wing	Bill (from skull)	Tail central outer	Bare shaft
♂♂	137-149	25-30	117-129 402-532	182-306 mm
♀♀	133-146	24-28	116-126 354-466	137-241 mm

Tarsus 21-22 mm (SA)

Weight 4 ♂♂ 48-51 g (BB); 1 ♀ 46 g (SA).

COLOURS OF BARE PARTS. Iris brown to brownish crimson. Bill, legs, feet and claws black.

Dicrurus hottentottus

■ Distributional range

D. h. hottentottus (973).

132

DICRURIDAE

STATUS, DISTRIBUTION and HABITAT. Resident, subject to seasonal movements and wanderings governed largely by availability of its staple diet of flower-nectar. The Himalayan foothills and submontane tract from Kalka hills (c. 77°E.) eastward through Uttar Pradesh, Nepal, Sikkim, N. Bengal, Bhutan and NEFA. Assam north and south of Brahmaputra R., Nagaland, Manipur, Mizo (?), East Pakistan (hill tracts), W. Bengal, eastern Bihar,

southward along the E. Ghats complex in Orissa, eastern Madhya Pradesh (Bastar and Balaghat dists.), Andhra and Tamil Nadu. Kerala, western Mysore (Malnaad), and northward, along the Sahyadri or W. Ghats strip at least to Bombay straggling irregularly to Kutch (c. 22°50'N.) — Him-matsinjhi, JBNHS 60: 734. From plains level to c. 1400 m; occasionally to 2000 m. Affects moist-deciduous and evergreen forest biotope.

Distribution and ecology more or less overlap those of *Dicrurus aeneus* (971), q.v.

Extralimital. Burma, Thailand, Indochinese countries. Numerous other races extend the species over China, Philippines, and across to New Guinea and Australia.

GENERAL HABITS. Forest-haunting and entirely arboreal. Predominantly a nectar-feeder, the long and pointed downcurved

bill, markedly different from other drongos, evidently an adaptation for this diet (structure of tongue needs proper study).¹ Keeps to dense jungle and wooded glades, singly or in small parties; occasionally gatherings of up to 20 or more, e.g. when mobbing a predator or to feed in a grove of flowering trees (once 'a flock of 40 to 50 bathing' — Hopwood). Is a regular member of the roving bands of assorted insectivorous birds in forest, and invariably in attendance on flowering Silk Cotton (simul) trees in clearings. Adopts 'dog-in-the-manger' tactics when feeding from the blossoms, swooping without provocation upon other visitors in the same quest and bullying them off even from distant branches or adjacent trees. Has a noisy flight with thudding wing-beats. Numbers have been observed bathing by repeatedly dashing into water from an overhanging tree (Hopwood, JBNHS 21: 1201).

FOOD. Principally flower-nectar; also insects. *Salralia risalabaria*, *Bombax insignis*, *Erythrina indica*, *E. stricta*, *E. lithosperma*, *Acrocarpus* sp. some of the most commonly patronized species; also various introduced *Eucalyptus* species. From the thick coating of pollen always present on the bird's forehead and throat feathers, is evidently instrumental in promoting cross-pollination.

VOICE and CALLS. A subdued metallic clanging note constantly uttered; also creaking calls reminiscent of the sharp *teei?* notes of Blossom-headed

¹ According to Beecher shows marked nectar-feeding adaptations (Beecher, W. J., 1953. Phylogeny of the Oecinae. *Auk* 70: 270-333).

DRONGOS

133

Parakeet (*Psittacula cyanocephala*, 558). Very noisy in breeding season: loud clear whistles and mimicry of other birds' calls.

BREEDING. Season, April to June in N. India; March–April in the south. Nest, of the usual drongo pattern, a deep saucer of pieces of bark, grass, rootlets, and tendrils of creepers, etc., often rather loose and untidy, and lacking the cobweb plastering on the exterior: measuring 9–10 cm across (inside) and 4–5 cm deep; sides about 10 mm thick but bottom so flimsy that the contents usually visible from below. Built in a horizontal fork of twigs near the extremity of a lateral branch, usually between 5 and 10 metres up, but sometimes almost within hand reach from the ground; occasionally in the head of a *Borassus* or other palm at the base of the leaf stalks. Eggs, 3 or 4, variable in coloration and markings: commonly creamy to salmon pink, minutely freckled with light red or purplish red. Average size of 200 eggs 29.2 × 21.2 mm (Baker). Both sexes take part in building the nest, incubation, and tending the young. Incubation period unrecorded.

MUSEUM DIAGNOSIS. Neck and breast feathers hackle-shaped, brightly glossed and spangled. Tail with the four inner pairs of rectrices of equal length; outer pair a little longer, twisted round and curling upward near tip.

Young (immature) browner and with less metallic gloss; hackle feathers of neck and breast, and forehead filaments, shorter. Axillaries and under wing-coverts tipped with white.

Nestling. 'Brown with obsolete white bars to the abdomen, flanks and breast; bold white tips to the axillaries and under wing-coverts and pale edges to the wing-coverts' (Baker).

MEASUREMENTS

Peninsular birds

	Wing	Bill (from skull)	Tail central	Tail outer
♂♂	160–172	26–30	117–135	132–155 mm
♀♀	154–166	25–29	120–133	131–149 mm

(Vaurie)

Tarsus 26–29 mm (SA)

There is a cline of increasing size from south to north. Birds from the Punjab Himalayas to eastern Assam are larger than from south India. Vaurie and some other authors therefore prefer to retain these under the subspecies *chirishna* Gould. Vaurie measures northern birds as follows:

	Wing	Bill (from skull)	Tail central	Tail outer
♂♂	168–180	28–31	126–134	149–164 mm
♀♀	165–183	28–30	131–143	144–163 mm

Weight 4 ♂♂ 86–102; 2 ♀♀ 76, 90 g (GD, SA, BB).

COLOURS OF BARE PARTS. Iris reddish brown or dark brown. Bill, legs, feet and claws black.

DICRURUS ANDAMANENSIS Tytler

Key to the Subspecies

Smaller *D. a. andamanensis*

DRONGOS

135

company with *Irena puella*; *Sturnus erythropygius*, *Coracina striata*, *Pericocelus cinnamomeus*, etc.' (Butler, JBNHS 12: 291). Frequently observed clinging to tree-trunks like a woodpecker, pressing the tail against the bark and ascending in flitting hops.

FOOD. Mainly winged insects hawked in the air.

VOICE AND CALLS. A variety of sharp metallic notes, typical of the drongos. Slightly jerks up tail after each note. 'A long tseep' (HA).

BREEDING. Season, April and May. Nest, a shallow cup of fine dry twigs firmly woven together, bound and suspended with cobwebs cradle-wise in a fork of twigs generally at a considerable height in some dry or leafless tree: scantily lined with black hair-like rhizomorphs. Eggs, 2 or 3, variable; commonest type pale salmon-pink spotted all over with pale brownish markings, with some underlying spots of pale grey (Osmaston). Average size of 50 eggs 24.8 × 18.3 mm (Baker).

MUSEUM DIAGNOSIS. Feathers of crown, hindneck and whole back glossy only at tips and edges, producing a somewhat scaly appearance. Tail long, deeply forked, the outer feathers curving markedly upward. Four inner pairs of rectrices each increasingly longer than its neighbour, *contra hottenottus* where they are all of about equal length.

Differs from *dicuriformis* (974) only in being smaller.

134

DICRURIDAE

974. Large Andaman Drongo. *Dicrurus andamanensis dicuriformis* (Hume)

Dissemuroides dicuriformis Hume, 1873, Stray Feathers 1: 408
(Great Cocos and Table Island)
Baker, FBI No. 784, Vol. 2: 372

LOCAL NAMES. None recorded.

SIZE. Myna ±, with longer tail; overall length c. 35 cm (c. 14 in.).

FIELD CHARACTERS. As of 975, q.v. See Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Endemic in the North Andaman group of islands. Recorded from Great Coco and Table Island. Affects forested areas, 'principally the jungle immediately within the belt of coconut palms that surround the coast' (Hume, SF 2: 211).

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 975, q.v.

BREEDING. Not specifically recorded; doubtless as in 975.

MUSEUM DIAGNOSIS. Differs from *andamanensis* only in being larger.

There is apparently a cline of increasing size from south to north, birds from the Middle Andamans probably intermediate between this form and *andamanensis* (975) as suggested by Abdulali (JBNHS 61: 550). More material needed.

LOCAL NAMES. *Bhimrāj*, *Bhringrāj* (Hindi, Bengali); *Kājia* (Nepal); *Parak* or *Parak pho* (Lepcha); *Dao raja gashim* (Cachari).

SIZE. Myna; with a tail c. 35 cm (14 in.) long.

FIELD CHARACTERS. A large metallic black drongo with a conspicuous backward-curving tuft or crest on forehead, and two long wire-like spatula-tipped streamers in tail. Sexes alike.

× c. 1

STATUS, DISTRIBUTION AND HABITAT. Resident. The lower Himalayas and submontane country from Kumaon eastward through Nepal, Sikkim, Bhutan and NEFA; Assam, Nagaland, Manipur, Mizo; East Pakistan (hill tracts). Northern India roughly east of a line from Pilibhit in Kumaon (c. 80°E.) to Surat in Gujarat (c. 21°N.) thence southeast to Rajahmundry (c. 80°E.) around its southern boundary. From plains level to c. 1500 m. Affects deciduous and evergreen forest biotope: especially well-wooded, broken foothills country. Cultivation edges, tea-gardens, sal, teak and bamboo jungle particularly favoured. Occasionally wanders to jungle patches isolated by several kilometres of cultivation and open treeless country.

EXTRALIMITAL. N. Burma south to Chin Hills and N. Shan States, Yunnan and northern and central Vietnam. Other subspecies in S. Burma, Malay Peninsula, etc.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 977, q.v.

BREEDING. Season, April to June. Nest, eggs (c/3 or 4) and breeding biology as in the peninsular bird (977).

MUSEUM DIAGNOSIS. Feathers at sides and hind part of neck long, pointed and hackle-shaped, forming a prominent cape. Crest very large and full, with the front feathers longer and more attenuated and erect than in South Indian and Ceylonese birds: main feathers of crest also broader, longer, and curving back over the entire crown.

COLOURS OF BARE PARTS. Iris brown to reddish brown. Bill black; mouth pale greyish pink, sometimes mottled with brown, yellow and slate. Legs, feet and claws black.

977. Southern Large Racket-tailed Drongo. *Dicrurus paradiseus paradiseus* (Linnaeus)

Cuculus paradiseus Linnaeus, 1766, Syst. Nat., ed. 12, 1: 172 (Siam, restricted to 'the region between Ayuthia and the head of the Gulf' by Kloss, 1919, Jour. nat. Hist. Soc. Siam 3: 453)

Lenius malabaricus Latham, 1790, Index Orn. 1: 66 (Malabar)

Baker, FBI No. 792, Vol. 2: 381

LOCAL NAMES. *Bhimraj*, *Bhānraj* (Hindi); *Tinka pāṣṭālā poligādu* (Telugu); *Hati* (Gond); *Pellāpūṇṇā kōṇcāl* (Marathi); *Erattai rālān*, *Kondai kārīchān* (Tamil).

SIZE. Myna; with a tail c. 35 cm (14 in.) long.

FIELD CHARACTERS. As of 976, q.v. See Key to the Subspecies and Museum Diagnosis.

Tail, x c. 1/2

off, the end rackets looking singularly like a pair of irate bumble-bees in hot pursuit. Distinctly crepuscular, commonly hunting till far into the dusk, springing up vertically from a tree-top to snatch an insect and diving back to the perch with wings closed.

FOOD. Termites, moths, beetles, dragonflies, locusts, mantises and other insects up to the largest size, hawked in the air; larvae picked off tree-trunks and branches in agile swoops and carried away in claws. Very probably also takes lizards and small birds as other drongos. Flower-nectar

DRONGOS

139

of *Salmaia malabarica*, *Bombax insignis*, *Erythrina* (*indica*, *stricta*, *lithosperma* and other species) an important supplementary diet.

VOICE AND CALLS. Very noisy, especially in the early mornings and at sunset, more so towards the breeding season. Has a large repertoire of loud metallic calls and rich melodious notes and whistling. Is, in addition, an exceptionally versatile and convincing mimic. In the wild state has been recorded mimicking both calls and complete songs (with all their nuances) of the following birds: shikra, serpent eagle, crested hawk-eagle, grey junglecock, barred owl, Indian cuckoo, koel, black woodpecker (*Dryocopus*), goldenbacked woodpecker (*Dinopium*), rufous woodpecker (*Micropternus*), grey hornbill, pitta, jungle babbler, scimitar babbler, oriole, magpie robin, shama. The imitations are sometimes echoed back promptly after the original call and repeated after each, the mimic seeming to mock the producer while obviously enjoying the joke and his own cleverness! Once observed reproducing agitated calls of jungle babbler (*Turdoides striatus*) with the body feathers fluffed out, wings drooping, tail depressed, and pivoting from side to side, 'in exact mimicry of the behaviour of the babbler while thus calling' (Daniel, JBNHS 63: 443). Many intriguing and unexpected bird-calls in forest — also of squirrels (*Ratufa*, *Funambulus*) — may, often be traced down to a single sportive Racket-tail, a fact which stresses the importance of visual evidence in support of 'diagnostic' calls in drongo-ridden areas. In captivity has been recorded imitating song of canary to perfection; also mewing of cat, and 'two or three lines of whistled song with remarkable accuracy' (Finn, JBNHS 14: 568).

BREEDING. Season, chiefly February-May in Kerala; June-July in the northern parts of its range. Nest, a deepish loosely built cup of fine twigs, grasses, tendrils, strips of inner bark, etc. Size: external diameter c. 15 cm, inner cup c. 10 cm across and 5 cm deep. Unlined, and usually with little or no cementing or plastering cobwebs; thus contents of nest often visible through the flimsy bottom from below. Fixed in a horizontal fork of branches (leafy or bare) near the end of a lateral bough in open forest, between c. 5 and 15 m from ground. In some areas the channel-shaped bases of leaf-stalks of *Borassus* palms provide favourite nest-sites. Nests often found in identical patch of forest, even the same tree, year after year; occasionally built of thicker sticks and flatter, like a miniature crow's nest. Eggs, normally 3, rarely 4, somewhat variable. A common type is creamy white or pale pink, blotched and speckled with dark reddish brown, with secondary markings of pale- or pinkish grey. Average size of 40 eggs 27.8 × 20.2 mm (Baker). Both sexes take part in building the nest, incubation, and tending the young. Incubation period undetermined.

MUSEUM DIAGNOSIS. Smaller than northern *grandis* (976) and with shorter crest, the longest feathers reaching to hindcrown.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail central	outer (to tip of racket)
♂♂	151-170	33-37	26-28	133-142	295-484 mm
♀♀	148-154	33-36	26-27	128-136	310-358 mm (SA, HW)

140

DICRURIDAE

Weight 3 ♂♂ 74-85 g (SA).

COLOURS OF BARE PARTS. As in 976.

978. Ceylon Large Racket-tailed Drongo. *Dicrurus paradiseus ceylonicus* Vaurie

Dicrurus paradiseus ceylonicus Vaurie, 1949, Bull. Amer. Mus. Nat. Hist. 93: 329, new name for *Dissemurus ceylonensis* Sharpe, 1877, Cat. Bds. Brit. Mus. 3: 264 (NE. Province, Ceylon), preoccupied by *Dicrurus ceylonensis* Stephens, 1826 Baker, FBI No. 793, Vol. 2: 381

LOCAL NAMES. *Māhā kāudā*, *Kaputā bālaya* (Sinhala); *Erattai rāl kūrūci* (Tamil).

SIZE. Myna; with a tail c. 31 cm (12 in.) long.

FIELD CHARACTERS. As of 976, q.v. See Key to the Subspecies and Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Subspecies endemic in Ceylon. Confined to, and moderately plentiful in the Dry zone in the northern, eastern and southeastern portions of the Island, to c. 600 m alt. Affects tall jungle especially around irrigation tanks and along river banks (Phillips, Henry). Intergrades with *D. p. lophorhinus* (979) along the edge of the Dry and Wet zones.

BREEDING. Season, March to May. Nest, eggs (c/2-4) and breeding biology as in 977.

MUSEUM DIAGNOSIS. Differs from nominate *paradiseus* of peninsular India in being smaller with a less developed crest, the feathers reaching only to top of crown; racket feathers of tail much shorter.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail central	outer (to tip of racket)
7 ♂♂	145-159	31-35	24	121	260-350 mm
2 ♀♀	150, 150	32, 35	25	130, 133	284, 288 mm (HW)

Weight 1 ♂ 71; 1 ♀ 73 g (SDR).

COLOURS OF BARE PARTS. As in 976 and other races.

979. Ceylon Crested Black Drongo. *Dicrurus paradiseus lophorhinus* Vieillot¹

Dicrurus lophorhinus Vieillot, 1817, Nouv. Dict. d'Hist. Nat. 9: 587 (Africa, restricted to Ceylon)

Baker, FBI No. 785, Vol. 2: 373

Plate 67, fig. 5

LOCAL NAMES. *Māhā kāudā*, *Kaputā bālaya* (Sinhala); *Erattai rāl kūrūci* (Tamil).

SIZE. Myna; with longer tail. Overall length c. 35 cm (14 in.).

¹For a discussion of the two ecological forms in Ceylon see Ripley, S. D., 1946, *Sp. Zool.* 24: 218-20, and Vaurie, C., 1949, *Bull. Amer. Mus. Nat. Hist.* 93: 330-1.

DRONGOS

141

FIELD CHARACTERS. As of 977 and 978, qq.v.; also glossy black with

a tuft of feathers at forehead but lacking the racket-feathers in the tail which is merely long and deeply forked. Sexes alike. See Museum Diagnosis.

STATUS, DISTRIBUTION and HABITAT. Subspecies endemic in Ceylon. Confined to, and moderately plentiful in the Wet zone and lower hills, but ascending Adam's Peak to at least c. 1700 m (Henry). Affects tall humid forest in the southwest portion of the Island. Its range is becoming constricted owing to increasing encroachment upon its forest habitat for rubber plantation etc.

Intergrades with *D. p. ceylonicus* (978) along the edge of the Wet and Dry zones.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 977 and the Ceylon Racket-tailed Drongo of the Dry zone (978).

BREEDING. Season, April and May, but very little known. The only authentic nest so far is described as a flimsy cup rather small for the size of the bird, about 10 m up in a tall straight tree on the edge of jungle bordering a paddy field. It contained nestlings on 24th May (Henry). Eggs not authentically described; evidently more or less as in the other racket-tailed drongos, cf. 977.

MUSEUM DIAGNOSIS. Outer feathers of long, deeply forked tail much prolonged beyond the others: webbed on both vanes throughout their length, and strongly upcurved at the tips. Crest shorter, denser and stiffer, the longest feathers curving backward only over the forehead.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail central	outer (to tip of racket)
3 ♂♂	151-155	33-36	—	129-131	185-199 mm
1 ♀	145	34	24	124	170 mm
					(HW)
4 ♂♂	139-146	27-31	—	126-129	moult ¹ mm
4 ♀♀	141-147	28-30	—	119-125	moult mm
					(SDR)

¹ Only one feather in one of the specimens measuring 196 mm.

SWALLOW-SHRIKES

143

GENERAL HABITS, FOOD, VOICE and CALLS. As in the Indian forms 976, 977.

BREEDING. Almost unknown. A nest with sitting bird observed by Humayun Abdulali at end February c. 25 m up in a bare tree in forest.

MUSEUM DIAGNOSIS. 'Differs from *otiosus* of the Andamans by being smaller and by having a crest. Similar to *paradisus* [of peninsular India] and may be separable from it only by the size of the racket which appears to be smaller' (Vaurie).

MEASUREMENTS (of Great Nicobar birds)

	Wing	Bill (from skull)	Tail central	outer (to tip of racket)
2 ♂♂	155, 155	35, 36	127, 131	308, 310 mm
4 ♂♂	150-156	—	—	294-357 mm
				(Vaurie)
				(3 msd.)
3 ♀♀	147-155	—	—	308-322 mm
				(Abdulali)

Birds from Little Nicobar and Katchall (to the north) are larger than from Great Nicobar, tending to agree in size with *otiosus* of the Andamans.

COLOURS OF BARE PARTS. As in *otiosus* and other subspecies.

Family ARTAMIDAE: Swallow-Shrikes or Wood Swallows

For description see Van Tyne, J. & Berger, A. J., 1959: 532; Baker, E. C. Stuart, 1924, FBI 2: 348; Smythies, B. E., 1964. Article 'Wood-Swallow' in Thomson, A. L. (ed.), *New Dict. Birds*. London & New York.

Genus ARTAMUS Vieillot

Artamus Vieillot, 1816, Anal. nouv. Orn.: 41. Type, by monotypy,
Leucorhynchus Linnaeus

Bill strong and gently curved, but not notched or hooked as in the true shrikes (*Leucorhynchus*). Wings long and pointed: first primary (as.) very short; 2nd and 3rd subequal and longest. Tarsi very short. Tail short and square.

Key to the Species

Rump of same colour as back.....*A. fuscus*
Rump white, different from back.....*A. leucorhynchus*

982. Ashy Swallow-Shrike. *Artamus fuscus* Vieillot

Artamus fuscus Vieillot, 1817, Nouv. Dict. d'Hist. Nat. 17: 297
(Bengal)

Baker, FBI No. 763, Vol. 2: 348
Plate 65, fig. 18

LOCAL NAMES. — *Tādi ābābel* (Hindi); *Tāl charai*, *Chātdāk-ānjānd* (Bengal); *Tād pītā* (Telugu); *Mūra sing* (E. Pakistan); *Silliangrechi pho* (Lepcha); *Tāl gas kurullā* (Sinhala); *Mādām parā* (Tamil); *Endakāttārān* (Malayalam).

SIZE. Bulbul ±; dumper with short tail. Length c. 19 cm (7½ in.).

DICRURIDAE

142

Weight 1 ♂ 70; 1 ♀ 70 g (SDR).

COLOURS OF BARE PARTS. Iris brown. Bill, legs, feet and claws black.

980. Andaman Racket-tailed Drongo. *Dicrurus paradisus otiosus* (Richmond)

Dissemurus malabaricus otiosus Richmond, 1903, Proc. U.S. Nat. Mus. 25: 290
(Andamans)

Baker, FBI No. 790, Vol. 2: 380

LOCAL NAMES. None recorded.

SIZE. Myna; with a tail c. 35 cm (14 in.) long.

FIELD CHARACTERS. As of 977 q.v., also with rackets in tail but lacking the frontal crest! See Key to the Subspecies.

STATUS, DISTRIBUTION and HABITAT. Endemic in the Andaman Archipelago: recorded from the North, Middle, South, and Little Andaman groups. Fairly abundant in forested areas.

GENERAL HABITS, FOOD, VOICE and CALLS. As in the Indian forms 976, 977.

BREEDING. Season, May; 'building its nest generally high up on the more or less inaccessible branches of big trees. Eggs, similar to those found in India' (Osmaston, JBNHS 17: 157).

MUSEUM DIAGNOSIS. See Field Characters and Key to the Subspecies.

MEASUREMENTS

	Wing	Bill (from skull)	Tail central	outer (to tip of racket)
♂♂	162-169	34-37	139-152	359-474 mm
1 ♀	157	34	139	330 mm
				(Vaurie)

COLOURS OF BARE PARTS. As in 977 and other subspecies.

981. Nicobar Racket-tailed Drongo. *Dicrurus paradisus nicobariensis* (Baker)

Dissemurus paradisus nicobariensis Baker, 1918, Novit. Zool. 25: 302
(Kondel, Nicobars)

Baker, FBI No. 791, Vol. 2: 380

LOCAL NAMES. None recorded.

SIZE. Myna; with a tail c. 33 cm (13 in.) long.

FIELD CHARACTERS. As of 977, q.v. Very similar to the Andaman bird but somewhat smaller and with a short frontal crest.

STATUS, DISTRIBUTION and HABITAT. Endemic in the Nicobar Archipelago (south of Ten Degree Channel): specifically recorded from Car Nicobar (sight, HA), Katchall, Little Nicobar and Great Nicobar islands. Affects forested areas.

ARTAMIDAE

144

FIELD CHARACTERS. A dark slaty grey short-tailed bird with paler rump and underparts. Tail slaty black tipped with white. Bill bluish, heavy, somewhat finch-like. Sexes alike.

At rest tips of closed wings reach end of tail.

STATUS, DISTRIBUTION and HABITAT. Resident and marked seasonal local migrant, especially in the hills and in heavy-rainfall areas. East and south of

line from about Godhra in Gujarat (c. 23°N., 74°E.) to Simla in Himachal Pradesh (c. 31°N., 77°E.) thence eastward along the Himalayan terai and foothills through Nepal, Sikkim, Bhutan, and NEFA, locally up to c. 1700 m. Throughout peninsular India south to Kerala (common but patchy and local; rare in Madhya Pradesh), from plains level to 1700 m; once over 2100 m (Kodaikanal — Bates); Assam, Nagaland, Manipur and East Pakistan. Widely distributed also in Ceylon: lowlands, lower hills and up to c. 1200 m. Affects openly wooded dry- and moist-deciduous country, especially with a predominance of palms — palmyra, coconut, date, Fish-tail (*Caryota urens*) and other species. Its close association with palms needs study.

Extralimital. Burma, Thailand, the Indochinese countries, and W. China.

GENERAL HABITS. Gregarious and sociable. Keeps in parties or loose flocks, sometimes of 30 or more birds. Usually seen huddled closely together along a horizontal bare branch near a tree-top, leaf-stalks of palms, or telegraph and power wires in open foothills country, old forest clearings, etc. While perched, the stumpy tail is bobbed slowly and deliberately up and down or opened and screwed from side to side. Makes constant sallies after winged insects from such vantage points, one or two birds at a time or several together, sometimes swooping close to the ground to seize the quarry. Not recorded actually settling on ground, but may do so (cf. 983). Flight swift — several rapid wing-beats followed by a graceful effortless glide, reminiscent of a swallow or bee-eater — the bird sailing back to its perch in a wide circle after each capture. Brakes by sudden uptilt of body at last moment accompanied by a spreading of tail and vigorous flutter of wings assuming statue-like immobility immediately on alighting. Quarry frequently transferred to feet in mid-air, torn to pieces with bill, and swallowed in flight. When 'business is brisk', e.g. as at a swarming of butterflies or winged termites, the first victim is promptly transferred to the feet to free the bill for the second, the bird then sailing round to its perch to dispose of both at leisure. Is very bold and aggressive when nesting, attacking crows and raptors encroaching on the vicinity of the nest-tree, while tolerating harmless species like bulbuls.

FOOD. Insects: largely (and regularly) butterflies even of the genera *Danaus* and *Euploea* repugnant to most other birds and to lizards; dragonflies, winged termites, etc. Occasionally nectar of flowers, e.g. *Erythrina indica*.

VOICE and CALLS. Distinctive, harsh cries *chek-chek-chek* (or *chake-chake-chake*) etc. uttered at rest and in flight, audible from a considerable height. Song (♂?) from bare tree-top in breeding season described by SA as

SWALLOW-SHRIKES

145

rather subdued, commencing and ending with the harsh *chaks*. A medley of pleasant twittering snatches of 10-15 seconds duration, repeated again and again for over 10 minutes with short pauses during which the bird switched its tail slowly up and down. Was reminiscent of Swallow's twittering song, soliloquy of Rufous-backed Shrike and chattering ditty of Rosy Pastor, as well as the soft warbling of Blyth's Reed Warbler (*Acrocephalus dumetorum*). Imitations of many bird-calls were interlarded in the song, those of Jungle Myna (softer) and Red-whiskered Bulbul being clearly recognizable.

BREEDING. Season, in India principally March to June; in Ceylon January to June, chiefly March. *Nest*, a loosely put-together shallow cup of fine grass, roots and fibres with sometimes a few feathers but no definite lining. Placed in a crotch or elbow of some horizontal bough — very commonly in the angle at the base of leaf-stalks in a palmyra, coconut or other palm — often at considerable heights from the ground. *Eggs*, 2 or 3, greenish white spotted with light brown chiefly at the broad end, sometimes forming a cap. Average size of 50 eggs 23.4 × 17.1 mm (Baker). Both sexes take part in building the nest, incubation, and tending the young. Incubation period unrecorded.

MUSEUM DIAGNOSIS. Rump somewhat paler than back, slaty grey-brown with a vinous tinge; longer upper tail-coverts white.

Young (immature) resembles adult but upperparts, except the whitish tail-coverts, brown with tiny fulvous margins, mostly on mantle; tiny pale tips to median, greater and primary coverts. Throat browner; rest of underparts dirty fulvous white with narrow indistinct brownish bars. Postjuvinal moult includes body, and apparently all coverts except primary.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	129-138 (145)	21-24	16-19	54-60 mm
♀♀	130-139	21-23	16-19	48-53 mm (SA, HW)

Weight 2 ♂ 37, 42; 3 ♀ 38-42 g (Paynter).

COLOURS OF BARE PARTS. Iris dark brown. Bill sky blue or greyish blue, black at tip; mouth dark slate. Legs and feet bluish slate or slaty brown; claws black.

983. Whitebreasted Swallow-Shrike. *Artamus leucorhynchus humei* Stresemann

Artamus leucorhynchus humei Stresemann, 1913, Novit. Zool. 20: 291 (Andamans)

Baker, FBI No. 764, Vol. 2:350
Plate 65, fig. 16

LOCAL NAMES. None recorded.

SIZE. Bulbul ±; dumpy with short tail. Length c. 18 cm (7 in.).

FIELD CHARACTERS. Above, head, and neck all round slaty grey; back purplish grey-brown; lower rump and upper tail-coverts white; tail and wings ashy black. Below, throat and upper breast slaty grey; lower breast and rest of underparts white. Sexes alike.

STARLINGS, MYNAS

147

Genus SAROGLOSSA Hodgson

Saroglossa Hodgson, 1844, in Blyth, Jour. Asiat. Soc. Bengal 13: 367.

Type, by monotypy, *Lamprolornis spilopterus* Vigors

Bill slender and gently curved; tongue less fleshy than in *Gracula*. Nostrils small and slender; rictal bristles short though strong. Feathers of crown somewhat lanceolate but short. Wing long and pointed: first primary (as.) very small. Tail short and square-cut.

984. Spottedwinged Stare. *Saroglossa spiloptera* (Vigors)

Lamprolornis spilopterus Vigors, 1831, Proc. Zool. Soc. London: 35

(Himalayan Mountains, restricted to Simla-Almora)

Psaroglossa spiloptera assamensis Baker, 1924, Bull. Brit. Orn. Cl. 45: 14

(Khasia Hills)

Baker, FBI Nos. 970, 971, Vol. 3: 25, 26

Plate 68, fig. 2

LOCAL NAME. Pali (Mussorie, U.P.).

SIZE. Bulbul ±; length c. 19 cm (7½ in.).

FIELD CHARACTERS. A spruce little gregarious myna reminiscent of the Greyheaded (*Sturnus malabaricus*, 987).

Male. Above, including crown, brownish grey scalloped with black. Below, chin and throat deep chestnut-rufous; rest of underparts rusty white. A prominent white patch in the blackish wings.

Female. Above, sooty brown; sides of head dark brown. Below, pale fulvous ashy brown scalloped with white, especially on chin and throat. White wing-patch as in male.

The typical starling-like flight, together with dark head, rufous-chestnut rump, and pointed blackish wings with a conspicuous white patch (as in Blueheaded Rock Thrush) diagnostic.

STATUS, DISTRIBUTION and HABITAT. Status equivocal and imperfectly known. From available data, is by and large an east-west migrant. Breeds in the western Himalayas from about Kangra in Himachal Pradesh (c. 32°N., 76°E.) to Garhwal and Kumaon (Dehra Dun, Simla, Almora). Flocks sight-recorded at c. 2000 m in Garhwal (Mandakini Valley, May-June — Lavkumar, JBNHS 53: 324). Passes westward along the lower hills, between c. 700 and 1200 m, in March-April through Nepal and Sikkim, and eastward again in June-July. Winters abundantly in Assam, from the foothills up to c. 1000 m, rather erratically in Nagaland (?), Manipur, and E. Pakistan (Dacca, Chittagong). May also breed occasionally (or regularly?) in between and in Assam, but this not proven. Affects open forest.

Extralimital. Burma south to N. Tenasserim (winter).

GENERAL HABITS. Arboreal and highly gregarious. Keeps in small or large flocks, sometimes of several scores or even hundreds as when feeding

× c. 1

146

STURNIDAE

STATUS, DISTRIBUTION and HABITAT. Endemic to Great and Little Coco, and Andaman islands. Affects openly wooded country, forest clearings, rubber plantations, etc.

Extralimital. Other subspecies in Malaysia, Philippines, Borneo, Sumatra, Java and associated islands, east to Australia.

GENERAL HABITS, FOOD, VOICE and CALLS. As in Ashy Swallow-Shrike (982) q.v. Has been recorded as settling freely on the ground, moving with very short hops to pick up insects and nesting material, several frequently together on roads (Hume).

BREEDING. Season, mainly April and May. *Nest*, as in Ashy Swallow-Shrike (982) — usually quite exposed; almost invariably placed on the broken-off stump of some stout branch, between c. 3.5 and 7 m from the ground. *Eggs*, 3, white, spotted with light brown or fawn chiefly in a zone at the broad end, with numerous underlying grey markings (BBO). Average size of 40 eggs 23.8 × 17.2 mm (Baker). Breeding biology as in 982.

MUSEUM DIAGNOSIS. Underparts white from breast downwards; upper tail-coverts as well as lower rump white.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂♀	127-134	16-17	15-16	55-60 mm (Baker)

COLOURS OF BARE PARTS. Iris pale blue, dark blue to deep brown. Bill pale blue tipped with black. Legs and feet dark slaty to practically black (Baker).

148

STURNIDAE

on large leafless *Salmalia* trees in flower, and in company with Greyheaded and Jungle Mynas (*Sturnus malabaricus* and *Acridotheres fuscus*). Very fond of nectar, the slender curving bill suggesting special adaptation for this diet. At the flowers often adopts blustering and bullying dog-in-the-manger tactics, like Rosy Pastor, assaulting and keeping other visitors off from the flowers although itself satiated. From time to time, for no apparent reason, a whole flock will suddenly dive into space from the leafless branches and wheel round and round the tree at top speed with lightning twists and turns and side-slips as if to dodge some invisible devil in pursuit! After a couple of rounds the birds re-settle and resume feeding complacently as before. Flight swift, very much like that of the starlings *Sturnus vulgaris* and *S. roseus*.

FOOD. Insects (red tree ants, winged termites, etc.); *Ficus* figs and various berries; in season, predominantly flower-nectar of *Salmalia*, *Bombax* and *Erythrina* species; also of *Gracillea* shade-trees in tea gardens.

VOICE and CALLS. Noisy chattering notes when in a flock, very similar to those of Greyheaded and Jungle mynas. A resentful or bellicose *chek-chek-chek*, with wings partially dropped and tail slightly cocked and expanded, while hopping from flower to flower with other bird visitors feeding in the vicinity. A soft *chik-chik* like chirruping of Yellowthroated Sparrow (*Petronia xanthocollis*, 1949) when sitting idly.

BREEDING. Season, chiefly April to June. *Nest*, a pad of green leaves and rubbish, in a natural tree-hollow or barbet hole, 6 to 10 m from the ground. *Eggs*, 3 or 4, pale stone colour or pale bluish green with small reddish brown specks and blotches. Average size of 30 eggs 25.4 × 18.0 mm (Baker). Breeding biology unrecorded.

MUSEUM DIAGNOSIS. For details of plumage see Baker, loc. cit.

Young (immature) female. Above, whole head and upperparts uniform grey-brown, a little paler than adult, with fulvous tips to lesser and median coverts and tertials; rump and upper tail-coverts fulvous brown; rest of wings and tail as in adult ♀ but rectrices narrower. Below, as in adult but more streaked than mottled, and washed with fulvous on flanks.

Young male said to differ from female, but not examined.

MEASUREMENTS

	Wing	Bill (from anterior edge of nostril)	Tail
♂♂	110-115	14-15	56-61 mm
♀♀	105-106	13-14	54-58 mm (Marien)

Tarsus 21-22 mm (Baker)

Weight 1 ♂ 47.5 g (BB).

COLOURS OF BARE PARTS. Iris dull white to lemon-yellow. Bill dusky black, reddish at base of lower mandible and pale yellow on margins of both mandibles. Legs, feet and claws black.

Genus APLONIS Gould

Aplonis Gould, 1836, Proc. Zool. Soc. London: 73. Type,

by original designation, *Aplonis marginata* Gould = *Lanius talaris* Gmelin

Lanius Bonaparte, 1853, Comp. Rend. Acad. Sci. Paris 38: 830. Type,

by original designation, *Lamprolornis fuliginis* Pucheran = *L. griseus* Salvadori

STARLINGS, MYNAS 149

Plumage intensely glossy. Bill fairly stout and gently curved; nostrils small and round. Wing long and pointed; tail of moderate length, well graduated. Tarsus and feet strong. Only the single species *panayensis* (Scopoli) occurs within our limits with two subspecies.

APLONIS PANAYENSIS (Scopoli)

Key to the Subspecies

- Plumage very dark and less glossy.....*A. p. tyleri*
- Plumage less dark and very glossy.....*A. p. affinis*

985. Tipperah Glossy Stare. *Aplonis panayensis affinis* (Blyth)

Calornis affinis 'A. Hay' = Blyth, 1846, Jour. Asiat. Soc. Bengal 15: 36 (Tipperah)

Baker, FBI No. 969, Vol. 3: 24

LOCAL NAMES. *Dao gogoui*, *Dao maina gajeba* (Cachari).

SIZE. Myna \pm ; length c. 22 cm (8 $\frac{1}{2}$ in.).

FIELD CHARACTERS. A smallish, comparatively slender black myna, brilliantly green-glossed all over and with conspicuous scarlet-crimson eyes (yellowish white in young, q.v.). Sexes alike.

STATUS, DISTRIBUTION AND HABITAT. Status equivocal. Thought to be summer (breeding) visitor to Assam in the Garo, Khasi and N. Cachar hills; arrives there c. February and departs

c. April with flying young. Occurs also in East Pakistan (Tipperah, Chittagong, Dacca). Locally common. A straggler (subspecies?) taken in Madras, 9 Oct. 1880 (W. F. Dique, SF 9: 298). Affects coconut groves, forest edges, and cultivation clearings with a scattering of large *Ficus* and suchlike trees.

Extralimital. Arakan. Other races in Burma, peninsular Thailand, Indo-chinese countries, Malay peninsula and archipelago, and Indonesian islands east to the Philippines.

GENERAL HABITS. Gregarious and sociable. Keeps in noisy flocks feeding in association with other mynas on *Ficus* and flowering trees. Congregates to roost in hundreds in coconut palms and other trees to the accompaniment of much squabbling and chattering. Chiefly arboreal but will sometimes descend to the ground to pick up fallen berries. Posture at rest, and flight, very starling-like.

FOOD. Insects, berries and small *Ficus* figs (e.g. *F. benjamina*), and flower-nectar (*Salmalia*, *Erythrina*, etc.).

VOICE AND CALLS. Very noisy when in flock; has a sharp metallic single note.

BREEDING. Very little known. In Cachar 'It breeds about April in the holes of dead trees; when the young are able to fly it departs. It again returns

150 STURNIDAE

about the middle of February' (J. Inglis in Hume, 1889, 1: 367). More information desirable.

MUSEUM DIAGNOSIS. Lores and feathers at base of upper mandible dull black; wings and tail black with faint blue gloss.

Young (immature). Upperparts dark brown with slight green gloss. *Below*, buffy white heavily streaked with brown and slightly glossed with green, the streak fine on chin and throat, heavier elsewhere except on belly which is nearly immaculate. Coverts, secondaries and tertiaries browner, slightly glossed and edged paler. Post-juvinal moult complete (Ticehurst).

MEASUREMENTS

♂♀ Wing 106-113 mm (Ticehurst).

COLOURS OF BARE PARTS. Adult. Iris crimson. Bill, legs, feet and claws black. Immature. Iris yellowish white turning to pale yellow with red-brown tinge, orange-vermillion, and finally crimson. Legs and feet brownish black (CBT).

986. Andaman Glossy Stare. *Aplonis panayensis tyleri* (Hume)

Calornis Tyleri Hume, 1873, Stray Feathers 1: 480 (Andamans)

Baker, FBI No. 968, Vol. 3: 23

Plate 68, fig. 1

LOCAL NAME. *Tukkulis* (Car Nicobar).

SIZE. Myna \pm ; length c. 22 cm (8 $\frac{1}{2}$ in.).

FIELD CHARACTERS. As of 985, q.v. See Key to the Subspecies and Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident and locally migratory: Andamans and Nicobars; found on nearly all the islands. Appears in Port Blair about February and remains till June: exceedingly numerous between these months. Absent for rest of the year; where the birds go unknown (Osmaston, JBNHS 17: 158). Affects coconut groves; also forest and open country with large trees.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 985.

BREEDING. Season, March to May, chiefly April. Nest, a natural hollow or woodpecker hole in a coconut trunk for preference, but also in padouk and other trees, generally at considerable heights. Eggs, 2(?) to 4, white to skim-milk blue with specks and small blotches of reddish brown. Average size of 30 eggs 26.6 x 19.7 mm (Baker). Breeding biology unrecorded.

MUSEUM DIAGNOSIS. Differs from *affinis* (985) in being darker, not so glossy bronze-green, the gloss more bluish green. Also has a longer wing, and larger and broader bill.

Young (immature) as in *affinis*.

MEASUREMENTS

♂♀ Wing 112-120 mm (Baker)

COLOURS OF BARE PARTS. Iris very variable: white, pink, brown, red-brown or deep orange. Bill, tarsus and toes black (CBT).

A new subspecies, *A. p. albis*, has since been described by Abdulali from Great Nicobar on the basis of eye colour, white s. brown in birds from Car Nicobar and the Andamans (type locality, Campbell Bay, Great Nicobar). Known distribution: Camorta, Trinkat, Nankowry, and Great Nicobar islands (Bull. BOC. 87 (2): 33-4. 1967).

(Nichuguard, Naga Hills)

Baker, FBI No. 982, Vol. 3: 39

Plate 68, fig. 3

LOCAL NAMES. *P  wei* (Hindi); *D  ri p  wei* (Bengal); *Kat halik* (Assam); *Meina gophu* (Cachar); *P  li palisa* (Telugu); *Ch  r  kkili* (Malayalam).

SIZE. Myna --; length c. 21 cm (8 in.).

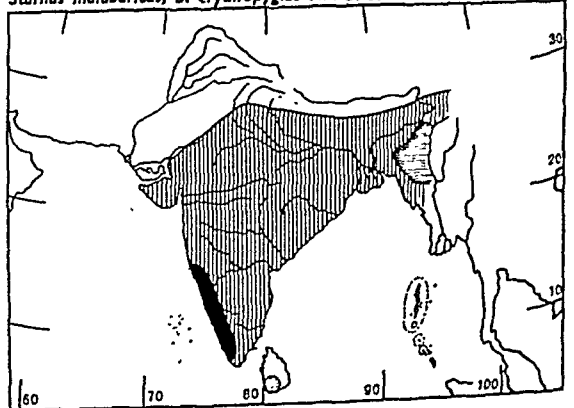

FIELD CHARACTERS. A small, trim, silvery grey-and-rufous sociable myna. Above, head and upperparts silvery- or brownish grey; tail largely ferruginous. Wing-quills black and grey. Below, chin, throat and breast lilac-grey or pale rufous; rest of underparts bright rufous. Sexes more or less similar. See Museum Diagnosis.

x c. 1

STATUS, DISTRIBUTION AND HABITAT. Resident, with marked seasonal local migrations and erratic wandering movements, especially during the SW. monsoon and in winter. Practically throughout the Indian Union

- S. s. senex* (993)

STARLINGS, MYNAS

153

(south to Kanyakumari) and E. Pakistan, roughly east and south of a line from Mt Abu in Rajasthan to Dehra Dun in U.P. (straggling to Simla and Ambala); thence eastward along the lower Himalayas and submontane tracts through Nepal, Sikkim, Bhutan and NEFA; normally up to c. 1500 m in the Himalayas and peninsular hills, locally to c. 2000 m. Evidently breeds at least south to about 17°N.; replaced in southwestern India by 988. In winter both grey-headed and white-headed birds often in the same locality and even in a mixed flock. Represented in N. Cachar, Nagaland and Manipur by 989. Absent in Ceylon.

Affects thinly wooded country both near human habitations and in outlying parts, and open secondary jungle. Partial to young forest plantations.

GENERAL HABITS. Gregarious and predominantly arboreal, but will frequently descend to feed in low bushes and occasionally on the ground. Keeps in small flocks of 5 to 20 or larger ones of several scores, by itself or in association with Rosy Pastors and other mynas as when feeding on flowering trees. The birds hop actively from one flower bunch to another keeping up a lively chatter and squabbling the while. Hunts insects among the foliage canopy walking purposefully along the branches, clinging to the bark in all manner of acrobatic positions, and peering into nooks and crannies. Flight swift and typically starling-like: a few rapid beats of the pointed wings followed by a short glide. Large congregations collect to feast on winged termites emerging from rain-sodden soil in company with drongos and other insectivorous species. The birds, in ones and twos or several together, spring up vertically from the ground or a bush-top closing the wings and halting in mid-air for a split second while they neatly snap up the quarry, before diving back to the perch. While feeding on a lofty leafless flowering Silk Cotton a flock will suddenly—as at a word of command—and for no apparent reason, dive helter-skelter into space as if to dodge the stoop of some imaginary raptor and will circle round the tree at high speed once or twice before re-settling and resuming activity as before, with no sign of nervousness (cf. 984).

FOOD. Fruits and berries; flower-nectar; insects. Among the first, most commonly recorded are: *Zizyphus* (esp. *oenophia*), *Lantana aculeata*, *Inga dulcis*, and wild figs of many species (*Ficus bengalensis*, *F. religiosa* and others). Nectar of *Salmalia malabarica*, *Bombax insignis* and species, *Erythrina indica*, *E. suberosa* and *E. lithosperma*, *Butea monosperma* and occasionally *Loranthus* spp. the birds helping to promote cross-pollination in many of these. In an intensively cultivated area in Bihar the following insects identified among stomach contents: weevils [*Tanymericus* sp. (*hispidus*?), *Astycus lateralis*]; beetles (*Myliocerus maculosus* and spp.), in addition to gryllids, hemipterous bugs and geometrid caterpillars. Nest-young observed to be fed on melolonthid, geometrid and noctuid larvae (Mason & Lefroy, 1912).

VOICE AND CALLS. A sharp disyllabic metallic note; uttered also when just taking off and during flight. A mild, rather tremulous single whistle (Nichols). Song: a pleasant warble (Hume, Jones).

BREEDING. Season, overall April to July, the principal periods varying with locality. Nest, a collection of twigs, rootlets and grass placed in a barbet- or woodpecker hole in a tree-stem, normally between 3 and 12 metres from the ground. Eggs, 3-5, pale blue-green, unmarked. Average size of

STARLINGS, MYNAS

155

(July) and Ahmedabad (August). Frequently found in mixed flocks together with Greyheaded Myna in non-breeding season. Due to this and consequent ambiguity in sight records, exact status and distribution as yet imperfectly known. Habitat as under 987.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in 987.

BREEDING. Season, February to May. Nest, eggs (c/3) and breeding biology as in Greyheaded Myna (987). Average size of 15 eggs 23.8 × 17.9 mm (Baker).

MUSEUM DIAGNOSIS. Male differs from male *malabaricus* in having the whole head, chin, throat and breast white; upper tail-coverts with less rufous or none; under tail-coverts constantly more rufous, never quite white as sometimes in *malabaricus*.

Adult female differs from adult male (*above*) as follows: 1. White of head confined to forehead and forecrown; rest of crown and nape concolorous with back but much streaked with pale grey, 2. Silvery grey on wings and tail less pronounced, 3. Sides of head and neck largely grey instead of white, 4. Pure white on underparts confined to chin and throat; breast sullied grey merging into the creamy rufous of abdomen and flanks (which are rich rufous in male); under tail-coverts paler and more fulvous.

Adult female *blythii* differs from adult female *malabaricus* as follows: 1. Upperparts purer more silvery grey v. more brownish grey, 2. Underparts much paler: chin and throat pure white; breast white, sullied with grey and rufous; rest of underparts and flanks creamy rufous; under tail-coverts pale rufous.

Young (immature) not distinguishable from juvenile *malabaricus*.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail

♀♀	97-104	22-25	23-26	59-65 mm

(SA, Marien)

Bill from anterior edge of nostril: ♂♂ 14-16 mm (Marien).

COLOURS OF BARE PARTS. As in 987.

989. Whitewinged Myna. *Sturnus malabaricus nemoricola* (Jerdon)

Sturnia nemoricola Jerdon, 1862, Ibis: 22 (Thayetmyo, Upper Burma)
Baker, FBI No. 987, Vol. 3: 42

LOCAL NAMES. None recorded.

SIZE. Myna —; length c. 21 cm (8 in.).

FIELD CHARACTERS. As of 987, q.v., but with forehead, crown, chin, throat and breast clear pearly grey (without white shafts), and underparts pale rufous buff to almost white. Sexes alike. See also Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident and common. North Cachar, Nagaland, Manipur: foothills and up to c. 1200 m. Affects secondary forest with scattered large *Salmalia* trees, and semi-cultivation.

Extinct. Burma, Thailand, Yunnan, Indochinese countries.

GENERAL HABITS. Very similar to Greyheaded Myna (987). Keeps in small parties or flocks, often of considerable size. Feeds up in flowering and

154

STURNIDAE

50 eggs 23.8 × 18.2 mm (Baker). Both sexes take part in building the nest, incubation, and tending the young. Incubation period undetermined.

MUSEUM DIAGNOSIS. Male. *Above*, forehead feathers over eyes whitish; cheeks and ear-coverts pale rufous-grey; shafts of feathers of head and neck whitish. Rest of upperparts dark grey tinged with ferruginous on rump and upper tail-coverts. Central tail-feathers frosted grey; rest blackish at base, dark ferruginous at tips, this increasing towards outer pair. *Below*, chin, throat and breast rufous-grey, the feathers with white shafts; rest of underparts deep ferruginous, but under tail-coverts sometimes white. Feathers of crown, nape, throat and upper breast hackled.

Female. Normally indistinguishable from male. Some have the hackles shorter and less defined; head similar to back without the white; underparts paler or even whitish.

Young (immature). 'Upperparts grey-brown, palest on head; indistinct pale supercilium; upper tail-coverts with a rusty tinge; sides of head and underparts dirty buffy white; wings and tail dark brown without grey frosting and with paler brown outer edges to wings and coverts; the deep ferruginous of tail replaced by paler rufous tips, less in extent; tail-feathers narrower. Postjuvinal moult complete' (Ticehurst).

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	93-106	21-24	23-25	59-65 mm
♀♀	94-104	20-22	22-24	55-65 mm

(HW, BB, Marien)

Bill from anterior edge of nostril: ♂♂ 12-15; ♀♀ 12-14 mm (Marien).

Weight 16 ♂♂ 32-44 (av. 39.9) g—SA. 3 ♂♂ 34.5-42.5; 2 ♀♀ 36.5, 39.5 g (GD, BB).

COLOURS OF BARE PARTS. Iris greyish- or creamy white. Bill cobalt or leaden blue at base, yellow at tip, with a greenish intermediate area; palate dusky yellow, gullet pinkish grey or slaty. Legs, feet and claws yellowish brown, brownish flesh, or pale lemon-yellow.

988. Whiteheaded Myna. *Sturnus malabaricus blythii* (Jerdon)

Pastor Blythii Jerdon, 1844, Madras Jour. Lit. Sci. 13: 133 (Malabar)
Baker, FBI No. 983, Vol. 3: 40
Plate 68, fig. 4

LOCAL NAMES. *Pāli palisa* (Telugu); *Chārākkili* (Malayalam).

SIZE. Myna —; length c. 21 cm (8 in.).

FIELD CHARACTERS. As of 987, q.v., but whole head, chin, throat and breast white in male. For details of plumage and distinction between male and female, and between female *blythii* and very similar female *malabaricus* see Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident, subject to seasonal local migration like *malabaricus*. Breeds in southwestern peninsular India, in Kerala (including Wynaad) and western Mysore (Coorg dist.) up to c. 1200 m; perhaps north to Belgaum (c. 16°N.). Migrates and/or straggles sporadically northward in the rains and winter. Specimens from Bombay

156

STURNIDAE

fruiting trees—sometimes on the ground—chiefly in the morning and late afternoon, sheltering in shady trees during the heat of the day. Roosts in bushes in company with Pied and other mynas.

FOOD, VOICE AND CALLS. As in 987. 'A sharp metallic note continued during flight' (Davison). Diet largely nectar and wild figs (*Ficus* spp.).

BREEDING. Season, apparently April and May. Nest, eggs (c/3-6) and breeding biology as in 987. Average size of 14 eggs 25.6 × 19.0 mm (Baker).

MUSEUM DIAGNOSIS. Under tail-coverts, winglet and primary-coverts often white, sometimes black as in *malabaricus*, sometimes particoloured black and white; this apparently neither sexual nor due to age. Hackles as in *malabaricus*.

There is much variation. Usually the only ferruginous on the underparts is a small patch on flanks covering the thighs. But occasionally underparts distinctly suffused with ferruginous. Head colour varies individually and with wear, but is never so dark grey as in *malabaricus*. Even in fresh plumage head and throat may be very pale grey or almost pure white thus closely resembling *blythii* except for the belly which is not ferruginous.

Young (immature) indistinguishable from *malabaricus*.

MEASUREMENTS

Wing ♂♂ ♀♀ 94-103 mm (Baker)

COLOURS OF BARE PARTS. As in 987.

STURNUS ERYTHROPS (Blyth)

Key to the Subspecies

	Page

990. Andaman Whiteheaded Myna. *Sturnus erythropus andamanensis* (Tyder)

Temeruchus andamanensis Tyder, in Beavan, 1867, Ibis: 329 (Andamans)
Baker, FBI No. 984, Vol. 3: 41

LOCAL NAMES. None recorded.

SIZE. Myna —; length c. 21 cm (8 in.).

FIELD CHARACTERS. Similar to Whitewinged Myna (989), q.v., but with whole head, neck, and underparts creamy white; back and scapulars pale grey; rump and upper tail-coverts paler grey, faintly tinged with fulvous. Sexes alike. See keys to the Species and Subspecies, and Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Resident; very common. Andaman Islands. Affects forest and secondary jungle. Introduced on Camorta, Nicobars.

GENERAL HABITS. As of Greyheaded Myna (987). Keeps in small parties and large flocks in and around paddyfields, open grassland and forest edges, and on hillsides. Associates with drongos, cuckoo-shrikes, minivets, etc. in the itinerant foraging bands.

STARLINGS, MYNAS

157

FOOD. Nectar, fruits and berries, and insects. Very partial to a small caterpillar which rolls itself up in narrow bamboo leaves¹, the birds adopting all sorts of tit-like attitudes to investigate the infested leaves (Butler, JBNHS 12: 397-8).

VOICE and CALLS. Not specifically recorded. Presumably as in 987 and 989.

BREEDING. Season, March to May. Nest, of small pliant twigs lined with small green leaves; placed in a tree-hole 2 to 10 metres from the ground. Eggs, 4, uniform blue similar to those of *Sturnus malabaricus* and also *Acridotheres tristis*. Average size of 40 eggs 25.8 × 18.9 mm (Baker). Both sexes take part in all domestic chores.

MUSEUM DIAGNOSIS. Only feathers of crown hackled. Wings and tail black glossed with green. Central rectrices with hardly any white tips; small tips to next pair and increasingly larger ones to outer pair which are half white. Under wing-coverts and axillaries white. Bill more massive and longer than in *S. m. nemoralis* (1989).

Young (immature). 'Very similar to adult' (Butler).

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	103-113	20-21	27-28	75-76 mm (Baker)
2 ♂♂	107+, 117	20, 21	—	76, 78 mm
2 ♀♀	107, 108	20, 21	—	72, 74 mm (Abdulali)

COLOURS OF BARE PARTS. Iris opalescent white to very pale blue. Bill greenish yellow, small blue at base. Legs and feet lemon- or fleshy yellow.

991. Nicobar Whiteheaded Myna. *Sturnus erythrogygius erythrogygius* (Blyth)
Sturnia erythrogygia Blyth, 1846, Jour. Asiat. Soc. Bengal 15: 34
(Nicobar islands, restricted by Ripley, 1961, to Car Nicobar)
Baker, FBI No. 985, Vol. 3: 41
Plate 68, fig. 8

LOCAL NAMES. *Halat*, *Harotich* (Car Nicobarese).
SIZE. Myna —; length c. 21 cm (8 in.).
FIELD CHARACTERS. As of 990, q.v. Sexes alike. See Key to the Subspecies and Museum Diagnosis.
STATUS, DISTRIBUTION and HABITAT. Nicobar islands; so far known only on Car Nicobar where quite common. Habitat as in 990; partial to casuarinas and coconut palms in the coastal belt.
GENERAL HABITS, FOOD, VOICE and CALLS. As in 987 and 989. Large numbers congregate in the evening to roost in old casuarina and other trees.
BREEDING. Season, April; perhaps more correctly March to May as in the Andaman form. Nest, the only three known were as described under

¹ Probably larva of the common Pyralid, *Pyrausta nectalis*.

STARLINGS, MYNAS

159

993. Ceylon Whiteheaded Myna. *Sturnus senex* (Bonaparte)
Heterornis (Pastor) senex Bonaparte, 1850, Cons. Gen. Av. 1: 419
(¹ ex Beng. ² errors = Ceylon)
Cf. Ticehurst, C. B., 1940, *Ibis*: 148-9
Baker, FBI No. 990, Vol. 3: 46
Plate 68, fig. 7

LOCAL NAMES. Not specifically recorded.
SIZE. Myna —; length c. 22 cm (8½ in.).
FIELD CHARACTERS. A trim smallish myna, reminiscent of the Greyheaded (987).
Above, forehead and sides of head white; crown and rest of upperparts blackish slate; feathers of nape and neck white-shafted. Below, chin and throat white, rest of underparts dusky lavender-grey (streaked with white on neck and breast) paling to whitish on belly and under tail-coverts. Wings and tail green-glossed black. Sexes alike.
STATUS, DISTRIBUTION and HABITAT. Species endemic to Ceylon: Not abundant. Confined to well-wooded hills in the southwestern Wet zone, including Adam's Peak, up to c. 1300 m. Affects tall forest and the adjacent clearings.

Could be regarded as the Ceylon form of *Sturnus malabaricus*.
GENERAL HABITS. Not different from Indian Greyheaded and White-headed mynas. Like them, sociable and almost entirely arboreal.
FOOD. Fruits and berries, and insects; also flower-nectar (*Salmalia*, *Grevillea*, etc.).
VOICE and CALLS. 'A starling-like chirp' (Legge). 'A single note *cheer* with the tone of a grackle's, and the bird bows and scrapes like a myna' (W. W. A. Phillips's correspondent from Rakwana in *epist.*).
BREEDING. Apparently known only from a single nest in a tree-hole (April). It contained 2 pale blue eggs measuring c. 25 × 20 mm.
MUSEUM DIAGNOSIS. Feathers of crown and nape hackled. White shafts of nape and neck feathers, coloration of underparts, and amount of white on head very variable. Under wing-coverts dusky. A small bare bluish patch behind eyes.
Young (immature). Upperparts dull brown; supercilium whitish; ear-coverts sullied white. Underparts much as adult, but conspicuous white shaft-lines absent. Wings and tail brown. Postjuvénal moult complete (Ticehurst).

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	105-110	c. 20-21	c. 26	69-73 mm (Baker)
1 ♂	112	(from skull) 23	—	73 mm (SDR)

COLOURS OF BARE PARTS. Iris dull white with narrow brown inner circle; orbital skin and eyelids bluish. Bill bluish brown, base of lower mandible plumbeous blue. Legs and feet bluish plumbeous.

STURNIDAE

158

990, and built in holes c. 3 or 4 metres up in Screw Pines (*Pandanus*) on the fringe of forest along the beach (D. B. Osmaston). Eggs, 4, unmarked uniform blue. Average size of 8 eggs 26.2 × 18.7 mm (Baker). Breeding biology not described; presumably as in *andamanensis* (990).

MUSEUM DIAGNOSIS. Only feathers of crown hackled. Rump, upper tail-coverts, vent, under tail-coverts, and tips of rectrices deep chestnut; sometimes a chestnut tinge on scapulars and under wing.

Young (immature). Like adult, but crown with narrow brownish grey shaft-streaks; belly tinged with creamy fawn; upper wing-coverts, secondaries and tertials narrowly edged with fulvous (A. L. Butler).

MEASUREMENTS

	Wing	Bill	Tail
3 ♂♂	110-112	23-24	76-78 mm
2 ♀♀	106, 108	22, 23	65, 71 mm (Abdulali)

Wing ♂ ♀ 112-120 mm (Baker)

COLOURS OF BARE PARTS. Adult as in 990. Juvenile. Iris pale grey. Bill yellow or greenish yellow above; base of lower mandible flesh-pink. Legs and feet dirty yellow (Butler).

992. Katchal Whiteheaded Myna. *Sturnus erythrogygius katchalensis* (Richmond)
Sturnia erythrogygia katchalensis Richmond, 1902, Proc. U.S. Nat. Mus. 25: 293
(Katchal, Nicobars)
Baker, FBI No. 986, Vol. 3: 42

LOCAL NAMES. None recorded.
SIZE. Myna —; length c. 21 cm (8 in.).
FIELD CHARACTERS. As of 990 and 991, q.v. See Key to the Subspecies and Museum Diagnosis.
STATUS, DISTRIBUTION and HABITAT. Katchal Island, Nicobars.
GENERAL HABITS, FOOD, VOICE and CALLS. Nothing recorded; presumably as in 990 and 991.
BREEDING. Not recorded.
MUSEUM DIAGNOSIS. Stands midway between *andamanensis* and *erythrogygius*, possibly a hybrid form. Has the pale grey rump and upper tail-coverts of *andamanensis* and the rufous belly, thighs and under tail-coverts of *erythrogygius*.

MEASUREMENTS

	Wing	Bill	Tail
1 ♂	107	—	64 mm
1 ♀	106	22	64 mm (Abdulali)

Wing 106, bill 21.5, tarsus 25.5, tail 71 (Richmond)

COLOURS OF BARE PARTS. Not recorded; doubtless as in 990.

(Tagan, Afghanistan)
Baker, FBI No. 991, Vol. 3: 47
Plate 68, fig. 5

LOCAL NAMES. *Pepoya myna*, *Brāhmīni myna*, *Pūhāia*, *Kālasit myna* (Hindi); *Menghyr pāri* (Calcutta dealers), *Bāmīni myna*, *Harbolā* (Bengal); *Pahiya pāri* (U.P., Mathura); *Pāpāta gurinki* (Telugu); *Pāpāta pāriki*, *Pāpāthi nākanarāi*, *Raveneti* (Tamil); *Kārimālaichikkili* (Malayalam); *Martintu* (Portuguese in Ceylon); *Nākanam pāshi* (Tamil in Ceylon).
SIZE. Myna —; length c. 22 cm (8½ in.).
FIELD CHARACTERS. A crested myna, grey above reddish fawn below, with glossy black forehead, crown and nape and long pointed crest. Wings

black; tail brown with white edging and tip, particularly conspicuous when the bird spreads it before alighting. Sexes alike, but crest of female shorter.
Young (immature). General coloration dull: back browner grey, head sooty brown and crestless.
STATUS, DISTRIBUTION and HABITAT. Mainly resident, locally common but capricious, and subject to marked seasonal movements especially in the monsoons. Summer visitor (c. April) to the northern cold-winter parts. Absent in arid semi-desert and desert tracts as well as in humid evergreen biotope. West Pakistan roughly east of the Indus Valley; common summer visitor to Gilgit and Chitral, arriving there in April/May and breeding at between 1500 and 1600 m (Fulton, JBNHS 16: 49). All India from southern Kashmir, Himachal Pradesh and the Himalayan foothills (normally up to c. 1400 m, locally to 2400 m) southward to Kanyakumari; from eastern Rajasthan, northern Gujarat and Kutch eastward to about the longitude of Calcutta, c. 88°E. in W. Bengal. Rare or straggler in Assam and E. Pakistan. Not recorded in Nepal, Sikkim or Bhutan. Resident and widely distributed in Ceylon in the low-country Dry zone and coastal belt. Affects open deciduous forest and scrub jungle, and the neighbourhood

STARLINGS, MYNAS

161

of cultivation and human habitations, freely entering wooded urban gardens and compounds.

GENERAL HABITS. Sociable; less arboreal than Greyheaded Myna. Keeps in family parties of 4 to 7 banding into larger flocks where food is plentiful, and at the communal roosts. Associates freely with Greyheaded myna and other frugivorous and nectar-eating birds to feed on flowering and fruiting trees, and with Pied, Jungle and Indian mynas to hunt grasshoppers etc. disturbed by grazing cattle on marshy grassland and moist tank margins. Stalks about amongst the animals' legs with the typical jaunty upright carriage of mynas, darting at and seizing the fleeing insects. Flight less swift and starling-like than Greyheaded myna. Roosts in large congregations in leafy trees and shrubs such as mango and palas (*Butea*), or in reedbeds, in the noisy company of parakeets, rosy pastors and common mynas.

FOOD. Fruits and berries: lantana, *Zizyphus*, wild figs (*Ficus* spp.), *Salvadora persica* and *S. oleoides*, *Bridelia*, *Mimusops hexandra*, and others. Has been recorded eating the poisonous fruits of Yellow Oleander (*Thevetia nerifolia*), and the fleshy flowers of mhowa (*Madhuca indica*) commonly. Nectar of flowers: *Erythrina*, *Salmalia*, *Butea* and *Capparis* among the most usual, the birds doubtless promoting their cross-pollination. Insects: grasshoppers, moths, caterpillars, etc.

VOICE AND CALLS. Amusing merry creaking and chattering notes. In breeding season, a pleasing little rambling warbling song delivered by male from a shady perch in the nature of a soliloquy with his crest partially raised and whole plumage frowzled. It is interlarded with passable mimicry of bulbul, drongo and other birds' calls.

BREEDING. Season, overall February/March to August/September, the principal periods varying with locality; earlier in south India later in the north. Equivocal in Ceylon: believed to be July–August. Nest, a collection of grass, dead leaves, feathers and rubbish stuffed in a hole in a tree-trunk or bough — usually with a very small entrance — often usurped from a tit, barbet or woodpecker; or in a wall or roof even of inhabited houses. Is not averse to nesting colonially if suitable holes available close together. Eggs, 3 or 4, pale blue, unmarked. Average size of 100 eggs 24.6 × 19.0 mm (Baker). Both sexes take part in building the nest, incubation and tending the young. Incubation period undetermined. Two, sometimes three, broods raised in succession.

MUSEUM DIAGNOSIS. Wings blunter than in Grey- and Whiteheaded mynas (987–993), and tarsi stouter. Tail slightly graduated. For details of plumage see Baker, loc. cit.

Young (immature). Forehead to nape dark brown and crestless; grey upperparts, edges of coverts and of secondaries suffused with rufous-brown. Underparts paler and pale streaks to long hackles absent, otherwise as adult. Rectrices narrower. Postjuvénal moult complete and first-winter bird cannot be distinguished from adult. No spring moult. Complete autumn moult in October/November.

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	99–112	20–24	26–30	60–75 mm

996. Rosy Starling or Rosy Pastor. *Sturnus roseus* (Linnaeus)

Turdus roseus Linnaeus, 1758, Syst. Nat., ed. 10, 1: 171

(Lapland, Switzerland)

Baker, FBI No. 972, Vol. 3: 29

Plate 68, fig. 10

LOCAL NAMES. *Gulabi myna*, *Tifery* (Hindi); *Lal myna* (Bengal); *Ganggaya* (Bihar *mirshikars*); *Wyha*, *Wahero*, *Wyho* (Kutch, Sind); *Pariki pitta*, *Palisa* (Telugu); *Surai kūrūri*, *Chōlām kūrūri* (Tamil).

SIZE. Myna ±; length c. 23 cm (9 in.).

FIELD CHARACTERS. A distinctive rose-pink starling, or myna, with glistening black head, neck and upper breast, wings and tail. A long pointed

crest on crown and nape, recumbent at rest, partially raised under excitement and when singing. Pointed wings; swift and direct typically starling flight. Sexes alike.

Young (immature). Crestless, pale sandy brown with darker wings and tail; confusingly different from adult.

STATUS, DISTRIBUTION AND HABITAT. Winter visitor to West Pakistan and India eastward to Bihar, straggling (rarely) into W. Bengal, Assam and E. Pakistan. Southward throughout the Peninsula: abundant in Gujarat and the Deccan, decreasingly through Mysore, Kerala and southern Tamil Nadu. Irregular and sparingly in Ceylon chiefly in the northern districts and coastal areas of the Dry zone. Vagrant or irregular visitor to the Andaman Islands.

In many areas of W. Pakistan (N. Baluchistan, NW. frontier districts, Gilgit, Chitral) and NW. India (Punjab) mainly an abundant two-way passage migrant, recorded as such at up to 3000 m alt.; practically absent during the winter months.

Affects open cultivation, grassland, and low thorn jungle in semi-desert. Avoids forest.

Extralimital. Breeds in SE. Europe (west to Hungary) and SW. Asia (Asia Minor, Middle East countries, Russian Turkestan, etc.). For details see Vaurie, 1959, 2: 125–6.

162

STURNIDAE

Weight 9 ♂ ♀ 40–54 (av. 49) g — SA.

COLOURS OF BARE PARTS. Iris bluish white or yellowish cream colour. Bill, basal half including gape and nostrils greenish lead, terminal half lemon-yellow; mouth greenish plumbeous or bluish slate. Legs, feet and claws lemon-yellow.

995. Daurian Myna. *Sturnus sturninus* (Pallas)

Gracula sturnina Pallas, 1776, Reise Russ. Reich 3: 695 (Dauria)

Baker, FBI No. 988, Vol. 3: 43

Plate 68, fig. 6

LOCAL NAMES. None recorded.

SIZE. Myna —; length c. 19 cm (7½ in.).

FIELD CHARACTERS. A small greyish myna reminiscent of the Grey-headed, with very short blackish slightly forked tail, and two whitish wing-bars. Above, Crown and sides of head and neck hoary grey; lores and a ring round eye white; back, rump, wing-coverts and a patch on nape metallic blackish purple. A buff band across rump. Below, pale grey, the chin tinged with rufous. Tail metallic green, edged on the outside with buff. Sexes more or less alike; see Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Aberrant straggler. There are only two definite records from within our limits: a specimen collected in Chitral (head of Turikho Valley, c. 3300 m) from a flock of 17 birds on 16 July 1902 (Fulton, JBNHS 16: 49), and another which flew on board ship in a squall in the open sea between Car Nicobar and Little Andaman I. on 20 March (Hume, SF 2: 250, footnote). Said to be an occasional winter visitor to the Nicobars; possibly also to the Andaman islands.

Extralimital. Transbaikalia and N. Mongolia, Ussuriland, Manchuria, N. Korea, etc. Migrating through China to winter in S. China, Hainan, the Indochinese countries, Burma, Malay Peninsula and Indonesia. (For details see Vaurie, 1959, 2: 124.)

GENERAL HABITS, FOOD, VOICE AND CALLS. As in Greyheaded Myna (987), q.v. Keeps in flocks to open cultivated country.

BREEDING. Extralimital. In tree-holes.

MUSEUM DIAGNOSIS. Female resembles ♂ but dull brown replaces glossy black on upperparts, wings and tail. Hoary grey of head and upper back less marked; nape-patch dark brown instead of purple-glossed black. Underparts creamy white.

MEASUREMENTS

	Wing	Bill (from feathers)	Tarsus	Tail
♂ ♀	105–110	14–15	c. 25	52–54 mm (Hartert)

COLOURS OF BARE PARTS. Iris brown. Bill dusky; lower mandible whitish, to greenish blue from base to arch of gonys. Legs and feet greenish horn.

164

STURNIDAE

MIGRATION. One of our earliest migrants; fair numbers of adults (♂?) accompanied by a few young of the year entering the northwestern parts of the subcontinent already by middle, or even first week July; bulk passage of adults and young between August and October. Return transit in March and April continuing into mid May. Thus the birds totally absent from the subcontinent only for less than three months in the year. Enlargement of male gonads to breeding size in April–May, combined with presence of brood-patch in both sexes in unmoulted nuptial plumage of the earliest arrivals in July have led to postulation of the birds breeding within our limits or immediately adjoining areas (i.e. in Sind, Baluchistan, Afghanistan). However, this not yet proven except for a single circumstantial record in Afghanistan (see Marien, JBNHS 49: 480).

Is one of the exceptional species with a remarkable East-West migrational movement (*contra* North-South), comparable with that of the Blackheaded Bunting (*Emberiza melanocephala*, 2043). Adequate observational evidence in this regard is supported by ringing data (though only a single record as yet): a nestling ringed in NE. Hungary (47°55'N., 20°30'E.) on 30.vi. 1925, recovered near Lahore, W. Pakistan (c. 31°30'N., 74°30'E.) on 24.iv. 1926 — a map distance of some 4800 km. For a good summary of the movements of the Rosy Pastor within the country see Abdulali, JBNHS 46: 704–8. Large-scale emigration in progress observed earlier in N. Afghanistan in April–May and again in late March across the Great Rann of Kutch, probably represents the normal pattern of Rosy Pastor's migratory flight. Small parties and large flocks of 50–300 birds followed one another in an intermittent stream, flying swiftly and purposefully in a NW. direction, chiefly between 0830 and 1100 hrs, some sweeping low over the bush-tops, others perhaps 100 to 150 metres up. Parties occasionally alighted on the bushes but with no apparent inclination to feed; the birds seemed restless and presently took off again to join the hurrying bands.

GENERAL HABITS. Keeps in small parties or large flocks, sometimes of swarm proportions, in the neighbourhood of cultivation, especially jowar and bajra. The birds descend on the fields in 'clouds' often causing enormous damage to the ripening grain. Feeds actively in the morning and forenoon and then again in the late afternoon. Retires to rest in shady trees fringing the fields during the heat of the day, spending the time between intermittent raids in noisy chatter and creaky warbling. Often attends grazing cattle, especially on waterlogged ground, in association with other myna species and cattle egrets to hunt insects disturbed in the grass. Is unfailingly present on flowering trees such as Silk Cotton (*Salmalia*), Coral (*Erythrina*) and Flame-of-the-Forest (*Butea*) to feed on the nectar, and largely instrumental in their cross-pollination and fertilization. Acts the blustering bully to keep other birds away from the flowers, attacking the visitors from a distant part of the tree even when itself satiated and not feeding. The aggressive Pastor droops, twitches and shivers its wings, spreads its tail flicking it sideways provocatively, utters a bellicose *chit chit chit* by way of war-cry as it charges down to supplant the newcomer. The bird promptly inserts its own bill into the chalice as if to celebrate the victory. Roosts communally in enormous thickly-clustered swarms, numbering maybe several thousand birds — often in company with

parakeets, mynas, crows, weaver birds and migratory sparrows — in thorn bushes, groves of babool trees, *Butea* jungle, coconut plantations and reed-beds. Also in leafy roadside avenues in urban areas, frequently right in the midst of a congested city bazaar, undeterred by the din and bustle of traffic or the glare of electric lights. The deafening clamour produced by a large concourse settling in for the night may, at a distance, be likened to a heavy monsoon downpour pattering off a roof on to a cement floor! Flight swift and direct, typical of the starlings. While hunting swarming grasshoppers the birds run along the ground jostling one another in their eagerness, springing into the air every now and again to snatch the escaping quarry. The grassfield ripples with the activity of chaser and chased as the seething mass of birds constantly leap-frog over one another or fly ahead to cut off the fleeing horde. Is highly beneficial as a wholesale destroyer of locusts in times of invasion, as well as an important agent of seed dispersal. The abundance of mulberry trees in the Chhanga Manga Forest Reserve in W. Pakistan, and other plantations in the canal areas of the Punjab — the base of the flourishing sports goods industry — is largely due to the Rosy Pastor aided by bulbuls and other frugivorous birds.

Dense masses collect regularly to drink and bathe at puddles left behind in drying-up jheels and tanks.

Food. Chiefly fruits, berries, flower-nectar, cereal grains and insects. The following items specifically recorded:

Fruits and berries: *Ficus* (many species), *Lantana aculeata*, *Zizyphus oenoplia*, *Bridelia hamiltoniana*, *Streblus asper*, grapes, mulberries (*Morus*), dates (in W. Pakistan), *Salvadora persica*, *Capparis aphylla*, 'chillies' (Ingilis).

Flower-nectar: *Salmalia malabarica*, *Bombax insigne*, *Erythrina indica* and *E. suberosa*, *Butea monosperma*, *Careya arborea*.

Insects: Largely locusts and grasshoppers (Orthoptera—Acrididae). From stomachs of specimens have also been taken beetles (Coleoptera) of the families Lucanidae, Elateridae, Tenebrionidae, Buprestidae, Scarabacidae, Curculionidae.

Likewise centipedes (Chilopoda—Scolopendridae), molluscs (Gastropoda—Helicidae), and spiders (Araneae).

Cereal grains: chiefly jowar (*Sorghum vulgare*) and bajra (*Pennisetum typhoides*).

VOICE and CALLS. Song lively and much prolonged: a jumble of harsh chattering noises intermingled with melodious warbling notes. The hackle-like feathers of throat and long black crest stand out prominently while the bird is singing.

BREEDING. Extralimital. Season, May–June. Nesting colonial; in holes and crannies on stony hillsides and amongst ruins, the breeding grounds shifting year to year largely with those of migratory locust swarms. Eggs, 3 to 5, pale blue.

For an excellent account of the food, feeding habits and breeding biology, see Serebrennikov, M. K., 1931, 'Der Rosenstar (*Pastor roseus* (L.)), seine Lebensweise und ökonomische Bedeutung in Uzbekistan (Turkestan)', *Jour. f. Orn.* 79: 29–56.

MUSEUM DIAGNOSIS. See Key to the Species and Field Characters.

STARLINGS, MYNAS

167

x c. 1

For distinguishing adult ♂♂ from *nobilior* (998), also green-backed, see under that subspecies.

STATUS, DISTRIBUTION and HABITAT. The commonest Starling on the Indian list. Passage migrant through Chitral and Gilgit in October–November and then again mid March to mid April, a few overwintering in the Valley (Scully, SF 10: 128).

Probably passes also through Kashmir and Himachal Pradesh, but winter ranges of the various races overlap, two or more forms sometimes even occurring in the same flock; therefore subspecific determination impossible unless specimens in the hand; sight records equivocal. Abundant winter visitor to rest of W. Pakistan (Baluchistan, Sind, Punjab), and northern India — Punjab, Delhi, Nepal terai, and the Gangetic Plain, east (rare) to Bihar, W. Bengal, Assam (?), and E. Pakistan. Southward to Rajasthan, N. Gujarat (including Kutch and Saurashtra), northern and western Madhya

■ Breeding
For winter ranges see text

1. *poltaratskyi* (997).
2. *nobilior* (998).
3. *porphyronotus* (999).
4. *minor* (1000).
5. *indicus* (1001).
6. *vulgaris* (RE) and other extralimital races.

Pradesh. Vagrants and stragglers liable to be met in far-flung localities, thus two recorded from Madras (Whistler, JBNHS 36: 587) and three collected from a flock of c. 12 near Bombay, November (Abdulali, *ibid.* 62: 161).

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail
♂♂	125–136	24–26	30–32	67–73 mm
♀♀	122–136	22–24	28–33	65–72 mm

Weight 5 ♂♂ 55–76; 3 ♀♀ 53–73 g (Paludan). 7 ♂♂ 70–80 g (SA).

COLOURS OF BARE PARTS. Iris brown. Bill horny brown, yellow at gape and on basal half of lower mandible; mouth bright lemon-yellow, gullet livid pink or greyish pink. Legs, feet and claws horny brown.

MISCELLANEOUS. Extensively netted and/or shot in West Pakistan and N. India as an epicurean delicacy, particularly on outward migration when the birds are very fat. In Afghanistan (where locally known as *Sach*) not molested by the populace because of the wide appreciation of its beneficial service to agriculture as a destroyer of locusts. In Iran there is a popular legend that anyone afflicted with a locust plague has only to travel to a certain well in Qazvin and get from it a bottle of water. He must take this bottle to the place where the locusts are, and break it on the ground; the Pastors will soon come and eat up the locusts! (A. C. Trott, JBNHS 56: 692.)

STURNIDAE

168

Sight-recorded at sea (subsp. ?) c. 40 miles west of Minicoy island, in December and January (Phillips, JBNHS 60: 582).

Affects damp grassland around marshes and jheels, and outskirts of cultivation and habitations — irrigated lawns etc.

Extralimital. Breeds in Siberia north to c. 60°N. from the Ural Mts to Lake Baikal; south to Kazakhstan and W. Mongolia. Winters also in eastern Iran and Afghanistan (apparently breeding locally in the northern part). For details see Vaurie, 1959, 2: 129.

MIGRATION. The only ringing data so far available is of a juvenile ringed in the Kumerovo Region of western Siberia (Leninsk-Kuznetsky, c. 54°N., 86°E.) on 25.v.59, recovered in West Pakistan (Lahore, c. 31°N., 74°E.) on 3.i.1960 — a straight-line map distance of c. 2900 km.

GENERAL HABITS, FOOD, VOICE and CALLS. As in 1001.

BREEDING. Extralimital. Breeding biology as in 1001, and other races.

MUSEUM DIAGNOSIS. 'Head, throat and ear-coverts purple; mantle and rump green; upper tail-coverts and scapulars green, the longest feathers often violet-blue at the tips; wing-coverts green, mixed with violet-blue on the larger feathers; a green pectoral band separates the purple throat from the rest of the underparts which are "bluebottle" blue and more violet-blue on the flanks. Under wing-coverts brown with broad buff edges' (Ticehurst).

For description of plumages and bionomics of the nominate subspecies (*vulgaris*) see Witherby *et al.*, 1938, 1: 40–44.

MEASUREMENTS	Wing	Bill (from skull)	Tarsus	Tail
♂♂	125–135	28–32	29–32	62–69 mm
♀♀	124–131	28–32	29–32	59–65 mm

COLOURS OF BARE PARTS. As in 1001.

998. Hume's or Afghan Starling. *Sturnus vulgaris nobilior* Hume

St.(urnus) nobilior Hume, 1879, Stray Feathers 8: 175 (Kandahar)
Baker, FBI No. 977, Vol. 3: 34

LOCAL NAMES. As for 997.

SIZE. Between bulbul and myna; length c. 20 cm (8 in.).
FIELD CHARACTERS. As of Kashmir Starling (1001), q.v. See Key to the Subspecies and Museum Diagnosis.

Very similar to Indian Starling (997), also with green-glossed upperparts, but in good sunlight, with binoculars it is often possible to pick out adult males in mixed flocks with tolerable certainty by their blacker appearance due to the finer and less amount of spotting on the underparts in winter.

STATUS, DISTRIBUTION and HABITAT. Winter visitor to W. Pakistan (Baluchistan, Sind, NW. frontier districts, Punjab); doubtless also adjoining northwestern India. Affects open country — cultivation and grassland, and lush margins of jheels.

STARLINGS, MYNAS

169

Extralimital. Breeds in Khorasan, Transcaspia and Afghanistan (Vaurie). GENERAL HABITS, FOOD, VOICE AND CALLS. As in 1001.

BREEDING. Extralimital.

MUSEUM DIAGNOSIS. 'Resembles *pollaratskyi* (997) but belly and flanks bright reddish purple, as also are the wing-coverts. Under tail-coverts glossed with purple. Scapulars, rump, and upper tail-coverts mostly green, sometimes mixed with purple-blue, especially on the longer feathers. Underwing darker with narrow whitish edges. In winter, spots smaller and whiter. Bill usually a little longer and slenderer, up to 30 mm' [from feathers] — Ticehurst.

MEASUREMENTS

	Wing	Bill (from skull)
♂♂	130-134	31-34 mm

Sturnus purpurascens dresseri Buturlin, 1904, Orn. Jahrb.: 208 (Askabad)

Baker, FBI No. 974, Vol. 3: 32

LOCAL NAMES. As for 997.

SIZE. Between bulbul and myna; length c. 20 cm (8 in.).

FIELD CHARACTERS. As of Kashmir Starling (1001), q.v. See Key to the Subspecies and Museum Diagnosis.

In good sunlight, with binoculars, bronze-green head (v. purple in 997 and 998) suggests identity.

STATUS, DISTRIBUTION AND HABITAT. Winter visitor to W. Pakistan (Baluchistan, Sind, NW. frontier districts, Punjab) and adjoining north-western India [Kashmir, Himachal Pradesh (Kangra), etc.]. Has been obtained in Nepal terai (Fleming).

Extralimital. Breeds in Chinese and Russian Turkestan south to Tadzhikistan and Pamirs. For details see Vaurie, 1959, 2: 129. Winters also in Afghanistan.

GENERAL HABITS, FOOD, VOICE AND CALLS. As in Kashmir Starling (1001).

BREEDING. Extralimital.

MUSEUM DIAGNOSIS. Head greenish but ear-coverts always more or less purple; mantle red-purple, in some specimens tinged with purple-blue; wing-coverts purple on the median and lesser series, bronze-green on secondaries and their coverts. Purple of belly shades off to bronze-green on flanks. Underwing blackish brown with narrow whitish edges. Bill usually longer than in *pollaratskyi* (997).

MEASUREMENTS

	Wing	Bill (from skull)	Tarsus	Tail

COLOURS OF BARE PARTS. As in 1001.

STARLINGS, MYNAS

171

FIELD CHARACTERS. A gregarious, slim glossy black myna with metallic green and purple reflections, and finely stippled with whitish. Feathers of head, neck and breast pointed and hackle-shaped. Sexes more or less alike; female duller. See Key to the Subspecies and Museum Diagnosis.

STATUS, DISTRIBUTION AND HABITAT. Very common and abundant summer (breeding) visitor to Kashmir (Vale and side valleys up to c. 2100 m) arriving in small numbers at end February, progressing to peak density by 3rd week March or early April. Leaves Kashmir c. October to winter in the north Indian plains alongside the extralimital migratory starlings. May breed also in Himachal Pradesh but no definite evidence as yet. Affects grassy meadows and pastures, mulberry groves, orchards and cultivation in the vicinity of villages.

GENERAL HABITS. Highly gregarious. Keeps in small parties or large flocks of several hundred birds, sauntering or running about purposefully to grub in damp fields, lawns and pastureland. Often in attendance on grazing cattle and sheep, or following the plough in association with Indian Mynas, yellow wagtails and other birds. A feeding flock will, for no apparent reason, suddenly take to the air as if to a given signal and fly up into a nearby tree-top, there to preen and sit around for a while, before gliding down again in twos and threes to resume the foraging. Or the flock will circle around a couple of times in a massed rabble with quick beats of the pointed wings, wheeling and banking in regimented unison, and resettling to feed, seemingly quite unperturbed. Roosts communally in enormous congregations in favourite willow groves, sheesham plantations, reed-beds and the like, flock after flock flying in at sunset from all quarters, sitting clustered thickly on the bare topmost branches, blackening them with their dense multitudes. Roosting preliminaries much less noisy than common mynas'.

FOOD. Chiefly fruits and berries, and insects. Destructive to orchard fruit. In an agricultural area in Punjab (Lyallpur) the following identified among stomach contents: grain and fruit, lizards, spiders, and large quantities of insect pests — grasshoppers (*Chrotogonus* spp.) and locusts (all stages), gram caterpillars, cutworms, beetles, weevils, grubs, pupae of *Chrysopa* sp. (Husain & Bhalla, JBNHS 39: 836).

VOICE AND CALLS. Song typical of Starling: prolonged and varied — a jumble of chattering, clicking and creaky noises mixed with pleasant musical whistles and often some mimicry of other birds' calls. Uttered with verve and persistence, with bill raised to the sky and wings shivering loosely at sides. When approaching a nest under observation, a concerned sharp click, click, reminiscent of a small woodpecker, e.g. *Picoides maharattensis*, 847.

BREEDING. Season, May and June. Nest, an untidy loosely-knit pad of grass and feathers in woodpecker holes in trees (willow, mulberry, chenar, etc.) as well as in holes in earth banks, walls and under rafters of village houses; sometimes amongst heaps of willow twigs stacked up in the branches of trees near villages. Frequently several nests placed fairly close to one another. Eggs, 5 or 6, pale skim-milk blue. Average size of 92 eggs 28.8 × 20.7 mm (BBO). Incubation apparently by both sexes: period unrecorded. Both parents tend the young.
